ANTON BIVENS DAVIS

EARLY TRANSCENDENTALS 10TH EDITION

WILEY PLUS
www.wileyplus.com

# WileyPLUS is a research-based online environment for effective teaching and learning.

*WileyPLUS* builds students' confidence because it takes the guesswork out of studying by providing students with a clear roadmap:

- what to do
- how to do it
- if they did it right

It offers interactive resources along with a complete digital textbook that help students learn more. With *WileyPLUS*, students take more initiative so you'll have greater impact on their achievement in the classroom and beyond.

This book was set in LaTeX by MPS Limited, a Macmillan Company, and printed and bound by R.R. Donnelley/ Jefferson City. The cover was printed by R.R. Donnelley.

This book is printed on acid-free paper.

Founded in 1807, John Wiley & Sons, Inc. has been a valued source of knowledge and understanding for more than 200 years, helping people around the world meet their needs and fulfill their aspirations. Our company is built on a foundation of principles that include responsibility to the communities we serve and where we live and work. In 2008, we launched a Corporate Citizenship Initiative, a global effort to address the environmental, social, economic, and ethical challenges we face in our business. Among the issues we are addressing are carbon impact, paper specifications and procurement, ethical conduct within our business and among our vendors, and community and charitable support. For more information, please visit our website: www.wiley.com/go/citizenship.

The paper in this book was manufactured by a mill whose forest management programs include sustained yield harvesting of its timberlands. Sustained yield harvesting principles ensure that the numbers of trees cut each year does not exceed the amount of new growth.

## About HOWARD ANTON

Howard Anton obtained his B.A. from Lehigh University, his M.A. from the University of Illinois, and his Ph.D. from the Polytechnic University of Brooklyn, all in mathematics. In the early 1960s he worked for Burroughs Corporation and Avco Corporation at Cape Canaveral, Florida, where he was involved with the manned space program. In 1968 he joined the Mathematics Department at Drexel University, where he taught full time until 1983. Since that time he has been an Emeritus Professor at Drexel and has devoted the majority of his time to textbook writing and activities for mathematical associations. Dr. Anton was president of the EPADEL section of the Mathematical Association of America (MAA), served on the Board of Governors of that organization, and guided the creation of the student chapters of the MAA. He has published numerous research papers in functional analysis, approximation theory, and topology, as well as pedagogical papers. He is best known for his textbooks in mathematics, which are among the most widely used in the world. There are currently more than one hundred versions of his books, including translations into Spanish, Arabic, Portuguese, Italian, Indonesian, French, Japanese, Chinese, Hebrew, and German. His textbook in linear algebra has won both the Textbook Excellence Award and the McGuffey Award from the Textbook Author's Association. For relaxation, Dr. Anton enjoys traveling and photography.

## About IRL BIVENS

Irl C. Bivens, recipient of the George Polya Award and the Merten M. Hasse Prize for Expository Writing in Mathematics, received his A.B. from Pfeiffer College and his Ph.D. from the University of North Carolina at Chapel Hill, both in mathematics. Since 1982, he has taught at Davidson College, where he currently holds the position of professor of mathematics. A typical academic year sees him teaching courses in calculus, topology, and geometry. Dr. Bivens also enjoys mathematical history, and his annual History of Mathematics seminar is a perennial favorite with Davidson mathematics majors. He has published numerous articles on undergraduate mathematics, as well as research papers in his specialty, differential geometry. He has served on the editorial boards of the MAA Problem Book series, the MAA Dolciani Mathematical Expositions series and *The College Mathematics Journal*. When he is not pursuing mathematics, Professor Bivens enjoys reading, juggling, swimming, and walking.

## About STEPHEN DAVIS

Stephen L. Davis received his B.A. from Lindenwood College and his Ph.D. from Rutgers University in mathematics. Having previously taught at Rutgers University and Ohio State University, Dr. Davis came to Davidson College in 1981, where he is currently a professor of mathematics. He regularly teaches calculus, linear algebra, abstract algebra, and computer science. A sabbatical in 1995–1996 took him to Swarthmore College as a visiting associate professor. Professor Davis has published numerous articles on calculus reform and testing, as well as research papers on finite group theory, his specialty. Professor Davis has held several offices in the Southeastern section of the MAA, including chair and secretary-treasurer and has served on the MAA Board of Governors. He is currently a faculty consultant for the Educational Testing Service for the grading of the Advanced Placement Calculus Exam, webmaster for the North Carolina Association of Advanced Placement Mathematics Teachers, and is actively involved in nurturing mathematically talented high school students through leadership in the Charlotte Mathematics Club. For relaxation, he plays basketball, juggles, and travels. Professor Davis and his wife Elisabeth have three children, Laura, Anne, and James, all former calculus students.

# PREFACE

This tenth edition of *Calculus* maintains those aspects of previous editions that have led to the series' success—we continue to strive for student comprehension without sacrificing mathematical accuracy, and the exercise sets are carefully constructed to avoid unhappy surprises that can derail a calculus class.

All of the changes to the tenth edition were carefully reviewed by outstanding teachers comprised of both users and nonusers of the previous edition. The charge of this committee was to ensure that all changes did not alter those aspects of the text that attracted users of the ninth edition and at the same time provide freshness to the new edition that would attract new users.

## NEW TO THIS EDITION

- Exercise sets have been modified to correspond more closely to questions in *WileyPLUS*. In addition, more *WileyPLUS* questions now correspond to specific exercises in the text.
- New applied exercises have been added to the book and existing applied exercises have been updated.
- Where appropriate, additional skill/practice exercises were added.

## OTHER FEATURES

**Flexibility** This edition has a built-in flexibility that is designed to serve a broad spectrum of calculus philosophies—from traditional to "reform." Technology can be emphasized or not, and the order of many topics can be permuted freely to accommodate each instructor's specific needs.

**Rigor** The challenge of writing a good calculus book is to strike the right balance between rigor and clarity. Our goal is to present precise mathematics to the fullest extent possible in an introductory treatment. Where clarity and rigor conflict, we choose clarity; however, we believe it to be important that the student understand the difference between a careful proof and an informal argument, so we have informed the reader when the arguments being presented are informal or motivational. Theory involving $\epsilon$-$\delta$ arguments appears in separate sections so that they can be covered or not, as preferred by the instructor.

**Rule of Four** The "rule of four" refers to presenting concepts from the verbal, algebraic, visual, and numerical points of view. In keeping with current pedagogical philosophy, we used this approach whenever appropriate.

**Visualization** This edition makes extensive use of modern computer graphics to clarify concepts and to develop the student's ability to visualize mathematical objects, particularly those in 3-space. For those students who are working with graphing technology, there are

many exercises that are designed to develop the student's ability to generate and analyze mathematical curves and surfaces.

**Quick Check Exercises** Each exercise set begins with approximately five exercises (answers included) that are designed to provide students with an immediate assessment of whether they have mastered key ideas from the section. They require a minimum of computation and are answered by filling in the blanks.

**Focus on Concepts Exercises** Each exercise set contains a clearly identified group of problems that focus on the main ideas of the section.

**Technology Exercises** Most sections include exercises that are designed to be solved using either a graphing calculator or a computer algebra system such as *Mathematica*, *Maple*, or the open source program *Sage*. These exercises are marked with an icon for easy identification.

**Applicability of Calculus** One of the primary goals of this text is to link calculus to the real world and the student's own experience. This theme is carried through in the examples and exercises.

**Career Preparation** This text is written at a mathematical level that will prepare students for a wide variety of careers that require a sound mathematics background, including engineering, the various sciences, and business.

**Trigonometry Review** Deficiencies in trigonometry plague many students, so we have included a substantial trigonometry review in Appendix B.

**Appendix on Polynomial Equations** Because many calculus students are weak in solving polynomial equations, we have included an appendix (Appendix C) that reviews the Factor Theorem, the Remainder Theorem, and procedures for finding rational roots.

**Principles of Integral Evaluation** The traditional Techniques of Integration is entitled "Principles of Integral Evaluation" to reflect its more modern approach to the material. The chapter emphasizes general methods and the role of technology rather than specific tricks for evaluating complicated or obscure integrals.

**Historical Notes** The biographies and historical notes have been a hallmark of this text from its first edition and have been maintained. All of the biographical materials have been distilled from standard sources with the goal of capturing and bringing to life for the student the personalities of history's greatest mathematicians.

**Margin Notes and Warnings** These appear in the margins throughout the text to clarify or expand on the text exposition or to alert the reader to some pitfall.

# SUPPLEMENTS

The **Student Solutions Manual**, which is printed in two volumes, provides detailed solutions to the odd-numbered exercises in the text. The structure of the step-by-step solutions matches those of the worked examples in the textbook. The Student Solutions Manual is also provided in digital format to students in *WileyPLUS*.

Volume I (Single-Variable Calculus, Early Transcendentals) ISBN: 978-1-118-17381-7
Volume II (Multivariable Calculus, Early Transcendentals) ISBN: 978-1-118-17383-1

**The Student Study Guide** is available for download from the book companion Web site at www.wiley.com/college/anton or at www.howardanton.com and to users of *WileyPLUS*.

The **Instructor's Solutions Manual**, which is printed in two volumes, contains detailed solutions to all of the exercises in the text. The Instructor's Solutions Manual is also available in PDF format on the password-protected Instructor Companion Site at www.wiley.com/college/anton or at www.howardanton.com and in *WileyPLUS*.

Volume I (Single-Variable Calculus, Early Transcendentals) ISBN: 978-1-118-17378-7
Volume II (Multivariable Calculus, Early Transcendentals) ISBN: 978-1-118-17379-4

The **Instructor's Manual** suggests time allocations and teaching plans for each section in the text. Most of the teaching plans contain a bulleted list of key points to emphasize. The discussion of each section concludes with a sample homework assignment. The Instructor's Manual is available in PDF format on the password-protected Instructor Companion Site at www.wiley.com/college/anton or at www.howardanton.com and in *WileyPLUS*.

The **Web Projects (Expanding the Calculus Horizon)** referenced in the text can also be downloaded from the companion Web sites and from *WileyPLUS*.

Instructors can also access the following materials from the book companion site or *WileyPLUS*:

- **Interactive Illustrations** can be used in the classroom or computer lab to present and explore key ideas graphically and dynamically. They are especially useful for display of three-dimensional graphs in multivariable calculus.
- The **Computerized Test Bank** features more than 4000 questions—mostly algorithmically generated—that allow for varied questions and numerical inputs.
- The **Printable Test Bank** features questions and answers for every section of the text.
- **PowerPoint lecture slides** cover the major concepts and themes of each section of the book. Personal-Response System questions ("Clicker Questions") appear at the end of each PowerPoint presentation and provide an easy way to gauge classroom understanding.
- **Additional calculus content** covers analytic geometry in calculus, mathematical modeling with differential equations and parametric equations, as well as an introduction to linear algebra.

### *WileyPLUS*

*WileyPLUS*, Wiley's digital-learning environment, is loaded with all of the supplements listed on the previous page, and also features the following:

- **Homework management tools**, which easily allow you to assign and grade algorithmic questions, as well as gauge student comprehension.
- **Algorithmic** questions with randomized numeric values and an answer-entry palette for symbolic notation are provided online though *WileyPLUS*. Students can click on "help" buttons for hints, link to the relevant section of the text, show their work or query their instructor using a white board, or see a step-by-step solution (depending on instructor-selecting settings).
- **Interactive Illustrations** can be used in the classroom or computer lab, or for student practice.
- **QuickStart** predesigned reading and homework assignments. Use them as-is or customize them to fit the needs of your classroom.
- The **e-book**, which is an exact version of the print text but also features hyperlinks to questions, definitions, and supplements for quicker and easier support.
- **Guided Online (GO) Tutorial Exercises** that prompt students to build solutions step by step. Rather than simply grading an exercise answer as wrong, GO tutorial problems show students precisely where they are making a mistake.
- **Are You Ready?** quizzes gauge student mastery of chapter concepts and techniques and provide feedback on areas that require further attention.
- **Algebra and Trigonometry Refresher** quizzes provide students with an opportunity to brush up on the material necessary to master calculus, as well as to determine areas that require further review.

We would also like to thank Celeste Hernandez and Roger Lipsett for their accuracy check of the tenth edition. Thanks also go to Tamas Wiandt for revising the solutions manuals, and Przemyslaw Bogacki for accuracy checking those solutions; Brian Camp and Lyle Smith for their revision of the Student Study Guide; Jim Hartman for his revision of the Instructor's Manual; Ann Ostberg for revising the PowerPoint slides; Beverly Fusfield for creating new GO Tutorials, and Mark McKibben for accuracy checking these new tutorials. We also appreciate the feedback we received from Mark Dunster, Cecelia Knoll, and Michael Rosenthal on selected *WileyPLUS* problems.

# CONTENTS

**0 BEFORE CALCULUS 1**

0.1 Functions 1
0.2 New Functions from Old 15
0.3 Families of Functions 27
0.4 Inverse Functions; Inverse Trigonometric Functions 38
0.5 Exponential and Logarithmic Functions 52

**1 LIMITS AND CONTINUITY 67**

1.1 Limits (An Intuitive Approach) 67
1.2 Computing Limits 80
1.3 Limits at Infinity; End Behavior of a Function 89
1.4 Limits (Discussed More Rigorously) 100
1.5 Continuity 110
1.6 Continuity of Trigonometric, Exponential, and Inverse Functions 121

**2 THE DERIVATIVE 131**

2.1 Tangent Lines and Rates of Change 131
2.2 The Derivative Function 143
2.3 Introduction to Techniques of Differentiation 155
2.4 The Product and Quotient Rules 163
2.5 Derivatives of Trigonometric Functions 169
2.6 The Chain Rule 174

**3 TOPICS IN DIFFERENTIATION 185**

3.1 Implicit Differentiation 185
3.2 Derivatives of Logarithmic Functions 192
3.3 Derivatives of Exponential and Inverse Trigonometric Functions 197
3.4 Related Rates 204
3.5 Local Linear Approximation; Differentials 212
3.6 L'Hôpital's Rule; Indeterminate Forms 219

## 4 THE DERIVATIVE IN GRAPHING AND APPLICATIONS 232

4.1 Analysis of Functions I: Increase, Decrease, and Concavity 232
4.2 Analysis of Functions II: Relative Extrema; Graphing Polynomials 244
4.3 Analysis of Functions III: Rational Functions, Cusps, and Vertical Tangents 254
4.4 Absolute Maxima and Minima 266
4.5 Applied Maximum and Minimum Problems 274
4.6 Rectilinear Motion 288
4.7 Newton's Method 296
4.8 Rolle's Theorem; Mean-Value Theorem 302

## 5 INTEGRATION 316

5.1 An Overview of the Area Problem 316
5.2 The Indefinite Integral 322
5.3 Integration by Substitution 332
5.4 The Definition of Area as a Limit; Sigma Notation 340
5.5 The Definite Integral 353
5.6 The Fundamental Theorem of Calculus 362
5.7 Rectilinear Motion Revisited Using Integration 376
5.8 Average Value of a Function and its Applications 385
5.9 Evaluating Definite Integrals by Substitution 390
5.10 Logarithmic and Other Functions Defined by Integrals 396

## 6 APPLICATIONS OF THE DEFINITE INTEGRAL IN GEOMETRY, SCIENCE, AND ENGINEERING 413

6.1 Area Between Two Curves 413
6.2 Volumes by Slicing; Disks and Washers 421
6.3 Volumes by Cylindrical Shells 432
6.4 Length of a Plane Curve 438
6.5 Area of a Surface of Revolution 444
6.6 Work 449
6.7 Moments, Centers of Gravity, and Centroids 458
6.8 Fluid Pressure and Force 467
6.9 Hyperbolic Functions and Hanging Cables 474

## 7 PRINCIPLES OF INTEGRAL EVALUATION 488

7.1 An Overview of Integration Methods 488
7.2 Integration by Parts 491
7.3 Integrating Trigonometric Functions 500
7.4 Trigonometric Substitutions 508
7.5 Integrating Rational Functions by Partial Fractions 514
7.6 Using Computer Algebra Systems and Tables of Integrals 523

7.7 Numerical Integration; Simpson's Rule 533
7.8 Improper Integrals 547

8 MATHEMATICAL MODELING WITH DIFFERENTIAL EQUATIONS 561
8.1 Modeling with Differential Equations 561
8.2 Separation of Variables 568
8.3 Slope Fields; Euler's Method 579
8.4 First-Order Differential Equations and Applications 586

9 INFINITE SERIES 596
9.1 Sequences 596
9.2 Monotone Sequences 607
9.3 Infinite Series 614
9.4 Convergence Tests 623
9.5 The Comparison, Ratio, and Root Tests 631
9.6 Alternating Series; Absolute and Conditional Convergence 638
9.7 Maclaurin and Taylor Polynomials 648
9.8 Maclaurin and Taylor Series; Power Series 659
9.9 Convergence of Taylor Series 668
9.10 Differentiating and Integrating Power Series; Modeling with Taylor Series 678

10 PARAMETRIC AND POLAR CURVES; CONIC SECTIONS 692
10.1 Parametric Equations; Tangent Lines and Arc Length for Parametric Curves 692
10.2 Polar Coordinates 705
10.3 Tangent Lines, Arc Length, and Area for Polar Curves 719
10.4 Conic Sections 730
10.5 Rotation of Axes; Second-Degree Equations 748
10.6 Conic Sections in Polar Coordinates 754

11 THREE-DIMENSIONAL SPACE; VECTORS 767
11.1 Rectangular Coordinates in 3-Space; Spheres; Cylindrical Surfaces 767
11.2 Vectors 773
11.3 Dot Product; Projections 785
11.4 Cross Product 795
11.5 Parametric Equations of Lines 805
11.6 Planes in 3-Space 813
11.7 Quadric Surfaces 821
11.8 Cylindrical and Spherical Coordinates 832

12 VECTOR-VALUED FUNCTIONS 841
12.1 Introduction to Vector-Valued Functions 841
12.2 Calculus of Vector-Valued Functions 848
12.3 Change of Parameter; Arc Length 858
12.4 Unit Tangent, Normal, and Binormal Vectors 868
12.5 Curvature 873
12.6 Motion Along a Curve 882
12.7 Kepler's Laws of Planetary Motion 895

13 PARTIAL DERIVATIVES 906
13.1 Functions of Two or More Variables 906
13.2 Limits and Continuity 917
13.3 Partial Derivatives 927
13.4 Differentiability, Differentials, and Local Linearity 940
13.5 The Chain Rule 949
13.6 Directional Derivatives and Gradients 960
13.7 Tangent Planes and Normal Vectors 971
13.8 Maxima and Minima of Functions of Two Variables 977
13.9 Lagrange Multipliers 989

14 MULTIPLE INTEGRALS 1000
14.1 Double Integrals 1000
14.2 Double Integrals over Nonrectangular Regions 1009
14.3 Double Integrals in Polar Coordinates 1018
14.4 Surface Area; Parametric Surfaces 1026
14.5 Triple Integrals 1039
14.6 Triple Integrals in Cylindrical and Spherical Coordinates 1048
14.7 Change of Variables in Multiple Integrals; Jacobians 1058
14.8 Centers of Gravity Using Multiple Integrals 1071

15 TOPICS IN VECTOR CALCULUS 1084
15.1 Vector Fields 1084
15.2 Line Integrals 1094
15.3 Independence of Path; Conservative Vector Fields 1111
15.4 Green's Theorem 1122
15.5 Surface Integrals 1130
15.6 Applications of Surface Integrals; Flux 1138
15.7 The Divergence Theorem 1148
15.8 Stokes' Theorem 1158

## THE ROOTS OF CALCULUS

Today's exciting applications of calculus have roots that can be traced to the work of the Greek mathematician Archimedes, but the actual discovery of the fundamental principles of calculus was made independently by Isaac Newton (English) and Gottfried Leibniz (German) in the late seventeenth century. The work of Newton and Leibniz was motivated by four major classes of scientific and mathematical problems of the time:

- Find the tangent line to a general curve at a given point.
- Find the area of a general region, the length of a general curve, and the volume of a general solid.
- Find the maximum or minimum value of a quantity—for example, the maximum and minimum distances of a planet from the Sun, or the maximum range attainable for a projectile by varying its angle of fire.
- Given a formula for the distance traveled by a body in any specified amount of time, find the velocity and acceleration of the body at any instant. Conversely, given a formula that specifies the acceleration of velocity at any instant, find the distance traveled by the body in a specified period of time.

Newton and Leibniz found a fundamental relationship between the problem of finding a tangent line to a curve and the problem of determining the area of a region. Their realization of this connection is considered to be the "discovery of calculus." Though Newton saw how these two problems are related ten years before Leibniz did, Leibniz published his work twenty years before Newton. This situation led to a stormy debate over who was the rightful discoverer of calculus. The debate engulfed Europe for half a century, with the scientists of the European continent supporting Leibniz and those from England supporting Newton. The conflict was extremely unfortunate because Newton's inferior notation badly hampered scientific development in England, and the Continent in turn lost the benefit of Newton's discoveries in astronomy and physics for nearly fifty years. In spite of it all, Newton and Leibniz were sincere admirers of each other's work.

### ISAAC NEWTON (1642–1727)

Newton was born in the village of Woolsthorpe, England. His father died before he was born and his mother raised him on the family farm. As a youth he showed little evidence of his later brilliance, except for an unusual talent with mechanical devices—he apparently built a working water clock and a toy flour mill powered by a mouse. In 1661 he entered Trinity College in Cambridge with a deficiency in geometry. Fortunately, Newton caught the eye of Isaac Barrow, a gifted mathematician and teacher. Under Barrow's guidance Newton immersed himself in mathematics and science, but he graduated without any special distinction. Because the bubonic plague was spreading rapidly through London, Newton returned to his home in Woolsthorpe and stayed there during the years of 1665 and 1666. In those two momentous years the entire framework of modern science was miraculously created in Newton's mind. He discovered calculus, recognized the underlying principles of planetary motion and gravity, and determined that "white" sunlight was composed of all colors, red to violet. For whatever reasons he kept his discoveries to himself. In 1667 he returned to Cambridge to obtain his Master's degree and upon graduation became a teacher at Trinity. Then in 1669 Newton succeeded his teacher, Isaac Barrow, to the Lucasian chair of mathematics at Trinity, one of the most honored chairs of mathematics in the world.

Thereafter, brilliant discoveries flowed from Newton steadily. He formulated the law of gravitation and used it to explain the motion of the moon, the planets, and the tides; he formulated basic theories of light, thermodynamics, and hydrodynamics; and he devised and constructed the first modern reflecting telescope. Throughout his life Newton was hesitant to publish his major discoveries, revealing them only to a select

## THE QUADRATIC FORMULA

The solutions of the quadratic equation $ax^2 + bx + c = 0$ are

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

## THE BINOMIAL FORMULA

$$(x+y)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{1\cdot 2}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}x^{n-3}y^3 + \cdots + nxy^{n-1} + y^n$$

$$(x-y)^n = x^n - nx^{n-1}y + \frac{n(n-1)}{1\cdot 2}x^{n-2}y^2 - \frac{n(n-1)(n-2)}{1\cdot 2\cdot 3}x^{n-3}y^3 + \cdots \pm nxy^{n-1} \mp y^n$$

# TABLE OF INTEGRALS

## BASIC FUNCTIONS

1. $\int u^n\,du = \frac{u^{n+1}}{n+1} + C$
2. $\int \frac{du}{u} = \ln|u| + C$
3. $\int e^u\,du = e^u + C$
4. $\int \sin u\,du = -\cos u + C$
5. $\int \cos u\,du = \sin u + C$
6. $\int \tan u\,du = \ln|\sec u| + C$
7. $\int \sin^{-1} u\,du = u\sin^{-1} u + \sqrt{1-u^2} + C$
8. $\int \cos^{-1} u\,du = u\cos^{-1} u - \sqrt{1-u^2} + C$
9. $\int \tan^{-1} u\,du = u\tan^{-1} u - \ln\sqrt{1+u^2} + C$
10. $\int a^u\,du = \frac{a^u}{\ln a} + C$
11. $\int \ln u\,du = u\ln u - u + C$
12. $\int \cot u\,du = \ln|\sin u| + C$
13. $\int \sec u\,du = \ln|\sec u + \tan u| + C = \ln\left|\tan\left(\frac{1}{4}\pi + \frac{1}{2}u\right)\right| + C$
14. $\int \csc u\,du = \ln|\csc u - \cot u| + C = \ln\left|\tan\frac{1}{2}u\right| + C$
15. $\int \cot^{-1} u\,du = u\cot^{-1} u + \ln\sqrt{1+u^2} + C$
16. $\int \sec^{-1} u\,du = u\sec^{-1} u - \ln\left|u + \sqrt{u^2-1}\right| + C$
17. $\int \csc^{-1} u\,du = u\csc^{-1} u + \ln\left|u + \sqrt{u^2-1}\right| + C$

## RECIPROCALS OF BASIC FUNCTIONS

18. $\displaystyle\int \frac{1}{1 \pm \sin u}\,du = \tan u \mp \sec u + C$

19. $\displaystyle\int \frac{1}{1 \pm \cos u}\,du = -\cot u \pm \csc u + C$

20. $\displaystyle\int \frac{1}{1 \pm \tan u}\,du = \tfrac{1}{2}(u \pm \ln|\cos u \pm \sin u|) + C$

21. $\displaystyle\int \frac{1}{\sin u \cos u}\,du = \ln|\tan u| + C$

22. $\displaystyle\int \frac{1}{1 \pm \cot u}\,du = \tfrac{1}{2}(u \mp \ln|\sin u \pm \cos u|) + C$

23. $\displaystyle\int \frac{1}{1 \pm \sec u}\,du = u + \cot u \mp \csc u + C$

24. $\displaystyle\int \frac{1}{1 \pm \csc u}\,du = u - \tan u \pm \sec u + C$

25. $\displaystyle\int \frac{1}{1 \pm e^u}\,du = u - \ln(1 \pm e^u) + C$

## POWERS OF TRIGONOMETRIC FUNCTIONS

26. $\displaystyle\int \sin^2 u\,du = \tfrac{1}{2}u - \tfrac{1}{4}\sin 2u + C$

27. $\displaystyle\int \cos^2 u\,du = \tfrac{1}{2}u + \tfrac{1}{4}\sin 2u + C$

28. $\displaystyle\int \tan^2 u\,du = \tan u - u + C$

29. $\displaystyle\int \sin^n u\,du = -\frac{1}{n}\sin^{n-1} u\cos u + \frac{n-1}{n}\int \sin^{n-2} u\,du$

30. $\displaystyle\int \cos^n u\,du = \frac{1}{n}\cos^{n-1} u\sin u + \frac{n-1}{n}\int \cos^{n-2} u\,du$

31. $\displaystyle\int \tan^n u\,du = \frac{1}{n-1}\tan^{n-1} u - \int \tan^{n-2} u\,du$

32. $\displaystyle\int \cot^2 u\,du = -\cot u - u + C$

33. $\displaystyle\int \sec^2 u\,du = \tan u + C$

34. $\displaystyle\int \csc^2 u\,du = -\cot u + C$

35. $\displaystyle\int \cot^n u\,du = -\frac{1}{n-1}\cot^{n-1} u - \int \cot^{n-2} u\,du$

36. $\displaystyle\int \sec^n u\,du = \frac{1}{n-1}\sec^{n-2} u\tan u + \frac{n-2}{n-1}\int \sec^{n-2} u\,du$

37. $\displaystyle\int \csc^n u\,du = -\frac{1}{n-1}\csc^{n-2} u\cot u + \frac{n-2}{n-1}\int \csc^{n-2} u\,du$

## PRODUCTS OF TRIGONOMETRIC FUNCTIONS

38. $\displaystyle\int \sin mu\sin nu\,du = -\frac{\sin(m+n)u}{2(m+n)} + \frac{\sin(m-n)u}{2(m-n)} + C$

39. $\displaystyle\int \cos mu\cos nu\,du = \frac{\sin(m+n)u}{2(m+n)} + \frac{\sin(m-n)u}{2(m-n)} + C$

40. $\displaystyle\int \sin mu\cos nu\,du = -\frac{\cos(m+n)u}{2(m+n)} - \frac{\cos(m-n)u}{2(m-n)} + C$

41. $\displaystyle\int \sin^m u\cos^n u\,du = -\frac{\sin^{m-1} u\cos^{n+1} u}{m+n} + \frac{m-1}{m+n}\int \sin^{m-2} u\cos^n u\,du$

$$= \frac{\sin^{m+1} u\cos^{n-1} u}{m+n} + \frac{n-1}{m+n}\int \sin^m u\cos^{n-2} u\,du$$

## PRODUCTS OF TRIGONOMETRIC AND EXPONENTIAL FUNCTIONS

42. $\displaystyle\int e^{au}\sin bu\,du = \frac{e^{au}}{a^2+b^2}(a\sin bu - b\cos bu) + C$

43. $\displaystyle\int e^{au}\cos bu\,du = \frac{e^{au}}{a^2+b^2}(a\cos bu + b\sin bu) + C$

## POWERS OF $u$ MULTIPLYING OR DIVIDING BASIC FUNCTIONS

44. $\displaystyle\int u\sin u\,du = \sin u - u\cos u + C$

45. $\displaystyle\int u\cos u\,du = \cos u + u\sin u + C$

46. $\displaystyle\int u^2\sin u\,du = 2u\sin u + (2-u^2)\cos u + C$

47. $\displaystyle\int u^2\cos u\,du = 2u\cos u + (u^2-2)\sin u + C$

48. $\displaystyle\int u^n\sin u\,du = -u^n\cos u + n\int u^{n-1}\cos u\,du$

49. $\displaystyle\int u^n\cos u\,du = u^n\sin u - n\int u^{n-1}\sin u\,du$

50. $\displaystyle\int u^n\ln u\,du = \frac{u^{n+1}}{(n+1)^2}[(n+1)\ln u - 1] + C$

51. $\displaystyle\int ue^u\,du = e^u(u-1) + C$

52. $\displaystyle\int u^n e^u\,du = u^n e^u - n\int u^{n-1}e^u\,du$

53. $\displaystyle\int u^n a^u\,du = \frac{u^n a^u}{\ln a} - \frac{n}{\ln a}\int u^{n-1}a^u\,du + C$

54. $\displaystyle\int \frac{e^u\,du}{u^n} = -\frac{e^u}{(n-1)u^{n-1}} + \frac{1}{n-1}\int \frac{e^u\,du}{u^{n-1}}$

55. $\displaystyle\int \frac{a^u\,du}{u^n} = -\frac{a^u}{(n-1)u^{n-1}} + \frac{\ln a}{n-1}\int \frac{a^u\,du}{u^{n-1}}$

56. $\displaystyle\int \frac{du}{u\ln u} = \ln|\ln u| + C$

## POLYNOMIALS MULTIPLYING BASIC FUNCTIONS

57. $\displaystyle\int p(u)e^{au}\,du = \frac{1}{a}p(u)e^{au} - \frac{1}{a^2}p'(u)e^{au} + \frac{1}{a^3}p''(u)e^{au} - \cdots$ [signs alternate: $+-+-\cdots$]

58. $\displaystyle\int p(u)\sin au\,du = -\frac{1}{a}p(u)\cos au + \frac{1}{a^2}p'(u)\sin au + \frac{1}{a^3}p''(u)\cos au - \cdots$ [signs alternate in pairs after first term: $++--++--\cdots$]

59. $\displaystyle\int p(u)\cos au\,du = \frac{1}{a}p(u)\sin au + \frac{1}{a^2}p'(u)\cos au - \frac{1}{a^3}p''(u)\sin au - \cdots$ [signs alternate in pairs: $++--++--\cdots$]

# FOR THE STUDENT

Calculus provides a way of viewing and analyzing the physical world. As with all mathematics courses, calculus involves equations and formulas. However, if you successfully learn to use all the formulas and solve all of the problems in the text but do not master the underlying *ideas*, you will have missed the most important part of calculus. If you master these ideas, you will have a widely applicable tool that goes far beyond textbook exercises.

Before starting your studies, you may find it helpful to leaf through this text to get a general feeling for its different parts:

- The opening page of each chapter gives you an overview of what that chapter is about, and the opening page of each section within a chapter gives you an overview of what that section is about. To help you locate specific information, sections are subdivided into topics that are marked with a box like this ■.
- Each section ends with a set of exercises. The answers to most odd-numbered exercises appear in the back of the book. If you find that your answer to an exercise does not match that in the back of the book, do not assume immediately that yours is incorrect—there may be more than one way to express the answer. For example, if your answer is $\sqrt{2}/2$ and the text answer is $1/\sqrt{2}$ , then both are correct since your answer can be obtained by "rationalizing" the text answer. In general, if your answer does not match that in the text, then your best first step is to look for an algebraic manipulation or a trigonometric identity that might help you determine if the two answers are equivalent. If the answer is in the form of a decimal approximation, then your answer might differ from that in the text because of a difference in the number of decimal places used in the computations.
- The section exercises include regular exercises and four special categories: *Quick Check*, *Focus on Concepts*, *True/False*, and *Writing*.
  - The *Quick Check* exercises are intended to give you quick feedback on whether you understand the key ideas in the section; they involve relatively little computation, and have answers provided at the end of the exercise set.
  - The *Focus on Concepts* exercises, as their name suggests, key in on the main ideas in the section.
  - *True/False* exercises focus on key ideas in a different way. You must decide whether the statement is true in *all possible circumstances*, in which case you would declare it to be "true," or whether there are some circumstances in which it is not true, in which case you would declare it to be "false." In each such exercise you are asked to "Explain your answer." You might do this by noting a theorem in the text that shows the statement to be true or by finding a particular example in which the statement is not true.
  - *Writing* exercises are intended to test your ability to explain mathematical ideas in words rather than relying solely on numbers and symbols. All exercises requiring writing should be answered in complete, correctly punctuated logical sentences—not with fragmented phrases and formulas.
- Each chapter ends with two additional sets of exercises: *Chapter Review Exercises*, which, as the name suggests, is a select set of exercises that provide a review of the main concepts and techniques in the chapter, and *Making Connections*, in which exercises require you to draw on and combine various ideas developed throughout the chapter.
- Your instructor may choose to incorporate technology in your calculus course. Exercises whose solution involves the use of some kind of technology are tagged with icons to alert you and your instructor. Those exercises tagged with the icon require graphing technology—either a graphing calculator or a computer program that can graph equations. Those exercises tagged with the icon require a computer algebra system (CAS) such as *Mathematica*, *Maple*, or available on some graphing calculators.
- At the end of the text you will find a set of four appendices covering various topics such as a detailed review of trigonometry and graphing techniques using technology. Inside the front and back covers of the text you will find endpapers that contain useful formulas.
- The ideas in this text were created by real people with interesting personalities and backgrounds. Pictures and biographical sketches of many of these people appear throughout the book.
- Notes in the margin are intended to clarify or comment on important points in the text.

## A Word of Encouragement

As you work your way through this text you will find some ideas that you understand immediately, some that you don't understand until you have read them several times, and others that you do not seem to understand, even after several readings. Do not become discouraged—some ideas are intrinsically difficult and take time to "percolate." You may well find that a hard idea becomes clear later when you least expect it.

# 0 BEFORE CALCULUS

© Arco Images/Alamy

*The development of calculus in the seventeenth and eighteenth centuries was motivated by the need to understand physical phenomena such as the tides, the phases of the moon, the nature of light, and gravity.*

One of the important themes in calculus is the analysis of relationships between physical or mathematical quantities. Such relationships can be described in terms of graphs, formulas, numerical data, or words. In this chapter we will develop the concept of a "function," which is the basic idea that underlies almost all mathematical and physical relationships, regardless of the form in which they are expressed. We will study properties of some of the most basic functions that occur in calculus, including polynomials, trigonometric functions, inverse trigonometric functions, exponential functions, and logarithmic functions.

## 0.1 FUNCTIONS

*In this section we will define and develop the concept of a "function," which is the basic mathematical object that scientists and mathematicians use to describe relationships between variable quantities. Functions play a central role in calculus and its applications.*

### DEFINITION OF A FUNCTION

Many scientific laws and engineering principles describe how one quantity depends on another. This idea was formalized in 1673 by Gottfried Wilhelm Leibniz (see p. xx) who coined the term *function* to indicate the dependence of one quantity on another, as described in the following definition.

**0.1.1 DEFINITION** If a variable $y$ depends on a variable $x$ in such a way that each value of $x$ determines exactly one value of $y$, then we say that ***y is a function of x***.

Four common methods for representing functions are:

- Numerically by tables
- Algebraically by formulas
- Geometrically by graphs
- Verbally

**Table 0.1.1**

INDIANAPOLIS 500 QUALIFYING SPEEDS

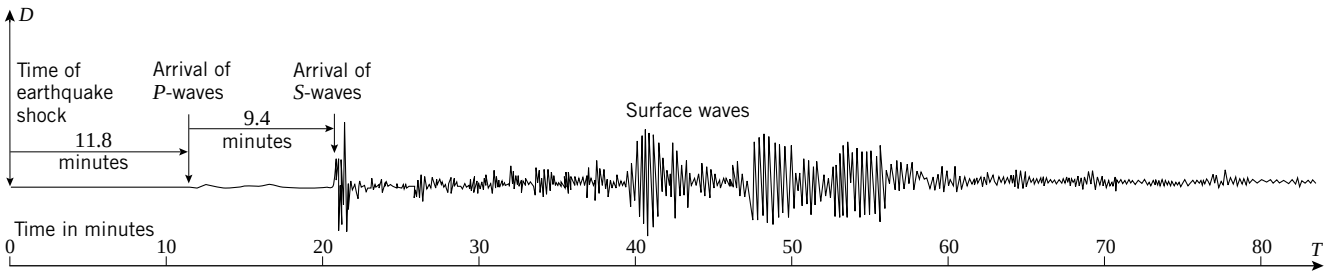
| YEAR $t$ | SPEED $S$ (mi/h) |
|---|---|
| 1994 | 228.011 |
| 1995 | 231.604 |
| 1996 | 233.100 |
| 1997 | 218.263 |
| 1998 | 223.503 |
| 1999 | 225.179 |
| 2000 | 223.471 |
| 2001 | 226.037 |
| 2002 | 231.342 |
| 2003 | 231.725 |
| 2004 | 222.024 |
| 2005 | 227.598 |
| 2006 | 228.985 |
| 2007 | 225.817 |
| 2008 | 226.366 |
| 2009 | 224.864 |
| 2010 | 227.970 |
| 2011 | 227.472 |

The method of representation often depends on how the function arises. For example:

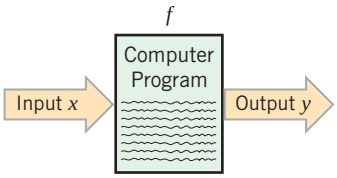
- Table 0.1.1 shows the top qualifying speed $S$ for the Indianapolis 500 auto race as a function of the year $t$. There is exactly one value of $S$ for each value of $t$.
- Figure 0.1.1 is a graphical record of an earthquake recorded on a seismograph. The graph describes the deflection $D$ of the seismograph needle as a function of the time $T$ elapsed since the wave left the earthquake's epicenter. There is exactly one value of $D$ for each value of $T$.
- Some of the most familiar functions arise from formulas; for example, the formula $C = 2\pi r$ expresses the circumference $C$ of a circle as a function of its radius $r$. There is exactly one value of $C$ for each value of $r$.
- Sometimes functions are described in words. For example, Isaac Newton's Law of Universal Gravitation is often stated as follows: The gravitational force of attraction between two bodies in the Universe is directly proportional to the product of their masses and inversely proportional to the square of the distance between them. This is the verbal description of the formula

$$F = G\frac{m_1 m_2}{r^2}$$

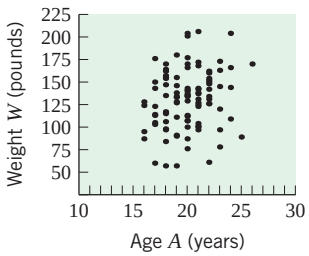
in which $F$ is the force of attraction, $m_1$ and $m_2$ are the masses, $r$ is the distance between them, and $G$ is a constant. If the masses are constant, then the verbal description defines $F$ as a function of $r$. There is exactly one value of $F$ for each value of $r$.



▲ **Figure 0.1.1**



▲ **Figure 0.1.2**



▲ **Figure 0.1.3**

In the mid-eighteenth century the Swiss mathematician Leonhard Euler (pronounced "oiler") conceived the idea of denoting functions by letters of the alphabet, thereby making it possible to refer to functions without stating specific formulas, graphs, or tables. To understand Euler's idea, think of a function as a computer program that takes an *input* $x$, operates on it in some way, and produces exactly one *output* $y$. The computer program is an object in its own right, so we can give it a name, say $f$. Thus, the function $f$ (the computer program) associates a unique output $y$ with each input $x$ (Figure 0.1.2). This suggests the following definition.

**0.1.2 DEFINITION** A ***function*** $f$ is a rule that associates a unique output with each input. If the input is denoted by $x$, then the output is denoted by $f(x)$ (read "$f$ of $x$").

In this definition the term *unique* means "exactly one." Thus, a function cannot assign two different outputs to the same input. For example, Figure 0.1.3 shows a plot of weight versus age for a random sample of 100 college students. This plot does *not* describe $W$ as a function of $A$ because there are some values of $A$ with more than one corresponding

value of $W$. This is to be expected, since two people with the same age can have different weights.

## INDEPENDENT AND DEPENDENT VARIABLES

For a given input $x$, the output of a function $f$ is called the ***value*** of $f$ at $x$ or the ***image*** of $x$ under $f$. Sometimes we will want to denote the output by a single letter, say $y$, and write

$$y = f(x)$$

This equation expresses $y$ as a function of $x$; the variable $x$ is called the ***independent variable*** (or ***argument***) of $f$, and the variable $y$ is called the ***dependent variable*** of $f$. This terminology is intended to suggest that $x$ is free to vary, but that once $x$ has a specific value a corresponding value of $y$ is determined. For now we will only consider functions in which the independent and dependent variables are real numbers, in which case we say that $f$ is a ***real-valued function of a real variable***. Later, we will consider other kinds of functions.

**Table 0.1.2**

| $x$ | 0 | 1 | 2 | 3 |
|---|---|---|---|---|
| $y$ | 3 | 4 | −1 | 6 |

▶ **Example 1** Table 0.1.2 describes a functional relationship $y = f(x)$ for which

$f(0) = 3$ — $f$ associates $y = 3$ with $x = 0$.

$f(1) = 4$ — $f$ associates $y = 4$ with $x = 1$.

$f(2) = -1$ — $f$ associates $y = -1$ with $x = 2$.

$f(3) = 6$ — $f$ associates $y = 6$ with $x = 3$. ◀

▶ **Example 2** The equation

$$y = 3x^2 - 4x + 2$$

has the form $y = f(x)$ in which the function $f$ is given by the formula

$$f(x) = 3x^2 - 4x + 2$$

**Leonhard Euler (1707–1783)** Euler was probably the most prolific mathematician who ever lived. It has been said that "Euler wrote mathematics as effortlessly as most men breathe." He was born in Basel, Switzerland, and was the son of a Protestant minister who had himself studied mathematics. Euler's genius developed early. He attended the University of Basel, where by age 16 he obtained both a Bachelor of Arts degree and a Master's degree in philosophy. While at Basel, Euler had the good fortune to be tutored one day a week in mathematics by a distinguished mathematician, Johann Bernoulli. At the urging of his father, Euler then began to study theology. The lure of mathematics was too great, however, and by age 18 Euler had begun to do mathematical research. Nevertheless, the influence of his father and his theological studies remained, and throughout his life Euler was a deeply religious, unaffected person. At various times Euler taught at St. Petersburg Academy of Sciences (in Russia), the University of Basel, and the Berlin Academy of Sciences. Euler's energy and capacity for work were virtually boundless. His collected works form more than 100 quarto-sized volumes and it is believed that much of his work has been lost. What is particularly astonishing is that Euler was blind for the last 17 years of his life, and this was one of his most productive periods! Euler's flawless memory was phenomenal. Early in his life he memorized the entire *Aeneid* by Virgil, and at age 70 he could not only recite the entire work but could also state the first and last sentence on each page of the book from which he memorized the work. His ability to solve problems in his head was beyond belief. He worked out in his head major problems of lunar motion that baffled Isaac Newton and once did a complicated calculation in his head to settle an argument between two students whose computations differed in the fiftieth decimal place.

Following the development of calculus by Leibniz and Newton, results in mathematics developed rapidly in a disorganized way. Euler's genius gave coherence to the mathematical landscape. He was the first mathematician to bring the full power of calculus to bear on problems from physics. He made major contributions to virtually every branch of mathematics as well as to the theory of optics, planetary motion, electricity, magnetism, and general mechanics.

[*Image: http://commons.wikimedia.org/wiki/File:Leonhard_Euler_by_Handmann_.png*]

For each input $x$, the corresponding output $y$ is obtained by substituting $x$ in this formula. For example,

$$f(0) = 3(0)^2 - 4(0) + 2 = 2$$ — $f$ associates $y = 2$ with $x = 0$.

$$f(-1.7) = 3(-1.7)^2 - 4(-1.7) + 2 = 17.47$$ — $f$ associates $y = 17.47$ with $x = -1.7$.

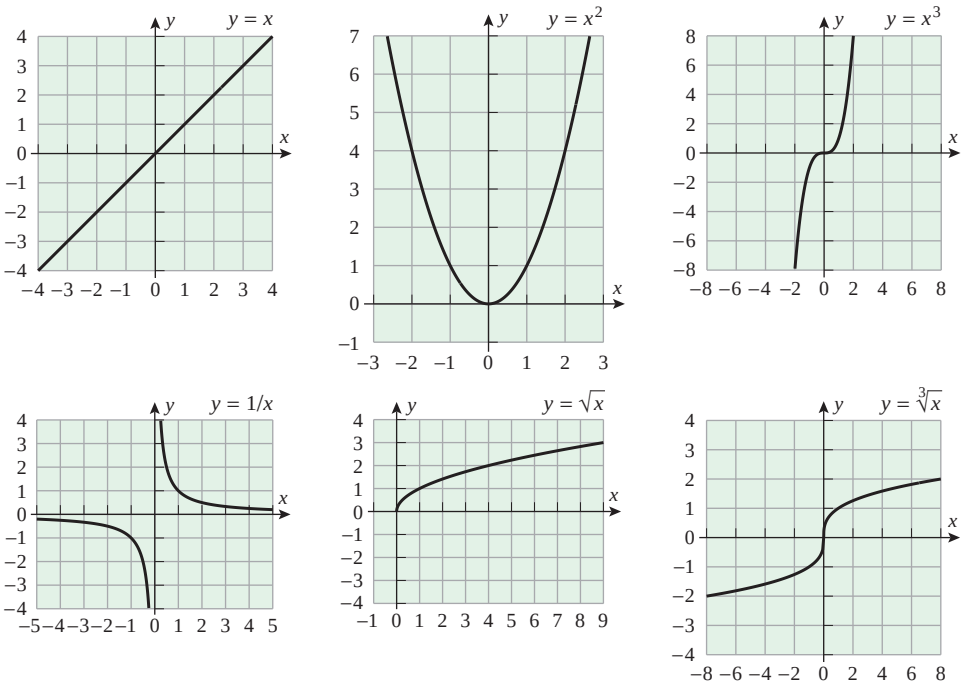
$$f(\sqrt{2}) = 3(\sqrt{2})^2 - 4\sqrt{2} + 2 = 8 - 4\sqrt{2}$$ — $f$ associates $y = 8 - 4\sqrt{2}$ with $x = \sqrt{2}$. ◀

## GRAPHS OF FUNCTIONS

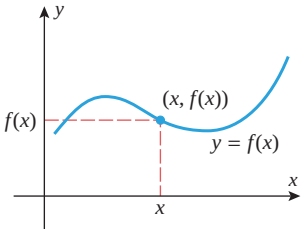
If $f$ is a real-valued function of a real variable, then the ***graph*** of $f$ in the $xy$-plane is defined to be the graph of the equation $y = f(x)$. For example, the graph of the function $f(x) = x$ is the graph of the equation $y = x$, shown in Figure 0.1.4. That figure also shows the graphs of some other basic functions that may already be familiar to you. In Appendix A we discuss techniques for graphing functions using graphing technology.

Figure 0.1.4 shows only portions of the graphs. Where appropriate, and unless indicated otherwise, it is understood that graphs shown in this text extend indefinitely beyond the boundaries of the displayed figure.

Since $\sqrt{x}$ is imaginary for negative values of $x$, there are no points on the graph of $y = \sqrt{x}$ in the region where $x < 0$.



▲ **Figure 0.1.4**



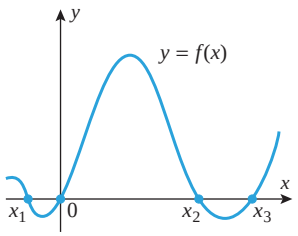
▲ **Figure 0.1.5** The $y$-coordinate of a point on the graph of $y = f(x)$ is the value of $f$ at the corresponding $x$-coordinate.

Graphs can provide valuable visual information about a function. For example, since the graph of a function $f$ in the $xy$-plane is the graph of the equation $y = f(x)$, the points on the graph of $f$ are of the form $(x, f(x))$; that is, *the $y$-coordinate of a point on the graph of $f$ is the value of $f$ at the corresponding $x$-coordinate* (Figure 0.1.5). The values of $x$ for which $f(x) = 0$ are the $x$-coordinates of the points where the graph of $f$ intersects the $x$-axis (Figure 0.1.6). These values are called the ***zeros*** of $f$, the ***roots*** of $f(x) = 0$, or the ***x-intercepts*** of the graph of $y = f(x)$.

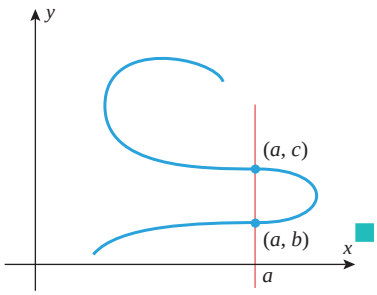
## THE VERTICAL LINE TEST

Not every curve in the $xy$-plane is the graph of a function. For example, consider the curve in Figure 0.1.7, which is cut at two distinct points, $(a, b)$ and $(a, c)$, by a vertical line. This curve cannot be the graph of $y = f(x)$ for any function $f$; otherwise, we would have

$$f(a) = b \quad \text{and} \quad f(a) = c$$

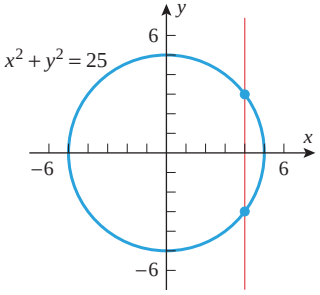


▲ **Figure 0.1.6** $f$ has zeros at $x_1$, 0, $x_2$, and $x_3$.



▲ **Figure 0.1.7** This curve cannot be the graph of a function.

Symbols such as $+x$ and $-x$ are deceptive, since it is tempting to conclude that $+x$ is positive and $-x$ is negative. However, this need not be so, since $x$ itself can be positive or negative. For example, if $x$ is negative, say $x = -3$, then $-x = 3$ is positive and $+x = -3$ is negative.



▲ **Figure 0.1.8**

**WARNING**

To denote the negative square root you must write $-\sqrt{x}$. For example, the positive square root of 9 is $\sqrt{9} = 3$, whereas the negative square root of 9 is $-\sqrt{9} = -3$. (Do not make the mistake of writing $\sqrt{9} = \pm 3$.)

which is impossible, since $f$ cannot assign two different values to $a$. Thus, there is no function $f$ whose graph is the given curve. This illustrates the following general result, which we will call the ***vertical line test***.

**0.1.3 THE VERTICAL LINE TEST** *A curve in the xy-plane is the graph of some function $f$ if and only if no vertical line intersects the curve more than once.*

▶ **Example 3** The graph of the equation

$$x^2 + y^2 = 25$$

is a circle of radius 5 centered at the origin and hence there are vertical lines that cut the graph more than once (Figure 0.1.8). Thus this equation does not define $y$ as a function of $x$. ◀

## THE ABSOLUTE VALUE FUNCTION

Recall that the ***absolute value*** or ***magnitude*** of a real number $x$ is defined by

$$|x| = \begin{cases} x, & x \geq 0 \\ -x, & x < 0 \end{cases}$$

The effect of taking the absolute value of a number is to strip away the minus sign if the number is negative and to leave the number unchanged if it is nonnegative. Thus,

$$|5| = 5, \quad \left|-\tfrac{4}{7}\right| = \tfrac{4}{7}, \quad |0| = 0$$

A more detailed discussion of the properties of absolute value is given in Web Appendix F. However, for convenience we provide the following summary of its algebraic properties.

**0.1.4 PROPERTIES OF ABSOLUTE VALUE** *If $a$ and $b$ are real numbers, then*

| | | |
|---|---|---|
| $(a)$ | $\lvert -a\rvert = \lvert a\rvert$ | A number and its negative have the same absolute value. |
| $(b)$ | $\lvert ab\rvert = \lvert a\rvert\,\lvert b\rvert$ | The absolute value of a product is the product of the absolute values. |
| $(c)$ | $\lvert a/b\rvert = \lvert a\rvert/\lvert b\rvert,\ b \neq 0$ | The absolute value of a ratio is the ratio of the absolute values. |
| $(d)$ | $\lvert a + b\rvert \leq \lvert a\rvert + \lvert b\rvert$ | The ***triangle inequality*** |

The graph of the function $f(x) = |x|$ can be obtained by graphing the two parts of the equation

$$y = \begin{cases} x, & x \geq 0 \\ -x, & x < 0 \end{cases}$$

separately. Combining the two parts produces the V-shaped graph in Figure 0.1.9.

Absolute values have important relationships to square roots. To see why this is so, recall from algebra that every positive real number $x$ has two square roots, one positive and one negative. By definition, the symbol $\sqrt{x}$ denotes the *positive* square root of $x$.

Care must be exercised in simplifying expressions of the form $\sqrt{x^2}$, since it is *not* always true that $\sqrt{x^2} = x$. This equation is correct if $x$ is nonnegative, but it is false if $x$ is negative. For example, if $x = -4$, then

$$\sqrt{x^2} = \sqrt{(-4)^2} = \sqrt{16} = 4 \neq x$$

**TECHNOLOGY MASTERY**

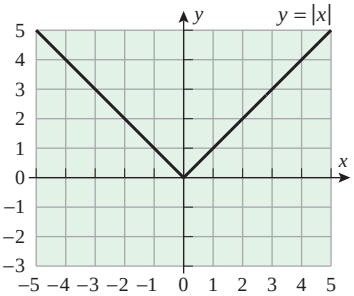
Verify (1) by using a graphing utility to show that the equations $y = \sqrt{x^2}$ and $y = |x|$ have the same graph.

A statement that is correct for all real values of $x$ is

$$\sqrt{x^2} = |x| \tag{1}$$

## PIECEWISE-DEFINED FUNCTIONS

The absolute value function $f(x) = |x|$ is an example of a function that is defined ***piecewise*** in the sense that the formula for $f$ changes, depending on the value of $x$.

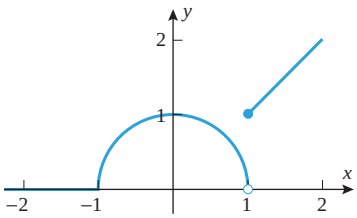


▲ **Figure 0.1.9**

**▶ Example 4** Sketch the graph of the function defined piecewise by the formula

$$f(x) = \begin{cases} 0, & x \le -1 \\ \sqrt{1 - x^2}, & -1 < x < 1 \\ x, & x \ge 1 \end{cases}$$

***Solution.*** The formula for $f$ changes at the points $x = -1$ and $x = 1$. (We call these the ***breakpoints*** for the formula.) A good procedure for graphing functions defined piecewise is to graph the function separately over the open intervals determined by the breakpoints, and then graph $f$ at the breakpoints themselves. For the function $f$ in this example the graph is the horizontal ray $y = 0$ on the interval $(-\infty, -1]$, it is the semicircle $y = \sqrt{1 - x^2}$ on the interval $(-1, 1)$, and it is the ray $y = x$ on the interval $[1, +\infty)$. The formula for $f$ specifies that the equation $y = 0$ applies at the breakpoint $-1$ [so $y = f(-1) = 0$], and it specifies that the equation $y = x$ applies at the breakpoint 1 [so $y = f(1) = 1$]. The graph of $f$ is shown in Figure 0.1.10. ◀



▲ **Figure 0.1.10**

**REMARK** In Figure 0.1.10 the solid dot and open circle at the breakpoint $x = 1$ serve to emphasize that the point on the graph lies on the ray and not the semicircle. There is no ambiguity at the breakpoint $x = -1$ because the two parts of the graph join together continuously there.

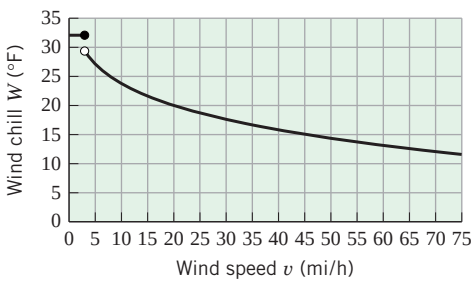
© Brian Horisk/Alamy

*The wind chill index measures the sensation of coldness that we feel from the combined effect of temperature and wind speed.*

**▶ Example 5** Increasing the speed at which air moves over a person's skin increases the rate of moisture evaporation and makes the person feel cooler. (This is why we fan ourselves in hot weather.) The ***wind chill index*** is the temperature at a wind speed of 4 mi/h that would produce the same sensation on exposed skin as the current temperature and wind speed combination. An empirical formula (i.e., a formula based on experimental data) for the wind chill index $W$ at 32°F for a wind speed of $v$ mi/h is

$$W = \begin{cases} 32, & 0 \le v \le 3 \\ 55.628 - 22.07v^{0.16}, & 3 < v \end{cases}$$

A computer-generated graph of $W(v)$ is shown in Figure 0.1.11. ◀



▶ **Figure 0.1.11** Wind chill versus wind speed at 32°F

## DOMAIN AND RANGE

If $x$ and $y$ are related by the equation $y = f(x)$, then the set of all allowable inputs ($x$-values) is called the ***domain*** of $f$, and the set of outputs ($y$-values) that result when $x$ varies over the domain is called the ***range*** of $f$. For example, if $f$ is the function defined by the table in Example 1, then the domain is the set $\{0, 1, 2, 3\}$ and the range is the set $\{-1, 3, 4, 6\}$.

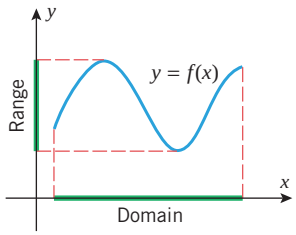
Sometimes physical or geometric considerations impose restrictions on the allowable inputs of a function. For example, if $y$ denotes the area of a square of side $x$, then these variables are related by the equation $y = x^2$. Although this equation produces a unique value of $y$ for every real number $x$, the fact that lengths must be nonnegative imposes the requirement that $x \geq 0$.

One might argue that a physical square cannot have a side of length zero. However, it is often convenient mathematically to allow zero lengths, and we will do so throughout this text where appropriate.

When a function is defined by a mathematical formula, the formula itself may impose restrictions on the allowable inputs. For example, if $y = 1/x$, then $x = 0$ is not an allowable input since division by zero is undefined, and if $y = \sqrt{x}$, then negative values of $x$ are not allowable inputs because they produce imaginary values for $y$ and we have agreed to consider only real-valued functions of a real variable. In general, we make the following definition.

**0.1.5 DEFINITION** If a real-valued function of a real variable is defined by a formula, and if no domain is stated explicitly, then it is to be understood that the domain consists of all real numbers for which the formula yields a real value. This is called the ***natural domain*** of the function.

The domain and range of a function $f$ can be pictured by projecting the graph of $y = f(x)$ onto the coordinate axes as shown in Figure 0.1.12.



▲ **Figure 0.1.12** The projection of $y = f(x)$ on the $x$-axis is the set of allowable $x$-values for $f$, and the projection on the $y$-axis is the set of corresponding $y$-values.

▶ **Example 6** Find the natural domain of

(a) $f(x) = x^3$ (b) $f(x) = 1/[(x-1)(x-3)]$

(c) $f(x) = \tan x$ (d) $f(x) = \sqrt{x^2 - 5x + 6}$

***Solution (a).*** The function $f$ has real values for all real $x$, so its natural domain is the interval $(-\infty, +\infty)$.

***Solution (b).*** The function $f$ has real values for all real $x$, except $x = 1$ and $x = 3$, where divisions by zero occur. Thus, the natural domain is

$$\{x : x \neq 1 \text{ and } x \neq 3\} = (-\infty, 1) \cup (1, 3) \cup (3, +\infty)$$

***Solution (c).*** Since $f(x) = \tan x = \sin x / \cos x$, the function $f$ has real values except where $\cos x = 0$, and this occurs when $x$ is an odd integer multiple of $\pi/2$. Thus, the natural domain consists of all real numbers except

$$x = \pm\frac{\pi}{2}, \pm\frac{3\pi}{2}, \pm\frac{5\pi}{2}, \ldots$$

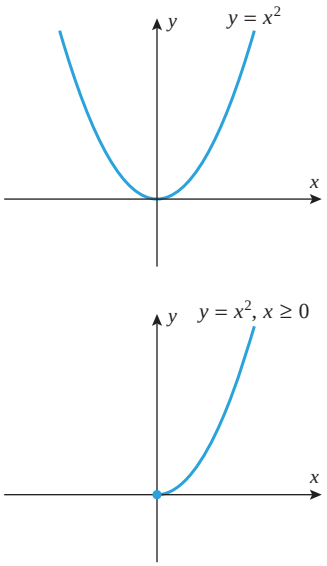
For a review of trigonometry see Appendix B.

***Solution (d).*** The function $f$ has real values, except when the expression inside the radical is negative. Thus the natural domain consists of all real numbers $x$ such that

$$x^2 - 5x + 6 = (x-3)(x-2) \geq 0$$

This inequality is satisfied if $x \leq 2$ or $x \geq 3$ (verify), so the natural domain of $f$ is

$$(-\infty, 2] \cup [3, +\infty) \quad \blacktriangleleft$$



▲ Figure 0.1.13

In some cases we will state the domain explicitly when defining a function. For example, if $f(x) = x^2$ is the area of a square of side $x$, then we can write

$$f(x) = x^2, \quad x \geq 0$$

to indicate that we take the domain of $f$ to be the set of nonnegative real numbers (Figure 0.1.13).

## THE EFFECT OF ALGEBRAIC OPERATIONS ON THE DOMAIN

Algebraic expressions are frequently simplified by canceling common factors in the numerator and denominator. However, care must be exercised when simplifying formulas for functions in this way, since this process can alter the domain.

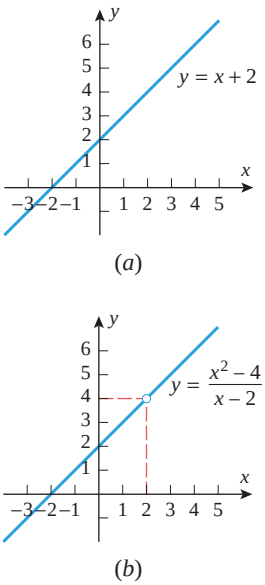
**▶ Example 7** The natural domain of the function

$$f(x) = \frac{x^2 - 4}{x - 2} \tag{2}$$

consists of all real $x$ except $x = 2$. However, if we factor the numerator and then cancel the common factor in the numerator and denominator, we obtain

$$f(x) = \frac{(x-2)(x+2)}{x-2} = x + 2 \tag{3}$$

Since the right side of (3) has a value of $f(2) = 4$ and $f(2)$ was undefined in (2), the algebraic simplification has changed the function. Geometrically, the graph of (3) is the line in Figure 0.1.14*a*, whereas the graph of (2) is the same line but with a hole at $x = 2$, since the function is undefined there (Figure 0.1.14*b*). In short, the geometric effect of the algebraic cancellation is to eliminate the hole in the original graph. ◀



▲ Figure 0.1.14

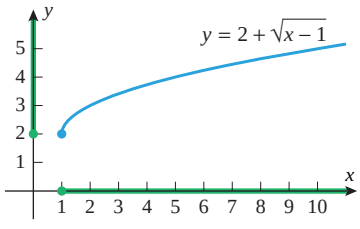
Sometimes alterations to the domain of a function that result from algebraic simplification are irrelevant to the problem at hand and can be ignored. However, if the domain must be preserved, then one must impose the restrictions on the simplified function explicitly. For example, if we wanted to preserve the domain of the function in Example 7, then we would have to express the simplified form of the function as

$$f(x) = x + 2, \quad x \neq 2$$

**▶ Example 8** Find the domain and range of

(a) $f(x) = 2 + \sqrt{x-1}$ (b) $f(x) = (x+1)/(x-1)$

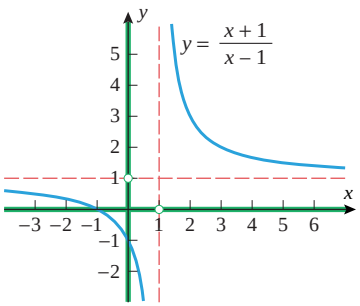
***Solution (a).*** Since no domain is stated explicitly, the domain of $f$ is its natural domain, $[1, +\infty)$. As $x$ varies over the interval $[1, +\infty)$, the value of $\sqrt{x-1}$ varies over the interval $[0, +\infty)$, so the value of $f(x) = 2 + \sqrt{x-1}$ varies over the interval $[2, +\infty)$, which is the range of $f$. The domain and range are highlighted in green on the $x$- and $y$-axes in Figure 0.1.15.



▲ Figure 0.1.15

***Solution (b).*** The given function $f$ is defined for all real $x$, except $x = 1$, so the natural domain of $f$ is

$$\{x : x \neq 1\} = (-\infty, 1) \cup (1, +\infty)$$



▲ Figure 0.1.16

To determine the range it will be convenient to introduce a dependent variable

$$y = \frac{x+1}{x-1} \tag{4}$$

Although the set of possible $y$-values is not immediately evident from this equation, the graph of (4), which is shown in Figure 0.1.16, suggests that the range of $f$ consists of all $y$, except $y = 1$. To see that this is so, we solve (4) for $x$ in terms of $y$:

$$\begin{aligned} (x-1)y &= x+1 \\ xy - y &= x+1 \\ xy - x &= y+1 \\ x(y-1) &= y+1 \\ x &= \frac{y+1}{y-1} \end{aligned}$$

It is now evident from the right side of this equation that $y = 1$ is not in the range; otherwise we would have a division by zero. No other values of $y$ are excluded by this equation, so the range of the function $f$ is $\{y : y \neq 1\} = (-\infty, 1) \cup (1, +\infty)$, which agrees with the result obtained graphically. ◄

## DOMAIN AND RANGE IN APPLIED PROBLEMS

In applications, physical considerations often impose restrictions on the domain and range of a function.

► **Example 9** An open box is to be made from a 16-inch by 30-inch piece of cardboard by cutting out squares of equal size from the four corners and bending up the sides (Figure 0.1.17*a*).

(a) Let $V$ be the volume of the box that results when the squares have sides of length $x$. Find a formula for $V$ as a function of $x$.

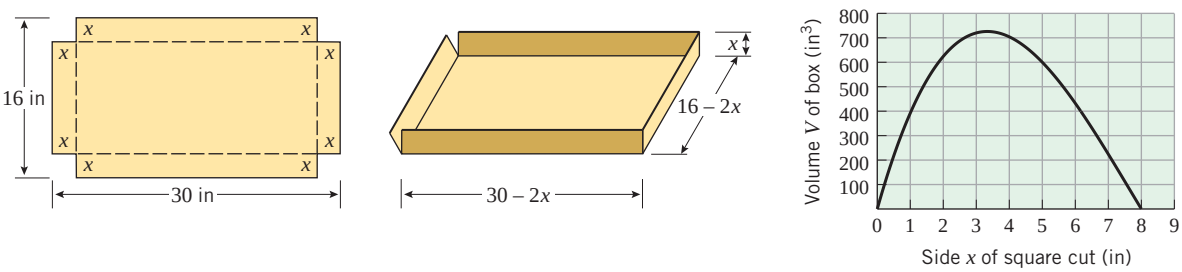
(b) Find the domain of $V$.

(c) Use the graph of $V$ given in Figure 0.1.17*c* to estimate the range of $V$.

(d) Describe in words what the graph tells you about the volume.

***Solution (a).*** As shown in Figure 0.1.17*b*, the resulting box has dimensions $16 - 2x$ by $30 - 2x$ by $x$, so the volume $V(x)$ is given by

$$V(x) = (16 - 2x)(30 - 2x)x = 480x - 92x^2 + 4x^3$$



(*a*) (*b*) (*c*)

▲ Figure 0.1.17

***Solution (b).*** The domain is the set of $x$-values and the range is the set of $V$-values. Because $x$ is a length, it must be nonnegative, and because we cannot cut out squares whose sides are more than 8 in long (why?), the $x$-values in the domain must satisfy

$$0 \le x \le 8$$

***Solution (c).*** From the graph of $V$ versus $x$ in Figure 0.1.17$c$ we estimate that the $V$-values in the range satisfy

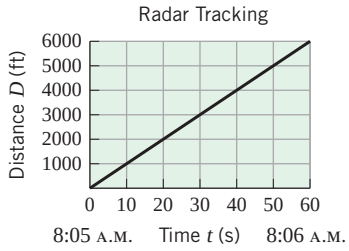
$$0 \le V \le 725$$

Note that this is an approximation. Later we will show how to find the range exactly.

***Solution (d).*** The graph tells us that the box of maximum volume occurs for a value of $x$ that is between 3 and 4 and that the maximum volume is approximately 725 $\text{in}^3$. The graph also shows that the volume decreases toward zero as $x$ gets closer to 0 or 8, which should make sense to you intuitively. ◄

In applications involving time, formulas for functions are often expressed in terms of a variable $t$ whose starting value is taken to be $t = 0$.

► **Example 10** At 8:05 A.M. a car is clocked at 100 ft/s by a radar detector that is positioned at the edge of a straight highway. Assuming that the car maintains a constant speed between 8:05 A.M. and 8:06 A.M., find a function $D(t)$ that expresses the distance traveled by the car during that time interval as a function of the time $t$.



▲ **Figure 0.1.18**

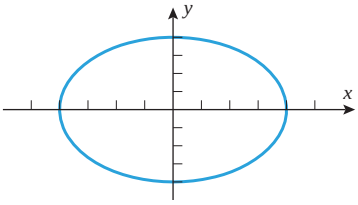
***Solution.*** It would be clumsy to use the actual clock time for the variable $t$, so let us agree to use the *elapsed* time in seconds, starting with $t = 0$ at 8:05 A.M. and ending with $t = 60$ at 8:06 A.M. At each instant, the distance traveled (in ft) is equal to the speed of the car (in ft/s) multiplied by the elapsed time (in s). Thus,

$$D(t) = 100t, \quad 0 \le t \le 60$$

The graph of $D$ versus $t$ is shown in Figure 0.1.18. ◄

## ISSUES OF SCALE AND UNITS

In geometric problems where you want to preserve the "true" shape of a graph, you must use units of equal length on both axes. For example, if you graph a circle in a coordinate system in which 1 unit in the $y$-direction is smaller than 1 unit in the $x$-direction, then the circle will be squashed vertically into an elliptical shape (Figure 0.1.19).



The circle is squashed because 1 unit on the $y$-axis has a smaller length than 1 unit on the $x$-axis.

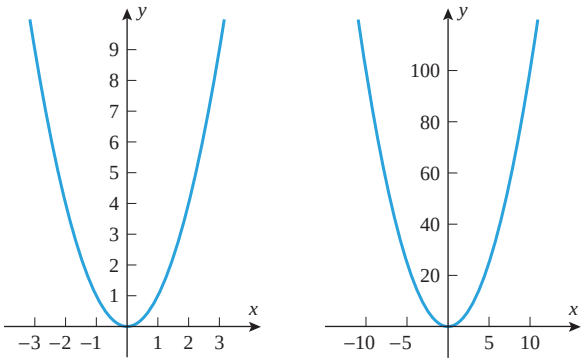
▲ **Figure 0.1.19**

In applications where the variables on the two axes have unrelated units (say, centimeters on the $y$-axis and seconds on the $x$-axis), then nothing is gained by requiring the units to have equal lengths; choose the lengths to make the graph as clear as possible.

However, sometimes it is inconvenient or impossible to display a graph using units of equal length. For example, consider the equation

$$y = x^2$$

If we want to show the portion of the graph over the interval $-3 \le x \le 3$, then there is no problem using units of equal length, since $y$ only varies from 0 to 9 over that interval. However, if we want to show the portion of the graph over the interval $-10 \le x \le 10$, then there is a problem keeping the units equal in length, since the value of $y$ varies between 0 and 100. In this case the only reasonable way to show all of the graph that occurs over the interval $-10 \le x \le 10$ is to compress the unit of length along the $y$-axis, as illustrated in Figure 0.1.20.



▶ **Figure 0.1.20**

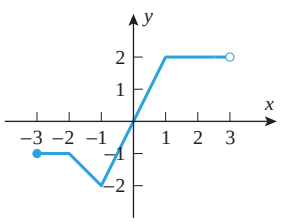
## ✔ QUICK CHECK EXERCISES 0.1 *(See page 15 for answers.)*

**1.** Let $f(x) = \sqrt{x+1} + 4$.
(a) The natural domain of $f$ is _____.
(b) $f(3) =$ _____
(c) $f(t^2 - 1) =$ _____
(d) $f(x) = 7$ if $x =$ _____
(e) The range of $f$ is _____.

**2.** Line segments in an $xy$-plane form "letters" as depicted.

(a) If the $y$-axis is parallel to the letter I, which of the letters represent the graph of $y = f(x)$ for some function $f$?
(b) If the $y$-axis is perpendicular to the letter I, which of the letters represent the graph of $y = f(x)$ for some function $f$?

**3.** The accompanying figure shows the complete graph of $y = f(x)$.
(a) The domain of $f$ is _____.
(b) The range of $f$ is _____.
(c) $f(-3) =$ _____
(d) $f\left(\frac{1}{2}\right) =$ _____
(e) The solutions to $f(x) = -\frac{3}{2}$ are $x =$ _____ and $x =$ _____.



◀ **Figure Ex-3**

**4.** The accompanying table gives a 5-day forecast of high and low temperatures in degrees Fahrenheit (°F).
(a) Suppose that $x$ and $y$ denote the respective high and low temperature predictions for each of the 5 days. Is $y$ a function of $x$? If so, give the domain and range of this function.
(b) Suppose that $x$ and $y$ denote the respective low and high temperature predictions for each of the 5 days. Is $y$ a function of $x$? If so, give the domain and range of this function.

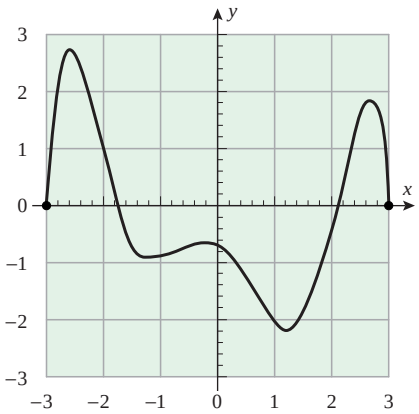
| | MON | TUE | WED | THURS | FRI |
|---|---|---|---|---|---|
| HIGH | 75 | 71 | 65 | 70 | 73 |
| LOW | 52 | 56 | 48 | 50 | 52 |

▲ **Table Ex-4**

**5.** Let $l$, $w$, and $A$ denote the length, width, and area of a rectangle, respectively, and suppose that the width of the rectangle is half the length.
(a) If $l$ is expressed as a function of $w$, then $l =$ _____.
(b) If $A$ is expressed as a function of $l$, then $A =$ _____.
(c) If $w$ is expressed as a function of $A$, then $w =$ _____.

## EXERCISE SET 0.1 Graphing Utility

**1.** Use the accompanying graph to answer the following questions, making reasonable approximations where needed.
(a) For what values of $x$ is $y = 1$?
(b) For what values of $x$ is $y = 3$?
(c) For what values of $y$ is $x = 3$?
(d) For what values of $x$ is $y \le 0$?
(e) What are the maximum and minimum values of $y$ and for what values of $x$ do they occur?



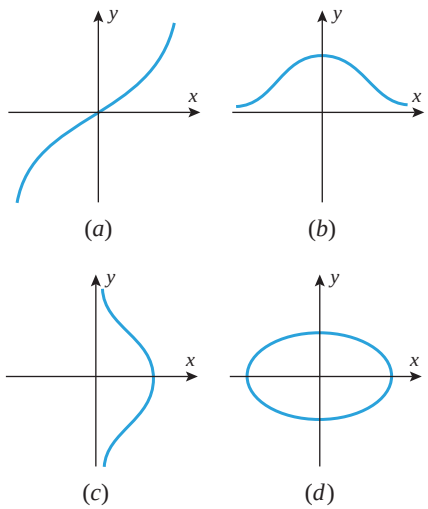
◀ **Figure Ex-1**

**2.** Use the accompanying table to answer the questions posed in Exercise 1.

| $x$ | −2 | −1 | 0 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|---|---|
| $y$ | 5 | 1 | −2 | 7 | −1 | 1 | 0 | 9 |

▲ **Table Ex-2**

**3.** In each part of the accompanying figure, determine whether the graph defines $y$ as a function of $x$.



▲ **Figure Ex-3**

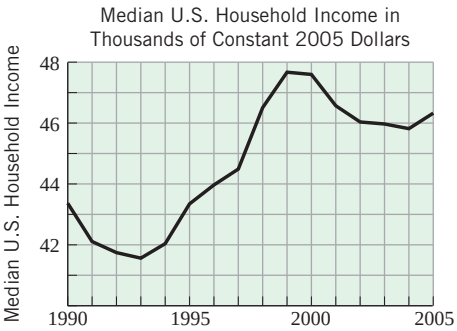
**4.** In each part, compare the natural domains of $f$ and $g$.

(a) $f(x) = \dfrac{x^2 + x}{x + 1}$; $g(x) = x$

(b) $f(x) = \dfrac{x\sqrt{x} + \sqrt{x}}{x + 1}$; $g(x) = \sqrt{x}$

**FOCUS ON CONCEPTS**

**5.** The accompanying graph shows the median income in U.S. households (adjusted for inflation) between 1990 and 2005. Use the graph to answer the following questions, making reasonable approximations where needed.
(a) When was the median income at its maximum value, and what was the median income when that occurred?
(b) When was the median income at its minimum value, and what was the median income when that occurred?
(c) The median income was declining during the 2-year period between 2000 and 2002. Was it declining more rapidly during the first year or the second year of that period? Explain your reasoning.



***Source:*** U.S. Census Bureau, August 2006.

▲ **Figure Ex-5**

**6.** Use the median income graph in Exercise 5 to answer the following questions, making reasonable approximations where needed.
(a) What was the average yearly growth of median income between 1993 and 1999?
(b) The median income was increasing during the 6-year period between 1993 and 1999. Was it increasing more rapidly during the first 3 years or the last 3 years of that period? Explain your reasoning.
(c) Consider the statement: "After years of decline, median income this year was finally higher than that of last year." In what years would this statement have been correct?

**7.** Find $f(0)$, $f(2)$, $f(-2)$, $f(3)$, $f(\sqrt{2})$, and $f(3t)$.

(a) $f(x) = 3x^2 - 2$ (b) $f(x) = \begin{cases} \dfrac{1}{x}, & x > 3 \\ 2x, & x \le 3 \end{cases}$

**8.** Find $g(3)$, $g(-1)$, $g(\pi)$, $g(-1.1)$, and $g(t^2 - 1)$.

(a) $g(x) = \dfrac{x+1}{x-1}$ (b) $g(x) = \begin{cases} \sqrt{x+1}, & x \ge 1 \\ 3, & x < 1 \end{cases}$

**9–10** Find the natural domain and determine the range of each function. If you have a graphing utility, use it to confirm that your result is consistent with the graph produced by your graphing utility. [*Note:* Set your graphing utility in radian mode when graphing trigonometric functions.]

**9.** (a) $f(x) = \dfrac{1}{x-3}$ (b) $F(x) = \dfrac{x}{|x|}$

(c) $g(x) = \sqrt{x^2 - 3}$ (d) $G(x) = \sqrt{x^2 - 2x + 5}$

(e) $h(x) = \dfrac{1}{1 - \sin x}$ (f) $H(x) = \sqrt{\dfrac{x^2 - 4}{x - 2}}$

**10.** (a) $f(x) = \sqrt{3 - x}$ (b) $F(x) = \sqrt{4 - x^2}$

(c) $g(x) = 3 + \sqrt{x}$ (d) $G(x) = x^3 + 2$

(e) $h(x) = 3 \sin x$ (f) $H(x) = (\sin \sqrt{x})^{-2}$

## FOCUS ON CONCEPTS

**11.** (a) If you had a device that could record the Earth's population continuously, would you expect the graph of population versus time to be a continuous (unbroken) curve? Explain what might cause breaks in the curve.

(b) Suppose that a hospital patient receives an injection of an antibiotic every 8 hours and that between injections the concentration $C$ of the antibiotic in the bloodstream decreases as the antibiotic is absorbed by the tissues. What might the graph of $C$ versus the elapsed time $t$ look like?

**12.** (a) If you had a device that could record the temperature of a room continuously over a 24-hour period, would you expect the graph of temperature versus time to be a continuous (unbroken) curve? Explain your reasoning.

(b) If you had a computer that could track the number of boxes of cereal on the shelf of a market continuously over a 1-week period, would you expect the graph of the number of boxes on the shelf versus time to be a continuous (unbroken) curve? Explain your reasoning.

**13.** A boat is bobbing up and down on some gentle waves. Suddenly it gets hit by a large wave and sinks. Sketch a rough graph of the height of the boat above the ocean floor as a function of time.

**14.** A cup of hot coffee sits on a table. You pour in some cool milk and let it sit for an hour. Sketch a rough graph of the temperature of the coffee as a function of time.

**15–18** As seen in Example 3, the equation $x^2 + y^2 = 25$ does not define $y$ as a function of $x$. Each graph in these exercises is a portion of the circle $x^2 + y^2 = 25$. In each case, determine whether the graph defines $y$ as a function of $x$, and if so, give a formula for $y$ in terms of $x$.

# 0.2 NEW FUNCTIONS FROM OLD

*Just as numbers can be added, subtracted, multiplied, and divided to produce other numbers, so functions can be added, subtracted, multiplied, and divided to produce other functions. In this section we will discuss these operations and some others that have no analogs in ordinary arithmetic.*

## ARITHMETIC OPERATIONS ON FUNCTIONS

Two functions, $f$ and $g$, can be added, subtracted, multiplied, and divided in a natural way to form new functions $f + g$, $f - g$, $fg$, and $f/g$. For example, $f + g$ is defined by the formula

$$(f + g)(x) = f(x) + g(x) \tag{1}$$

which states that for each input the value of $f + g$ is obtained by adding the values of $f$ and $g$. Equation (1) provides a formula for $f + g$ but does not say anything about the domain of $f + g$. However, for the right side of this equation to be defined, $x$ must lie in the domains of both $f$ and $g$, so we define the domain of $f + g$ to be the intersection of these two domains. More generally, we make the following definition.

**0.2.1 DEFINITION** Given functions $f$ and $g$, we define

$$(f+g)(x) = f(x) + g(x)$$
$$(f-g)(x) = f(x) - g(x)$$
$$(fg)(x) = f(x)g(x)$$
$$(f/g)(x) = f(x)/g(x)$$

For the functions $f+g$, $f-g$, and $fg$ we define the domain to be the intersection of the domains of $f$ and $g$, and for the function $f/g$ we define the domain to be the intersection of the domains of $f$ and $g$ but with the points where $g(x) = 0$ excluded (to avoid division by zero).

If $f$ is a constant function, that is, $f(x) = c$ for all $x$, then the product of $f$ and $g$ is $cg$, so multiplying a function by a constant is a special case of multiplying two functions.

▶ **Example 1** Let

$$f(x) = 1 + \sqrt{x-2} \quad \text{and} \quad g(x) = x - 3$$

Find the domains and formulas for the functions $f+g$, $f-g$, $fg$, $f/g$, and $7f$.

***Solution.*** First, we will find the formulas and then the domains. The formulas are

$$(f+g)(x) = f(x) + g(x) = (1 + \sqrt{x-2}\,) + (x-3) = x - 2 + \sqrt{x-2} \tag{2}$$
$$(f-g)(x) = f(x) - g(x) = (1 + \sqrt{x-2}\,) - (x-3) = 4 - x + \sqrt{x-2} \tag{3}$$
$$(fg)(x) = f(x)g(x) = (1 + \sqrt{x-2}\,)(x-3) \tag{4}$$
$$(f/g)(x) = f(x)/g(x) = \frac{1 + \sqrt{x-2}}{x-3} \tag{5}$$
$$(7f)(x) = 7f(x) = 7 + 7\sqrt{x-2} \tag{6}$$

The domains of $f$ and $g$ are $[2, +\infty)$ and $(-\infty, +\infty)$, respectively (their natural domains). Thus, it follows from Definition 0.2.1 that the domains of $f+g$, $f-g$, and $fg$ are the intersection of these two domains, namely,

$$[2, +\infty) \cap (-\infty, +\infty) = [2, +\infty) \tag{7}$$

Moreover, since $g(x) = 0$ if $x = 3$, the domain of $f/g$ is (7) with $x = 3$ removed, namely,

$$[2, 3) \cup (3, +\infty)$$

Finally, the domain of $7f$ is the same as the domain of $f$. ◀

We saw in the last example that the domains of the functions $f+g$, $f-g$, $fg$, and $f/g$ were the natural domains resulting from the formulas obtained for these functions. The following example shows that this will not always be the case.

▶ **Example 2** Show that if $f(x) = \sqrt{x}$, $g(x) = \sqrt{x}$, and $h(x) = x$, then the domain of $fg$ is not the same as the natural domain of $h$.

***Solution.*** The natural domain of $h(x) = x$ is $(-\infty, +\infty)$. Note that

$$(fg)(x) = \sqrt{x}\sqrt{x} = x = h(x)$$

on the domain of $fg$. The domains of both $f$ and $g$ are $[0, +\infty)$, so the domain of $fg$ is

$$[0, +\infty) \cap [0, +\infty) = [0, +\infty)$$

by Definition 0.2.1. Since the domains of $fg$ and $h$ are different, it would be misleading to write $(fg)(x) = x$ without including the restriction that this formula holds only for $x \geq 0$. ◀

## COMPOSITION OF FUNCTIONS

We now consider an operation on functions, called *composition*, which has no direct analog in ordinary arithmetic. Informally stated, the operation of composition is performed by substituting some function for the independent variable of another function. For example, suppose that

$$f(x) = x^2 \quad \text{and} \quad g(x) = x + 1$$

If we substitute $g(x)$ for $x$ in the formula for $f$, we obtain a new function

$$f(g(x)) = (g(x))^2 = (x + 1)^2$$

which we denote by $f \circ g$. Thus,

$$(f \circ g)(x) = f(g(x)) = (g(x))^2 = (x + 1)^2$$

In general, we make the following definition.

Although the domain of $f \circ g$ may seem complicated at first glance, it makes sense intuitively: To compute $f(g(x))$ one needs $x$ in the domain of $g$ to compute $g(x)$, and one needs $g(x)$ in the domain of $f$ to compute $f(g(x))$.

**0.2.2 DEFINITION** Given functions $f$ and $g$, the ***composition*** of $f$ with $g$, denoted by $f \circ g$, is the function defined by

$$(f \circ g)(x) = f(g(x))$$

The domain of $f \circ g$ is defined to consist of all $x$ in the domain of $g$ for which $g(x)$ is in the domain of $f$.

▶ **Example 3** Let $f(x) = x^2 + 3$ and $g(x) = \sqrt{x}$. Find

(a) $(f \circ g)(x)$ (b) $(g \circ f)(x)$

***Solution (a).*** The formula for $f(g(x))$ is

$$f(g(x)) = [g(x)]^2 + 3 = (\sqrt{x}\,)^2 + 3 = x + 3$$

Since the domain of $g$ is $[0, +\infty)$ and the domain of $f$ is $(-\infty, +\infty)$, the domain of $f \circ g$ consists of all $x$ in $[0, +\infty)$ such that $g(x) = \sqrt{x}$ lies in $(-\infty, +\infty)$; thus, the domain of $f \circ g$ is $[0, +\infty)$. Therefore,

$$(f \circ g)(x) = x + 3, \quad x \geq 0$$

***Solution (b).*** The formula for $g(f(x))$ is

$$g(f(x)) = \sqrt{f(x)} = \sqrt{x^2 + 3}$$

Since the domain of $f$ is $(-\infty, +\infty)$ and the domain of $g$ is $[0, +\infty)$, the domain of $g \circ f$ consists of all $x$ in $(-\infty, +\infty)$ such that $f(x) = x^2 + 3$ lies in $[0, +\infty)$. Thus, the domain of $g \circ f$ is $(-\infty, +\infty)$. Therefore,

$$(g \circ f)(x) = \sqrt{x^2 + 3}$$

There is no need to indicate that the domain is $(-\infty, +\infty)$, since this is the natural domain of $\sqrt{x^2 + 3}$. ◀

Note that the functions $f \circ g$ and $g \circ f$ in Example 3 are not the same. Thus, the order in which functions are composed can (and usually will) make a difference in the end result.

Compositions can also be defined for three or more functions; for example, $(f \circ g \circ h)(x)$ is computed as

$$(f \circ g \circ h)(x) = f(g(h(x)))$$

In other words, first find $h(x)$, then find $g(h(x))$, and then find $f(g(h(x)))$.

**▶ Example 4** Find $(f \circ g \circ h)(x)$ if

$$f(x) = \sqrt{x}, \quad g(x) = 1/x, \quad h(x) = x^3$$

***Solution.***

$$(f \circ g \circ h)(x) = f(g(h(x))) = f(g(x^3)) = f(1/x^3) = \sqrt{1/x^3} = 1/x^{3/2} \quad \blacktriangleleft$$

## EXPRESSING A FUNCTION AS A COMPOSITION

Many problems in mathematics are solved by "decomposing" functions into compositions of simpler functions. For example, consider the function $h$ given by

$$h(x) = (x + 1)^2$$

To evaluate $h(x)$ for a given value of $x$, we would first compute $x + 1$ and then square the result. These two operations are performed by the functions

$$g(x) = x + 1 \quad \text{and} \quad f(x) = x^2$$

We can express $h$ in terms of $f$ and $g$ by writing

$$h(x) = (x + 1)^2 = [g(x)]^2 = f(g(x))$$

so we have succeeded in expressing $h$ as the composition $h = f \circ g$.

The thought process in this example suggests a general procedure for decomposing a function $h$ into a composition $h = f \circ g$:

- Think about how you would evaluate $h(x)$ for a specific value of $x$, trying to break the evaluation into two steps performed in succession.
- The first operation in the evaluation will determine a function $g$ and the second a function $f$.
- The formula for $h$ can then be written as $h(x) = f(g(x))$.

For descriptive purposes, we will refer to $g$ as the "inside function" and $f$ as the "outside function" in the expression $f(g(x))$. The inside function performs the first operation and the outside function performs the second.

**▶ Example 5** Express $\sin(x^3)$ as a composition of two functions.

***Solution.*** To evaluate $\sin(x^3)$, we would first compute $x^3$ and then take the sine, so $g(x) = x^3$ is the inside function and $f(x) = \sin x$ the outside function. Therefore,

$$\sin(x^3) = f(g(x)) \qquad \boxed{g(x) = x^3 \text{ and } f(x) = \sin x} \quad \blacktriangleleft$$

Table 0.2.1 gives some more examples of decomposing functions into compositions.

**Table 0.2.1**
COMPOSING FUNCTIONS

| FUNCTION | $g(x)$ INSIDE | $f(x)$ OUTSIDE | COMPOSITION |
|---|---|---|---|
| $(x^2+1)^{10}$ | $x^2+1$ | $x^{10}$ | $(x^2+1)^{10} = f(g(x))$ |
| $\sin^3 x$ | $\sin x$ | $x^3$ | $\sin^3 x = f(g(x))$ |
| $\tan(x^5)$ | $x^5$ | $\tan x$ | $\tan(x^5) = f(g(x))$ |
| $\sqrt{4-3x}$ | $4-3x$ | $\sqrt{x}$ | $\sqrt{4-3x} = f(g(x))$ |
| $8+\sqrt{x}$ | $\sqrt{x}$ | $8+x$ | $8+\sqrt{x} = f(g(x))$ |
| $\dfrac{1}{x+1}$ | $x+1$ | $\dfrac{1}{x}$ | $\dfrac{1}{x+1} = f(g(x))$ |

**REMARK** There is always more than one way to express a function as a composition. For example, here are two ways to express $(x^2+1)^{10}$ as a composition that differ from that in Table 0.2.1:

$$(x^2+1)^{10} = [(x^2+1)^2]^5 = f(g(x)) \qquad g(x) = (x^2+1)^2 \text{ and } f(x) = x^5$$

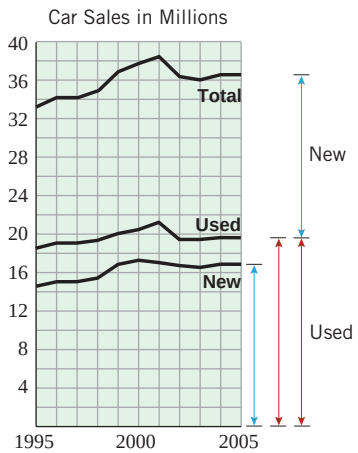
$$(x^2+1)^{10} = [(x^2+1)^3]^{10/3} = f(g(x)) \qquad g(x) = (x^2+1)^3 \text{ and } f(x) = x^{10/3}$$

## NEW FUNCTIONS FROM OLD

The remainder of this section will be devoted to considering the geometric effect of performing basic operations on functions. This will enable us to use known graphs of functions to visualize or sketch graphs of related functions. For example, Figure 0.2.1 shows the graphs of yearly new car sales $N(t)$ and used car sales $U(t)$ over a certain time period. Those graphs can be used to construct the graph of the total car sales

$$T(t) = N(t) + U(t)$$

by adding the values of $N(t)$ and $U(t)$ for each value of $t$. In general, the graph of $y = f(x) + g(x)$ can be constructed from the graphs of $y = f(x)$ and $y = g(x)$ by adding corresponding $y$-values for each $x$.



***Source:*** NADA.

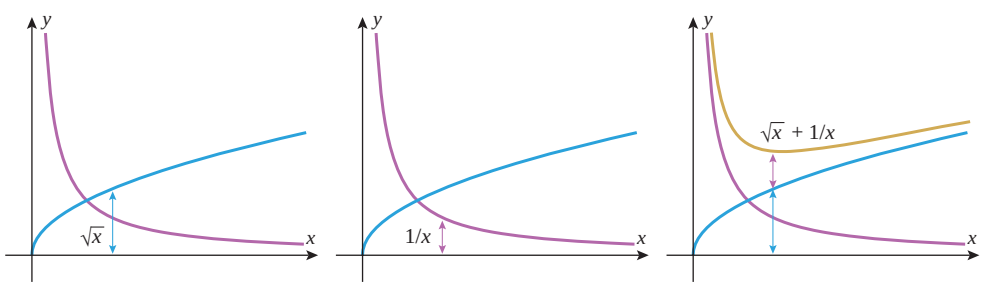
▲ **Figure 0.2.1**

▶ **Example 6** Referring to Figure 0.1.4 for the graphs of $y = \sqrt{x}$ and $y = 1/x$, make a sketch that shows the general shape of the graph of $y = \sqrt{x} + 1/x$ for $x \geq 0$.

***Solution.*** To add the corresponding $y$-values of $y = \sqrt{x}$ and $y = 1/x$ graphically, just imagine them to be "stacked" on top of one another. This yields the sketch in Figure 0.2.2. ◀

Use the technique in Example 6 to sketch the graph of the function

$$\sqrt{x} - \frac{1}{x}$$



▶ **Figure 0.2.2**

Add the $y$-coordinates of $\sqrt{x}$ and $1/x$ to obtain the $y$-coordinate of $\sqrt{x} + 1/x$.

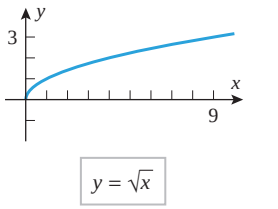
## TRANSLATIONS

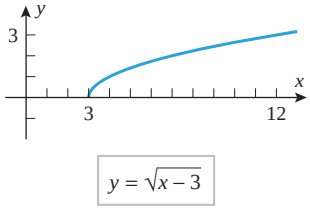
Table 0.2.2 illustrates the geometric effect on the graph of $y = f(x)$ of adding or subtracting a *positive* constant $c$ to $f$ or to its independent variable $x$. For example, the first result in the table illustrates that adding a positive constant $c$ to a function $f$ adds $c$ to each $y$-coordinate of its graph, thereby shifting the graph of $f$ up by $c$ units. Similarly, subtracting $c$ from $f$ shifts the graph down by $c$ units. On the other hand, if a positive constant $c$ is added to $x$, then the value of $y = f(x + c)$ at $x - c$ is $f(x)$; and since the point $x - c$ is $c$ units to the left of $x$ on the $x$-axis, the graph of $y = f(x + c)$ must be the graph of $y = f(x)$ shifted left by $c$ units. Similarly, subtracting $c$ from $x$ shifts the graph of $y = f(x)$ right by $c$ units.

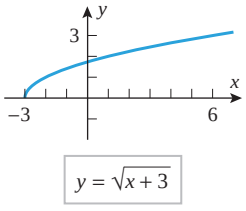
**Table 0.2.2**

TRANSLATION PRINCIPLES

| OPERATION ON $y = f(x)$ | Add a positive constant $c$ to $f(x)$ | Subtract a positive constant $c$ from $f(x)$ | Add a positive constant $c$ to $x$ | Subtract a positive constant $c$ from $x$ |
|---|---|---|---|---|
| NEW EQUATION | $y = f(x) + c$ | $y = f(x) - c$ | $y = f(x + c)$ | $y = f(x - c)$ |
| GEOMETRIC EFFECT | Translates the graph of $y = f(x)$ up $c$ units | Translates the graph of $y = f(x)$ down $c$ units | Translates the graph of $y = f(x)$ left $c$ units | Translates the graph of $y = f(x)$ right $c$ units |
| EXAMPLE |   |   |   |   |







▲ Figure 0.2.3

Before proceeding to the next examples, it will be helpful to review the graphs in Figures 0.1.4 and 0.1.9.

**▶ Example 7** Sketch the graph of

$$\text{(a) } y = \sqrt{x - 3} \qquad \text{(b) } y = \sqrt{x + 3}$$

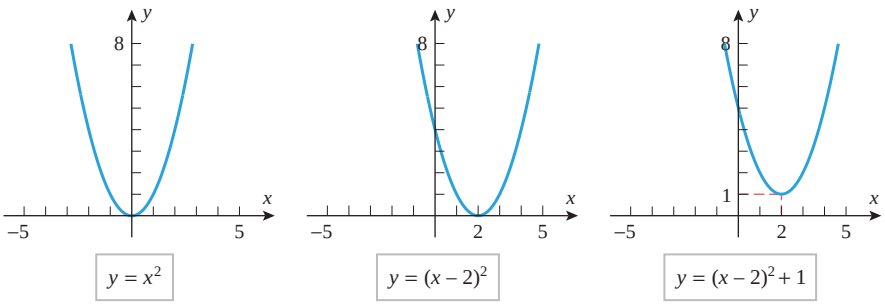
***Solution.*** Using the translation principles given in Table 0.2.2, the graph of the equation $y = \sqrt{x - 3}$ can be obtained by translating the graph of $y = \sqrt{x}$ right 3 units. The graph of $y = \sqrt{x + 3}$ can be obtained by translating the graph of $y = \sqrt{x}$ left 3 units (Figure 0.2.3). ◀

**▶ Example 8** Sketch the graph of $y = x^2 - 4x + 5$.

***Solution.*** Completing the square on the first two terms yields

$$y = (x^2 - 4x + 4) - 4 + 5 = (x - 2)^2 + 1$$

(see Web Appendix H for a review of this technique). In this form we see that the graph can be obtained by translating the graph of $y = x^2$ right 2 units because of the $x - 2$, and up 1 unit because of the $+1$ (Figure 0.2.4). ◀



▶ Figure 0.2.4

## REFLECTIONS

The graph of $y = f(-x)$ is the reflection of the graph of $y = f(x)$ about the $y$-axis because the point $(x, y)$ on the graph of $f(x)$ is replaced by $(-x, y)$. Similarly, the graph of $y = -f(x)$ is the reflection of the graph of $y = f(x)$ about the $x$-axis because the point $(x, y)$ on the graph of $f(x)$ is replaced by $(x, -y)$ [the equation $y = -f(x)$ is equivalent to $-y = f(x)$]. This is summarized in Table 0.2.3.

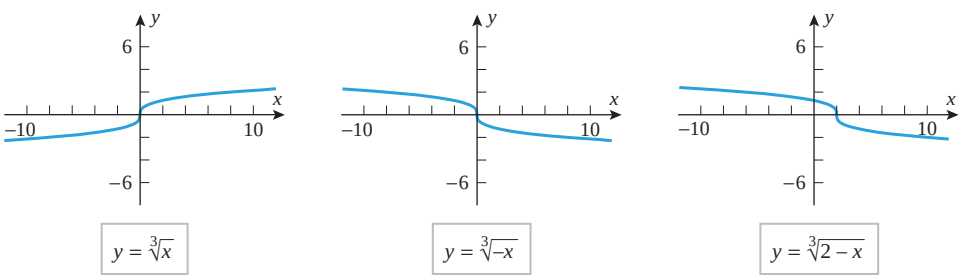
**Table 0.2.3**

REFLECTION PRINCIPLES

| OPERATION ON $y = f(x)$ | Replace $x$ by $-x$ | Multiply $f(x)$ by $-1$ |
|---|---|---|
| NEW EQUATION | $y = f(-x)$ | $y = -f(x)$ |
| GEOMETRIC EFFECT | Reflects the graph of $y = f(x)$ about the $y$-axis | Reflects the graph of $y = f(x)$ about the $x$-axis |
| EXAMPLE |  |  |

▶ **Example 9** Sketch the graph of $y = \sqrt[3]{2 - x}$.

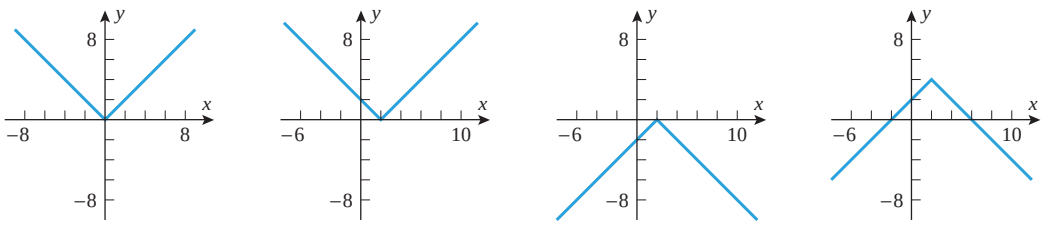
***Solution.*** Using the translation and reflection principles in Tables 0.2.2 and 0.2.3, we can obtain the graph by a reflection followed by a translation as follows: First reflect the graph of $y = \sqrt[3]{x}$ about the $y$-axis to obtain the graph of $y = \sqrt[3]{-x}$, then translate this graph right 2 units to obtain the graph of the equation $y = \sqrt[3]{-(x - 2)} = \sqrt[3]{2 - x}$ (Figure 0.2.5). ◀



▶ Figure 0.2.5

▶ **Example 10** Sketch the graph of $y = 4 - |x - 2|$.

***Solution.*** The graph can be obtained by a reflection and two translations: First translate the graph of $y = |x|$ right 2 units to obtain the graph of $y = |x - 2|$; then reflect this graph about the $x$-axis to obtain the graph of $y = -|x - 2|$; and then translate this graph up 4 units to obtain the graph of the equation $y = -|x - 2| + 4 = 4 - |x - 2|$ (Figure 0.2.6). ◀



▲ **Figure 0.2.6**

## STRETCHES AND COMPRESSIONS

Multiplying $f(x)$ by a *positive* constant $c$ has the geometric effect of stretching the graph of $y = f(x)$ in the $y$-direction by a factor of $c$ if $c > 1$ and compressing it in the $y$-direction by a factor of $1/c$ if $0 < c < 1$. For example, multiplying $f(x)$ by 2 doubles each $y$-coordinate, thereby stretching the graph vertically by a factor of 2, and multiplying by $\frac{1}{2}$ cuts each $y$-coordinate in half, thereby compressing the graph vertically by a factor of 2. Similarly, multiplying $x$ by a *positive* constant $c$ has the geometric effect of compressing the graph of $y = f(x)$ by a factor of $c$ in the $x$-direction if $c > 1$ and stretching it by a factor of $1/c$ if $0 < c < 1$. [If this seems backwards to you, then think of it this way: The value of $2x$ changes twice as fast as $x$, so a point moving along the $x$-axis from the origin will only have to move half as far for $y = f(2x)$ to have the same value as $y = f(x)$, thereby creating a horizontal compression of the graph.] All of this is summarized in Table 0.2.4.

Describe the geometric effect of multiplying a function $f$ by a *negative* constant in terms of reflection and stretching or compressing. What is the geometric effect of multiplying the independent variable of a function $f$ by a *negative* constant?

**Table 0.2.4**

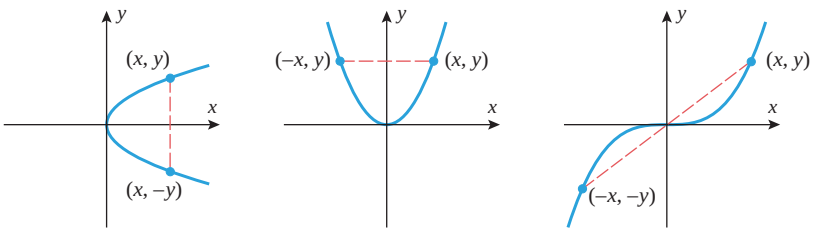
STRETCHING AND COMPRESSING PRINCIPLES

| OPERATION ON $y = f(x)$ | Multiply $f(x)$ by $c$ $(c > 1)$ | Multiply $f(x)$ by $c$ $(0 < c < 1)$ | Multiply $x$ by $c$ $(c > 1)$ | Multiply $x$ by $c$ $(0 < c < 1)$ |
|---|---|---|---|---|
| NEW EQUATION | $y = cf(x)$ | $y = cf(x)$ | $y = f(cx)$ | $y = f(cx)$ |
| GEOMETRIC EFFECT | Stretches the graph of $y = f(x)$ vertically by a factor of $c$ | Compresses the graph of $y = f(x)$ vertically by a factor of $1/c$ | Compresses the graph of $y = f(x)$ horizontally by a factor of $c$ | Stretches the graph of $y = f(x)$ horizontally by a factor of $1/c$ |
| EXAMPLE |   |   |   |   |

## SYMMETRY

Figure 0.2.7 illustrates three types of symmetries: ***symmetry about the x-axis***, ***symmetry about the y-axis***, and ***symmetry about the origin***. As illustrated in the figure, a curve is symmetric about the $x$-axis if for each point $(x, y)$ on the graph the point $(x, -y)$ is also on the graph, and it is symmetric about the $y$-axis if for each point $(x, y)$ on the graph the point $(-x, y)$ is also on the graph. A curve is symmetric about the origin if for each point $(x, y)$ on the graph, the point $(-x, -y)$ is also on the graph. (Equivalently, a graph is symmetric about the origin if rotating the graph 180° about the origin leaves it unchanged.) This suggests the following symmetry tests.

Explain why the graph of a nonzero function cannot be symmetric about the $x$-axis.



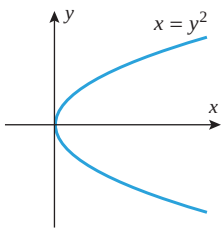
▶ Figure 0.2.7

**0.2.3 THEOREM (*Symmetry Tests*)**

(*a*) *A plane curve is symmetric about the y-axis if and only if replacing $x$ by $-x$ in its equation produces an equivalent equation.*

(*b*) *A plane curve is symmetric about the x-axis if and only if replacing $y$ by $-y$ in its equation produces an equivalent equation.*

(*c*) *A plane curve is symmetric about the origin if and only if replacing both $x$ by $-x$ and $y$ by $-y$ in its equation produces an equivalent equation.*



▲ Figure 0.2.8

▶ **Example 11** Use Theorem 0.2.3 to identify symmetries in the graph of $x = y^2$.

***Solution.*** Replacing $y$ by $-y$ yields $x = (-y)^2$, which simplifies to the original equation $x = y^2$. Thus, the graph is symmetric about the $x$-axis. The graph is not symmetric about the $y$-axis because replacing $x$ by $-x$ yields $-x = y^2$, which is not equivalent to the original equation $x = y^2$. Similarly, the graph is not symmetric about the origin because replacing $x$ by $-x$ and $y$ by $-y$ yields $-x = (-y)^2$, which simplifies to $-x = y^2$, and this is again not equivalent to the original equation. These results are consistent with the graph of $x = y^2$ shown in Figure 0.2.8. ◀

## EVEN AND ODD FUNCTIONS

A function $f$ is said to be an ***even function*** if

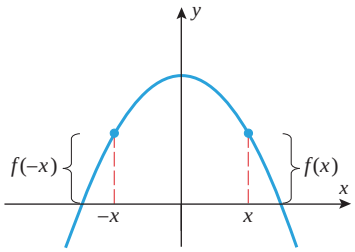
$$f(-x) = f(x) \tag{8}$$

and is said to be an ***odd function*** if

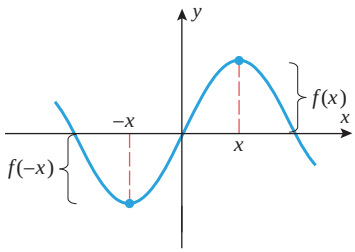
$$f(-x) = -f(x) \tag{9}$$

Geometrically, the graphs of even functions are symmetric about the $y$-axis because replacing $x$ by $-x$ in the equation $y = f(x)$ yields $y = f(-x)$, which is equivalent to the original

equation $y = f(x)$ by (8) (see Figure 0.2.9). Similarly, it follows from (9) that graphs of odd functions are symmetric about the origin (see Figure 0.2.10). Some examples of even functions are $x^2$, $x^4$, $x^6$, and $\cos x$; and some examples of odd functions are $x^3$, $x^5$, $x^7$, and $\sin x$.



▲ **Figure 0.2.9** This is the graph of an even function since $f(-x) = f(x)$.



▲ **Figure 0.2.10** This is the graph of an odd function since $f(-x) = -f(x)$.

## ✔ QUICK CHECK EXERCISES 0.2 *(See page 27 for answers.)*

**1.** Let $f(x) = 3\sqrt{x} - 2$ and $g(x) = |x|$. In each part, give the formula for the function and state the corresponding domain.
(a) $f + g$: _____ Domain: _____
(b) $f - g$: _____ Domain: _____
(c) $fg$: _____ Domain: _____
(d) $f/g$: _____ Domain: _____

**2.** Let $f(x) = 2 - x^2$ and $g(x) = \sqrt{x}$. In each part, give the formula for the composition and state the corresponding domain.
(a) $f \circ g$: _____ Domain: _____
(b) $g \circ f$: _____ Domain: _____

**3.** The graph of $y = 1 + (x - 2)^2$ may be obtained by shifting the graph of $y = x^2$ _____ (left/right) by _____ unit(s) and then shifting this new graph _____ (up/down) by _____ unit(s).

**4.** Let

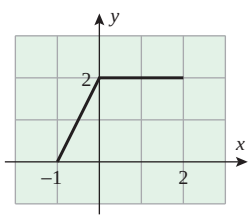
$$f(x) = \begin{cases} |x + 1|, & -2 \le x \le 0 \\ |x - 1|, & 0 < x \le 2 \end{cases}$$

(a) The letter of the alphabet that most resembles the graph of $f$ is _____.
(b) Is $f$ an even function?

## EXERCISE SET 0.2 Graphing Utility

### FOCUS ON CONCEPTS

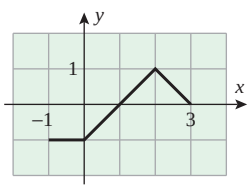
**1.** The graph of a function $f$ is shown in the accompanying figure. Sketch the graphs of the following equations.
(a) $y = f(x) - 1$ (b) $y = f(x - 1)$
(c) $y = \frac{1}{2} f(x)$ (d) $y = f\left(-\frac{1}{2}x\right)$



◀ **Figure Ex-1**

**2.** Use the graph in Exercise 1 to sketch the graphs of the following equations.
(a) $y = -f(-x)$ (b) $y = f(2 - x)$
(c) $y = 1 - f(2 - x)$ (d) $y = \frac{1}{2} f(2x)$

**3.** The graph of a function $f$ is shown in the accompanying figure. Sketch the graphs of the following equations.
(a) $y = f(x + 1)$ (b) $y = f(2x)$
(c) $y = |f(x)|$ (d) $y = 1 - |f(x)|$



◀ **Figure Ex-3**

**4.** Use the graph in Exercise 3 to sketch the graph of the equation $y = f(|x|)$.

**5–24** Sketch the graph of the equation by translating, reflecting, compressing, and stretching the graph of $y = x^2$, $y = \sqrt{x}$, $y = 1/x$, $y = |x|$, or $y = \sqrt[3]{x}$ appropriately. Then use a graphing utility to confirm that your sketch is correct. ■

**5.** $y = -2(x+1)^2 - 3$ **6.** $y = \frac{1}{2}(x-3)^2 + 2$

**7.** $y = x^2 + 6x$ **8.** $y = \frac{1}{2}(x^2 - 2x + 3)$

**9.** $y = 3 - \sqrt{x+1}$ **10.** $y = 1 + \sqrt{x-4}$

**11.** $y = \frac{1}{2}\sqrt{x} + 1$ **12.** $y = -\sqrt{3x}$

**13.** $y = \dfrac{1}{x-3}$ **14.** $y = \dfrac{1}{1-x}$

**15.** $y = 2 - \dfrac{1}{x+1}$ **16.** $y = \dfrac{x-1}{x}$

**17.** $y = |x+2| - 2$ **18.** $y = 1 - |x-3|$

**19.** $y = |2x-1| + 1$ **20.** $y = \sqrt{x^2 - 4x + 4}$

**21.** $y = 1 - 2\sqrt[3]{x}$ **22.** $y = \sqrt[3]{x-2} - 3$

**23.** $y = 2 + \sqrt[3]{x+1}$ **24.** $y + \sqrt[3]{x-2} = 0$

**25.** (a) Sketch the graph of $y = x + |x|$ by adding the corresponding $y$-coordinates on the graphs of $y = x$ and $y = |x|$.

(b) Express the equation $y = x + |x|$ in piecewise form with no absolute values, and confirm that the graph you obtained in part (a) is consistent with this equation.

**26.** Sketch the graph of $y = x + (1/x)$ by adding corresponding $y$-coordinates on the graphs of $y = x$ and $y = 1/x$. Use a graphing utility to confirm that your sketch is correct.

**27–28** Find formulas for $f+g$, $f-g$, $fg$, and $f/g$, and state the domains of the functions.

**27.** $f(x) = 2\sqrt{x-1}$, $g(x) = \sqrt{x-1}$

**28.** $f(x) = \dfrac{x}{1+x^2}$, $g(x) = \dfrac{1}{x}$

**29.** Let $f(x) = \sqrt{x}$ and $g(x) = x^3 + 1$. Find

(a) $f(g(2))$ (b) $g(f(4))$ (c) $f(f(16))$

(d) $g(g(0))$ (e) $f(2+h)$ (f) $g(3+h)$.

**30.** Let $g(x) = \sqrt{x}$. Find

(a) $g(5s+2)$ (b) $g(\sqrt{x}+2)$ (c) $3g(5x)$

(d) $\dfrac{1}{g(x)}$ (e) $g(g(x))$ (f) $(g(x))^2 - g(x^2)$

(g) $g(1/\sqrt{x}\,)$ (h) $g((x-1)^2)$ (i) $g(x+h)$.

**31–34** Find formulas for $f \circ g$ and $g \circ f$, and state the domains of the compositions.

**31.** $f(x) = x^2$, $g(x) = \sqrt{1-x}$

**32.** $f(x) = \sqrt{x-3}$, $g(x) = \sqrt{x^2+3}$

**33.** $f(x) = \dfrac{1+x}{1-x}$, $g(x) = \dfrac{x}{1-x}$

**34.** $f(x) = \dfrac{x}{1+x^2}$, $g(x) = \dfrac{1}{x}$

**35–36** Find a formula for $f \circ g \circ h$.

**35.** $f(x) = x^2 + 1$, $g(x) = \dfrac{1}{x}$, $h(x) = x^3$

**36.** $f(x) = \dfrac{1}{1+x}$, $g(x) = \sqrt[3]{x}$, $h(x) = \dfrac{1}{x^3}$

**37–42** Express $f$ as a composition of two functions; that is, find $g$ and $h$ such that $f = g \circ h$. [*Note:* Each exercise has more than one solution.]

**37.** (a) $f(x) = \sqrt{x+2}$ (b) $f(x) = |x^2 - 3x + 5|$

**38.** (a) $f(x) = x^2 + 1$ (b) $f(x) = \dfrac{1}{x-3}$

**39.** (a) $f(x) = \sin^2 x$ (b) $f(x) = \dfrac{3}{5 + \cos x}$

**40.** (a) $f(x) = 3\sin(x^2)$ (b) $f(x) = 3\sin^2 x + 4\sin x$

**41.** (a) $f(x) = \big(1 + \sin(x^2)\big)^3$ (b) $f(x) = \sqrt{1 - \sqrt[3]{x}}$

**42.** (a) $f(x) = \dfrac{1}{1-x^2}$ (b) $f(x) = |5 + 2x|$

**43–46 True–False** Determine whether the statement is true or false. Explain your answer.

**43.** The domain of $f+g$ is the intersection of the domains of $f$ and $g$.

**44.** The domain of $f \circ g$ consists of all values of $x$ in the domain of $g$ for which $g(x) \neq 0$.

**45.** The graph of an even function is symmetric about the $y$-axis.

**46.** The graph of $y = f(x+2) + 3$ is obtained by translating the graph of $y = f(x)$ right 2 units and up 3 units.

## FOCUS ON CONCEPTS

**47.** Use the data in the accompanying table to make a plot of $y = f(g(x))$.

| $x$ | −3 | −2 | −1 | 0 | 1 | 2 | 3 |
|---|---|---|---|---|---|---|---|

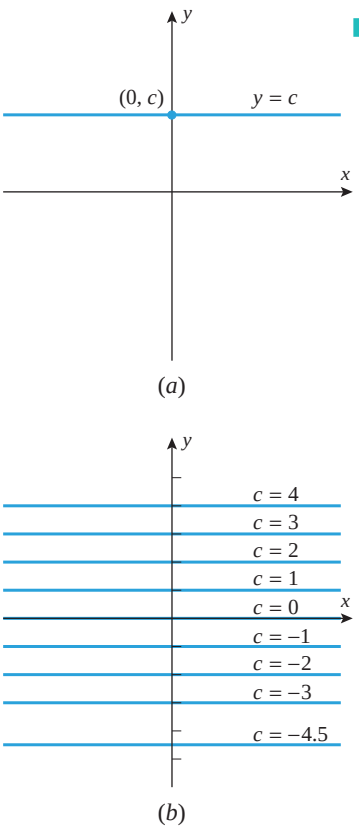
# 0.3 FAMILIES OF FUNCTIONS

*Functions are often grouped into families according to the form of their defining formulas or other common characteristics. In this section we will discuss some of the most basic families of functions.*

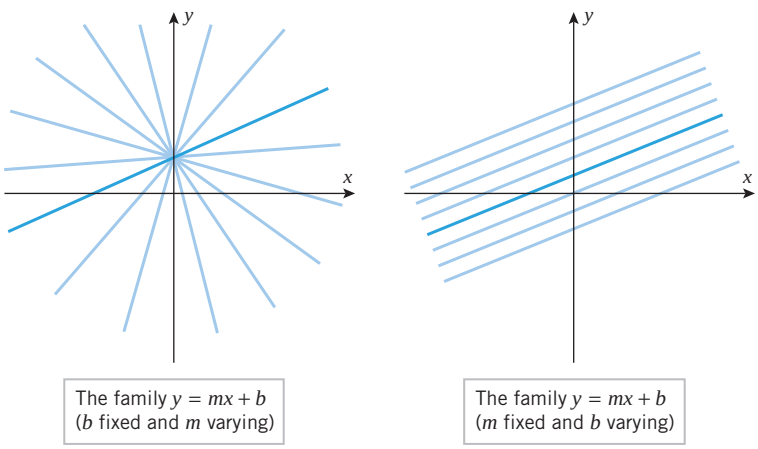
## FAMILIES OF CURVES

The graph of a constant function $f(x) = c$ is the graph of the equation $y = c$, which is the horizontal line shown in Figure 0.3.1*a*. If we vary $c$, then we obtain a set or ***family*** of horizontal lines such as those in Figure 0.3.1*b*.

Constants that are varied to produce families of curves are called ***parameters***. For example, recall that an equation of the form $y = mx + b$ represents a line of slope $m$ and $y$-intercept $b$. If we keep $b$ fixed and treat $m$ as a parameter, then we obtain a family of lines whose members all have $y$-intercept $b$ (Figure 0.3.2*a*), and if we keep $m$ fixed and treat $b$ as a parameter, we obtain a family of parallel lines whose members all have slope $m$ (Figure 0.3.2*b*).



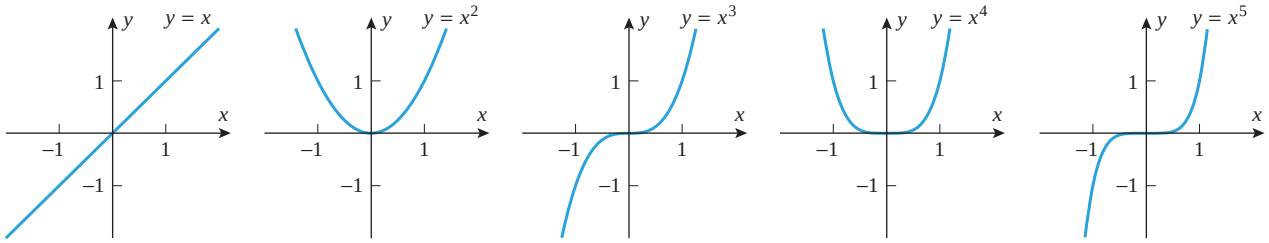
▲ **Figure 0.3.1**



▶ **Figure 0.3.2**

## POWER FUNCTIONS; THE FAMILY $y = x^n$

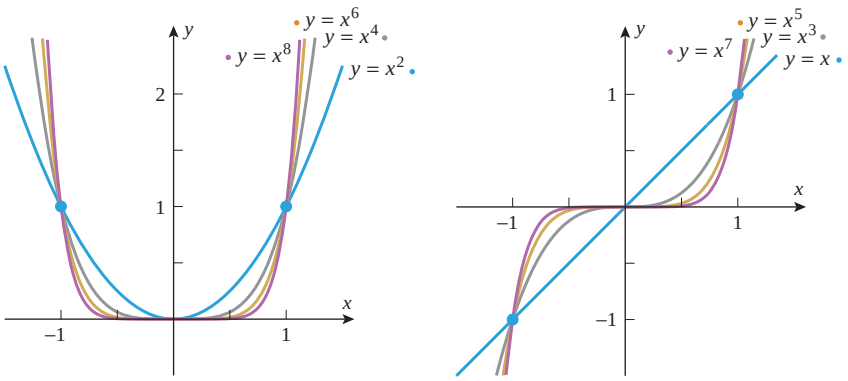
A function of the form $f(x) = x^p$, where $p$ is constant, is called a ***power function***. For the moment, let us consider the case where $p$ is a positive integer, say $p = n$. The graphs of the curves $y = x^n$ for $n = 1, 2, 3, 4$, and 5 are shown in Figure 0.3.3. The first graph is the line with slope 1 that passes through the origin, and the second is a parabola that opens up and has its vertex at the origin (see Web Appendix H).



▲ **Figure 0.3.3**

For $n \geq 2$ the shape of the curve $y = x^n$ depends on whether $n$ is even or odd (Figure 0.3.4):

- For even values of $n$, the functions $f(x) = x^n$ are even, so their graphs are symmetric about the $y$-axis. The graphs all have the general shape of the graph of $y = x^2$, and each graph passes through the points $(-1, 1)$, $(0, 0)$, and $(1, 1)$. As $n$ increases, the graphs become flatter over the interval $-1 < x < 1$ and steeper over the intervals $x > 1$ and $x < -1$.
- For odd values of $n$, the functions $f(x) = x^n$ are odd, so their graphs are symmetric about the origin. The graphs all have the general shape of the curve $y = x^3$, and each graph passes through the points $(-1, -1)$, $(0, 0)$, and $(1, 1)$. As $n$ increases, the graphs become flatter over the interval $-1 < x < 1$ and steeper over the intervals $x > 1$ and $x < -1$.



▶ **Figure 0.3.4**

**REMARK** The flattening and steepening effects can be understood by considering what happens when a number $x$ is raised to higher and higher powers: If $-1 < x < 1$, then the absolute value of $x^n$ *decreases* as $n$ increases, thereby causing the graphs to become flatter on this interval as $n$ increases (try raising $\frac{1}{2}$ or $-\frac{1}{2}$ to higher and higher powers). On the other hand, if $x > 1$ or $x < -1$, then the absolute value of $x^n$ *increases* as $n$ increases, thereby causing the graphs to become steeper on these intervals as $n$ increases (try raising 2 or $-2$ to higher and higher powers).

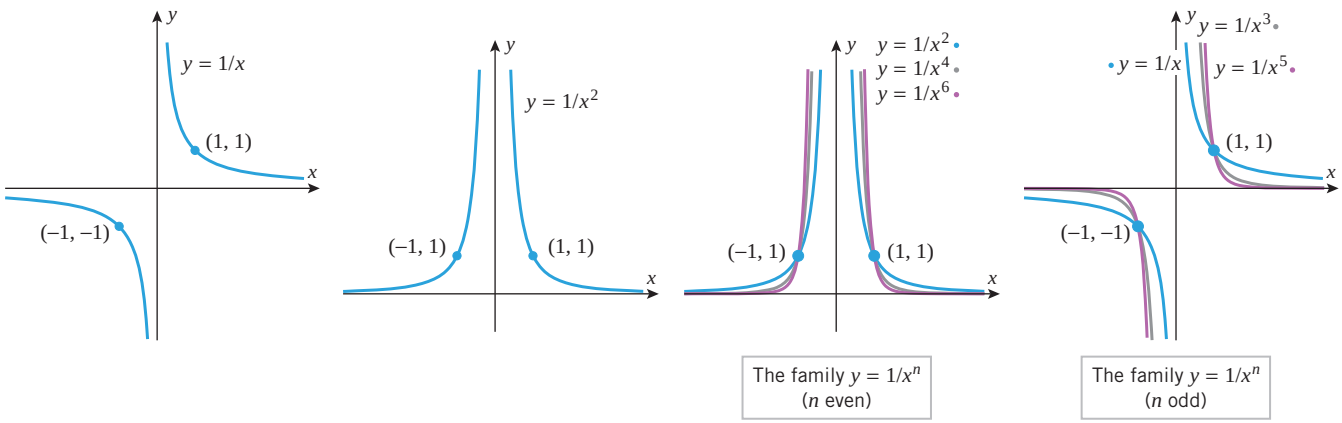
## THE FAMILY $y = x^{-n}$

If $p$ is a negative integer, say $p = -n$, then the power functions $f(x) = x^p$ have the form $f(x) = x^{-n} = 1/x^n$. Figure 0.3.5 shows the graphs of $y = 1/x$ and $y = 1/x^2$. The graph of $y = 1/x$ is called an ***equilateral hyperbola*** (for reasons to be discussed later).

As illustrated in Figure 0.3.5, the shape of the curve $y = 1/x^n$ depends on whether $n$ is even or odd:

- For even values of $n$, the functions $f(x) = 1/x^n$ are even, so their graphs are symmetric about the $y$-axis. The graphs all have the general shape of the curve $y = 1/x^2$, and each graph passes through the points $(-1, 1)$ and $(1, 1)$. As $n$ increases, the graphs become steeper over the intervals $-1 < x < 0$ and $0 < x < 1$ and become flatter over the intervals $x > 1$ and $x < -1$.
- For odd values of $n$, the functions $f(x) = 1/x^n$ are odd, so their graphs are symmetric about the origin. The graphs all have the general shape of the curve $y = 1/x$, and each graph passes through the points $(1, 1)$ and $(-1, -1)$. As $n$ increases, the graphs become steeper over the intervals $-1 < x < 0$ and $0 < x < 1$ and become flatter over the intervals $x > 1$ and $x < -1$.
- For both even and odd values of $n$ the graph $y = 1/x^n$ has a break at the origin (called a ***discontinuity***), which occurs because division by zero is undefined.

By considering the value of $1/x^n$ for a fixed $x$ as $n$ increases, explain why the graphs become flatter or steeper as described here for increasing values of $n$.



▲ **Figure 0.3.5**

## INVERSE PROPORTIONS

Recall that a variable $y$ is said to be ***inversely proportional to a variable x*** if there is a positive constant $k$, called the ***constant of proportionality***, such that

$$y = \frac{k}{x} \tag{1}$$

Since $k$ is assumed to be positive, the graph of (1) has the same shape as $y = 1/x$ but is compressed or stretched in the $y$-direction. Also, it should be evident from (1) that doubling $x$ multiplies $y$ by $\frac{1}{2}$, tripling $x$ multiplies $y$ by $\frac{1}{3}$, and so forth.

Equation (1) can be expressed as $xy = k$, which tells us that the product of inversely proportional variables is a positive constant. This is a useful form for identifying inverse proportionality in experimental data.

**Table 0.3.1**

| $x$ | 0.8 | 1 | 2.5 | 4 | 6.25 | 10 |
|---|---|---|---|---|---|---|
| $y$ | 6.25 | 5 | 2 | 1.25 | 0.8 | 0.5 |

▶ **Example 1** Table 0.3.1 shows some experimental data.

(a) Explain why the data suggest that $y$ is inversely proportional to $x$.

(b) Express $y$ as a function of $x$.

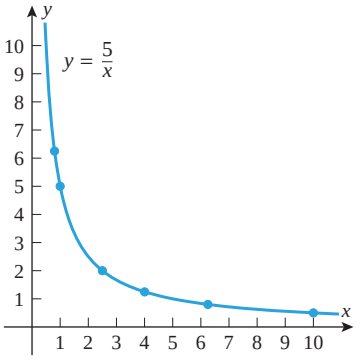
(c) Graph your function and the data together for $x > 0$.

***Solution.*** For every data point we have $xy = 5$, so $y$ is inversely proportional to $x$ and $y = 5/x$. The graph of this equation with the data points is shown in Figure 0.3.6. ◀

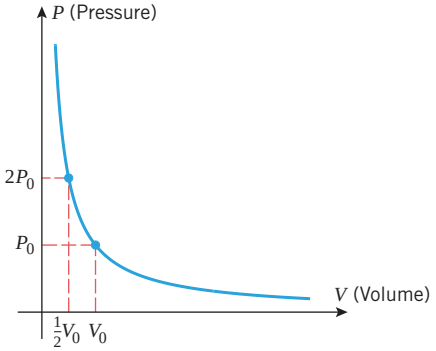
Inverse proportions arise in various laws of physics. For example, ***Boyle's law*** in physics states that *if a fixed amount of an ideal gas is held at a constant temperature, then the product of the pressure $P$ exerted by the gas and the volume $V$ that it occupies is constant*; that is,

$$PV = k$$

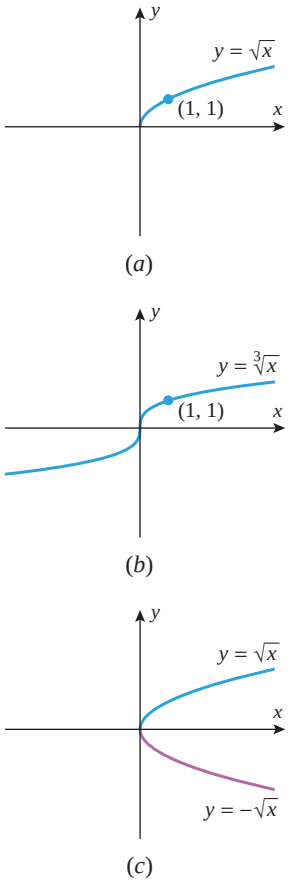
This implies that the variables $P$ and $V$ are inversely proportional to one another. Figure 0.3.7 shows a typical graph of volume versus pressure under the conditions of Boyle's law. Note how doubling the pressure corresponds to halving the volume, as expected.



▲ **Figure 0.3.6**



▲ **Figure 0.3.7** Doubling pressure corresponds to halving volume



▲ **Figure 0.3.8**

## POWER FUNCTIONS WITH NONINTEGER EXPONENTS

If $p = 1/n$, where $n$ is a positive integer, then the power functions $f(x) = x^p$ have the form

$$f(x) = x^{1/n} = \sqrt[n]{x}$$

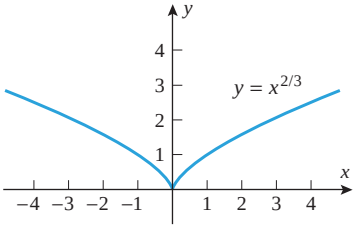
In particular, if $n = 2$, then $f(x) = \sqrt{x}$, and if $n = 3$, then $f(x) = \sqrt[3]{x}$. The graphs of these functions are shown in parts $(a)$ and $(b)$ of Figure 0.3.8.

Since every real number has a real cube root, the domain of the function $f(x) = \sqrt[3]{x}$ is $(-\infty, +\infty)$, and hence the graph of $y = \sqrt[3]{x}$ extends over the entire $x$-axis. In contrast, the graph of $y = \sqrt{x}$ extends only over the interval $[0, +\infty)$ because $\sqrt{x}$ is imaginary for negative $x$. As illustrated in Figure 0.3.8$c$, the graphs of $y = \sqrt{x}$ and $y = -\sqrt{x}$ form the upper and lower halves of the parabola $x = y^2$. In general, the graph of $y = \sqrt[n]{x}$ extends over the entire $x$-axis if $n$ is odd, but extends only over the interval $[0, +\infty)$ if $n$ is even.

Power functions can have other fractional exponents. Some examples are

$$f(x) = x^{2/3}, \quad f(x) = \sqrt[5]{x^3}, \quad f(x) = x^{-7/8} \tag{2}$$

The graph of $f(x) = x^{2/3}$ is shown in Figure 0.3.9. We will discuss expressions involving irrational exponents later.



▲ **Figure 0.3.9**

**TECHNOLOGY MASTERY**

Graphing utililties sometimes omit portions of the graph of a function involving fractional exponents (or radicals). If $f(x) = x^{p/q}$, where $p/q$ is a positive fraction in *lowest terms*, then you can circumvent this problem as follows:

- If $p$ is even and $q$ is odd, then graph $g(x) = |x|^{p/q}$ instead of $f(x)$.
- If $p$ is odd and $q$ is odd, then graph $g(x) = (|x|/x)|x|^{p/q}$ instead of $f(x)$.

Use a graphing utility to generate graphs of $f(x) = \sqrt[5]{x^3}$ and $f(x) = x^{-7/8}$ that show all of their significant features.

## POLYNOMIALS

A ***polynomial in x*** is a function that is expressible as a sum of finitely many terms of the form $cx^n$, where $c$ is a constant and $n$ is a nonnegative integer. Some examples of polynomials are

$$2x + 1, \quad 3x^2 + 5x - \sqrt{2}, \quad x^3, \quad 4\,(= 4x^0), \quad 5x^7 - x^4 + 3$$

The function $(x^2 - 4)^3$ is also a polynomial because it can be expanded by the binomial formula (see the inside front cover) and expressed as a sum of terms of the form $cx^n$:

$$(x^2 - 4)^3 = (x^2)^3 - 3(x^2)^2(4) + 3(x^2)(4^2) - (4^3) = x^6 - 12x^4 + 48x^2 - 64 \qquad (3)$$

A more detailed review of polynomials appears in Appendix C.

A general polynomial can be written in either of the following forms, depending on whether one wants the powers of $x$ in ascending or descending order:

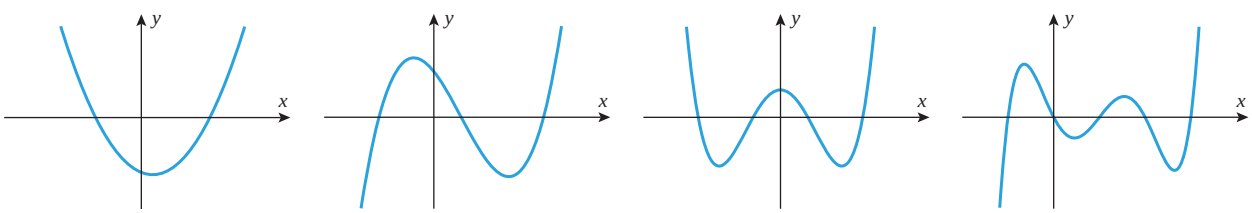
$$c_0 + c_1x + c_2x^2 + \cdots + c_nx^n$$
$$c_nx^n + c_{n-1}x^{n-1} + \cdots + c_1x + c_0$$

The constants $c_0, c_1, \ldots, c_n$ are called the ***coefficients*** of the polynomial. When a polynomial is expressed in one of these forms, the highest power of $x$ that occurs with a nonzero coefficient is called the ***degree*** of the polynomial. Nonzero constant polynomials are considered to have degree 0, since we can write $c = cx^0$. Polynomials of degree 1, 2, 3, 4, and 5 are described as ***linear***, ***quadratic***, ***cubic***, ***quartic***, and ***quintic***, respectively. For example,

The constant 0 is a polynomial called the *zero polynomial*. In this text we will take the degree of the zero polynomial to be undefined. Other texts may use different conventions for the degree of the zero polynomial.

| | | |
|---|---|---|
| $3 + 5x$ | $x^2 - 3x + 1$ | $2x^3 - 7$ |
| Has degree 1 (linear) | Has degree 2 (quadratic) | Has degree 3 (cubic) |
| $8x^4 - 9x^3 + 5x - 3$ | $\sqrt{3} + x^3 + x^5$ | $(x^2 - 4)^3$ |
| Has degree 4 (quartic) | Has degree 5 (quintic) | Has degree 6 [see (3)] |

The natural domain of a polynomial in $x$ is $(-\infty, +\infty)$, since the only operations involved are multiplication and addition; the range depends on the particular polynomial. We already know that the graphs of polynomials of degree 0 and 1 are lines and that the graphs of polynomials of degree 2 are parabolas. Figure 0.3.10 shows the graphs of some typical polynomials of higher degree. Later, we will discuss polynomial graphs in detail, but for now it suffices to observe that graphs of polynomials are very well behaved in the sense that they have no discontinuities or sharp corners. As illustrated in Figure 0.3.10, the graphs of polynomials wander up and down for awhile in a roller-coaster fashion, but eventually that behavior stops and the graphs steadily rise or fall indefinitely as one travels along the curve in either the positive or negative direction. We will see later that the number of peaks and valleys is less than the degree of the polynomial.



▲ **Figure 0.3.10**

## RATIONAL FUNCTIONS

A function that can be expressed as a ratio of two polynomials is called a ***rational function***. If $P(x)$ and $Q(x)$ are polynomials, then the domain of the rational function

$$f(x) = \frac{P(x)}{Q(x)}$$

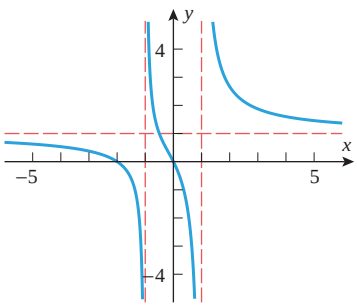
consists of all values of $x$ such that $Q(x) \neq 0$. For example, the domain of the rational function

$$f(x) = \frac{x^2 + 2x}{x^2 - 1}$$

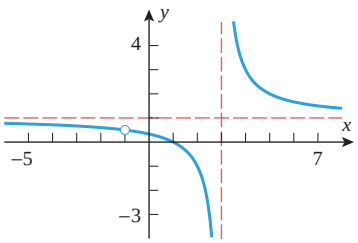
consists of all values of $x$, except $x = 1$ and $x = -1$. Its graph is shown in Figure 0.3.11 along with the graphs of two other typical rational functions.

The graphs of rational functions with nonconstant denominators differ from the graphs of polynomials in some essential ways:

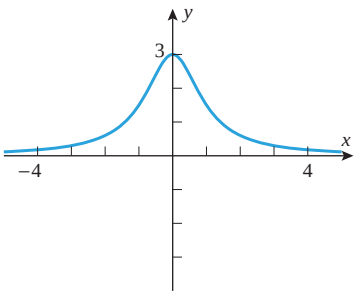
- Unlike polynomials whose graphs are continuous (unbroken) curves, the graphs of rational functions have discontinuities at the points where the denominator is zero.
- Unlike polynomials, rational functions may have numbers at which they are not defined. Near such points, many rational functions have graphs that closely approximate a vertical line, called a ***vertical asymptote***. These are represented by the dashed vertical lines in Figure 0.3.11.
- Unlike the graphs of nonconstant polynomials, which eventually rise or fall indefinitely, the graphs of many rational functions eventually get closer and closer to some horizontal line, called a ***horizontal asymptote***, as one traverses the curve in either the positive or negative direction. The horizontal asymptotes are represented by the dashed horizontal lines in the first two parts of Figure 0.3.11. In the third part of the figure the $x$-axis is a horizontal asymptote.



$$y = \frac{x^2 + 2x}{x^2 - 1}$$



$$y = \frac{x^2 - 1}{x^2 - 2x - 3}$$



$$y = \frac{3}{x^2 + 1}$$

▲ **Figure 0.3.11**

## ALGEBRAIC FUNCTIONS

Functions that can be constructed from polynomials by applying finitely many algebraic operations (addition, subtraction, multiplication, division, and root extraction) are called ***algebraic functions***. Some examples are

$$f(x) = \sqrt{x^2 - 4}, \quad f(x) = 3\sqrt[3]{x}(2 + x), \quad f(x) = x^{2/3}(x + 2)^2$$

As illustrated in Figure 0.3.12, the graphs of algebraic functions vary widely, so it is difficult to make general statements about them. Later in this text we will develop general calculus methods for analyzing such functions.

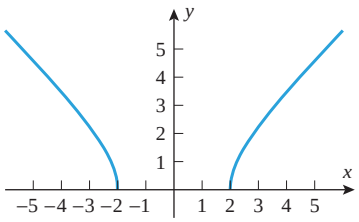
## THE FAMILIES $y = A \sin Bx$ AND $y = A \cos Bx$

In this text we will assume that the independent variable of a trigonometric function is in radians unless otherwise stated. A review of trigonometric functions can be found in Appendix B.

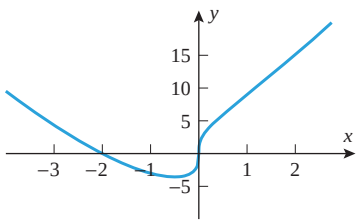
Many important applications lead to trigonometric functions of the form

$$f(x) = A\sin(Bx - C) \quad \text{and} \quad g(x) = A\cos(Bx - C) \tag{4}$$

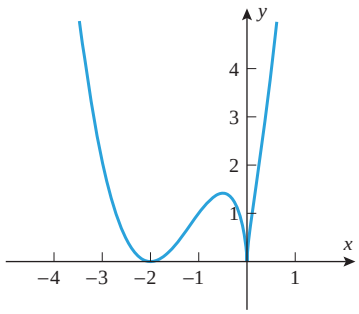
where $A$, $B$, and $C$ are nonzero constants. The graphs of such functions can be obtained by stretching, compressing, translating, and reflecting the graphs of $y = \sin x$ and $y = \cos x$



$y = \sqrt{x^2 - 4}$



$y = 3\sqrt[3]{x}\,(2 + x)$



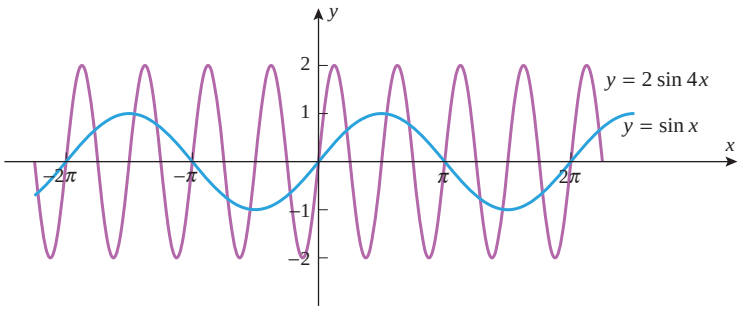
$y = x^{2/3}(x + 2)^2$

▲ **Figure 0.3.12**

appropriately. To see why this is so, let us start with the case where $C = 0$ and consider how the graphs of the equations

$$y = A \sin Bx \quad \text{and} \quad y = A \cos Bx$$

relate to the graphs of $y = \sin x$ and $y = \cos x$. If $A$ and $B$ are positive, then the effect of the constant $A$ is to stretch or compress the graphs of $y = \sin x$ and $y = \cos x$ vertically and the effect of the constant $B$ is to compress or stretch the graphs of $\sin x$ and $\cos x$ horizontally. For example, the graph of $y = 2 \sin 4x$ can be obtained by stretching the graph of $y = \sin x$ vertically by a factor of 2 and compressing it horizontally by a factor of 4. (Recall from Section 0.2 that the multiplier of $x$ *stretches* when it is less than 1 and *compresses* when it is greater than 1.) Thus, as shown in Figure 0.3.13, the graph of $y = 2 \sin 4x$ varies between $-2$ and 2, and repeats every $2\pi/4 = \pi/2$ units.



▶ **Figure 0.3.13**

In general, if $A$ and $B$ are positive numbers, then the graphs of

$$y = A \sin Bx \quad \text{and} \quad y = A \cos Bx$$

oscillate between $-A$ and $A$ and repeat every $2\pi/B$ units, so we say that these functions have ***amplitude*** $A$ and ***period*** $2\pi/B$. In addition, we define the ***frequency*** of these functions to be the reciprocal of the period, that is, the frequency is $B/2\pi$. If $A$ or $B$ is negative, then these constants cause reflections of the graphs about the axes as well as compressing or stretching them; and in this case the amplitude, period, and frequency are given by

$$\text{amplitude} = |A|, \quad \text{period} = \frac{2\pi}{|B|}, \quad \text{frequency} = \frac{|B|}{2\pi}$$

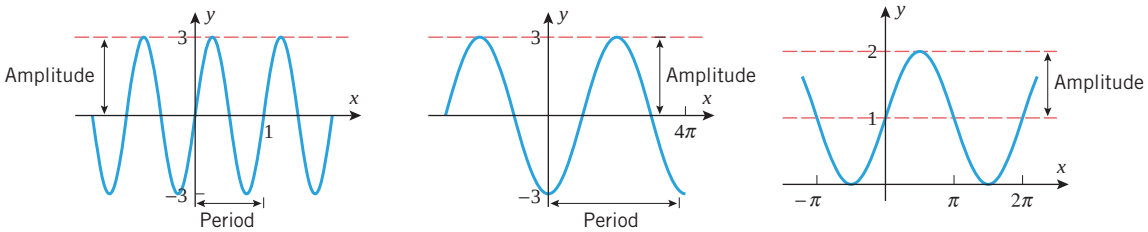
▶ **Example 2** Make sketches of the following graphs that show the period and amplitude.

(a) $y = 3 \sin 2\pi x$ (b) $y = -3 \cos 0.5x$ (c) $y = 1 + \sin x$

***Solution (a).*** The equation is of the form $y = A \sin Bx$ with $A = 3$ and $B = 2\pi$, so the graph has the shape of a sine function, but it has an amplitude of $A = 3$ and a period of $2\pi/B = 2\pi/2\pi = 1$ (Figure 0.3.14*a*).

***Solution (b).*** The equation is of the form $y = A \cos Bx$ with $A = -3$ and $B = 0.5$, so the graph has the shape of a cosine curve that has been reflected about the $x$-axis (because $A = -3$ is negative), but with amplitude $|A| = 3$ and period $2\pi/B = 2\pi/0.5 = 4\pi$ (Figure 0.3.14*b*).

***Solution (c).*** The graph has the shape of a sine curve that has been translated up 1 unit (Figure 0.3.14*c*). ◄



▲ **Figure 0.3.14**

## THE FAMILIES $y = A \sin(Bx - C)$ AND $y = A \cos(Bx - C)$

To investigate the graphs of the more general families

$$y = A \sin(Bx - C) \quad \text{and} \quad y = A \cos(Bx - C)$$

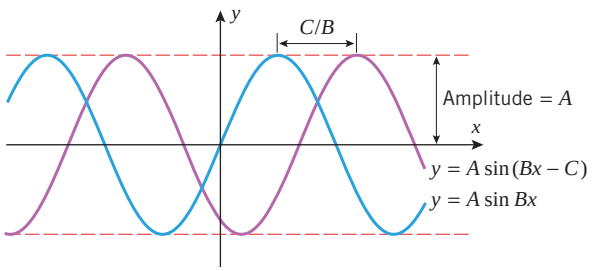
it will be helpful to rewrite these equations as

$$y = A \sin\left[B\left(x - \frac{C}{B}\right)\right] \quad \text{and} \quad y = A \cos\left[B\left(x - \frac{C}{B}\right)\right]$$

In this form we see that the graphs of these equations can be obtained by translating the graphs of $y = A \sin Bx$ and $y = A \cos Bx$ to the left or right, depending on the sign of $C/B$. For example, if $C/B > 0$, then the graph of

$$y = A \sin[B(x - C/B)] = A \sin(Bx - C)$$

can be obtained by translating the graph of $y = A \sin Bx$ to the right by $C/B$ units (Figure 0.3.15). If $C/B < 0$, the graph of $y = A \sin(Bx - C)$ is obtained by translating the graph of $y = A \sin Bx$ to the left by $|C/B|$ units.

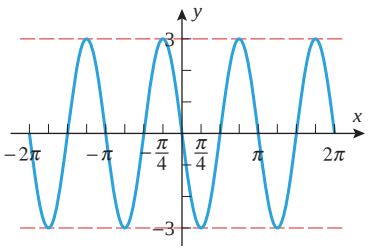


▶ **Figure 0.3.15**

▶ **Example 3** Find the amplitude and period of

$$y = 3 \cos\left(2x + \frac{\pi}{2}\right)$$

and determine how the graph of $y = 3\cos 2x$ should be translated to produce the graph of this equation. Confirm your results by graphing the equation on a calculator or computer.



▲ Figure 0.3.16

***Solution.*** The equation can be rewritten as

$$y = 3\cos\left[2x - \left(-\frac{\pi}{2}\right)\right] = 3\cos\left[2\left(x - \left(-\frac{\pi}{4}\right)\right)\right]$$

which is of the form

$$y = A\cos\left[B\left(x - \frac{C}{B}\right)\right]$$

with $A = 3$, $B = 2$, and $C/B = -\pi/4$. It follows that the amplitude is $A = 3$, the period is $2\pi/B = \pi$, and the graph is obtained by translating the graph of $y = 3\cos 2x$ left by $|C/B| = \pi/4$ units (Figure 0.3.16). ◀

## ✔ QUICK CHECK EXERCISES 0.3 (See page 38 for answers.)

1. Consider the family of functions $y = x^n$, where $n$ is an integer. The graphs of $y = x^n$ are symmetric with respect to the $y$-axis if $n$ is _____. These graphs are symmetric with respect to the origin if $n$ is _____. The $y$-axis is a vertical asymptote for these graphs if $n$ is _____.
2. What is the natural domain of a polynomial?
3. Consider the family of functions $y = x^{1/n}$, where $n$ is a nonzero integer. Find the natural domain of these functions if $n$ is
   (a) positive and even (b) positive and odd
   (c) negative and even (d) negative and odd.
4. Classify each equation as a polynomial, rational, algebraic, or not an algebraic function.
   (a) $y = \sqrt{x} + 2$ (b) $y = \sqrt{3}x^4 - x + 1$
   (c) $y = 5x^3 + \cos 4x$ (d) $y = \dfrac{x^2 + 5}{2x - 7}$
   (e) $y = 3x^2 + 4x^{-2}$
5. The graph of $y = A\sin Bx$ has amplitude _____ and is periodic with period _____.

## EXERCISE SET 0.3 Graphing Utility

1. (a) Find an equation for the family of lines whose members have slope $m = 3$.
   (b) Find an equation for the member of the family that passes through $(-1, 3)$.
   (c) Sketch some members of the family, and label them with their equations. Include the line in part (b).
2. Find an equation for the family of lines whose members are perpendicular to those in Exercise 1.
3. (a) Find an equation for the family of lines with $y$-intercept $b = 2$.
   (b) Find an equation for the member of the family whose angle of inclination is $135°$.
   (c) Sketch some members of the family, and label them with their equations. Include the line in part (b).
4. Find an equation for
   (a) the family of lines that pass through the origin
   (b) the family of lines with $x$-intercept $a = 1$
   (c) the family of lines that pass through the point $(1, -2)$
   (d) the family of lines parallel to $2x + 4y = 1$.
5. Find an equation for the family of lines tangent to the circle with center at the origin and radius 3.
6. Find an equation for the family of lines that pass through the intersection of $5x - 3y + 11 = 0$ and $2x - 9y + 7 = 0$.
7. The U.S. Internal Revenue Service uses a 10-year linear depreciation schedule to determine the value of various business items. This means that an item is assumed to have a value of zero at the end of the tenth year and that at intermediate times the value is a linear function of the elapsed time. Sketch some typical depreciation lines, and explain the practical significance of the $y$-intercepts.
8. Find all lines through $(6, -1)$ for which the product of the $x$- and $y$-intercepts is 3.

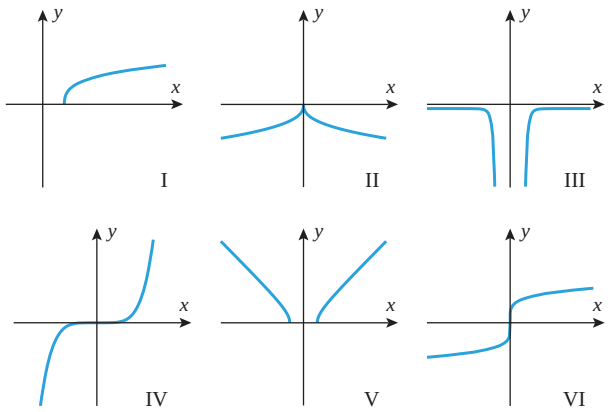
### FOCUS ON CONCEPTS

**9–10** State a geometric property common to all lines in the family, and sketch five of the lines. ■

9. (a) The family $y = -x + b$
   (b) The family $y = mx - 1$
   (c) The family $y = m(x + 4) + 2$
   (d) The family $x - ky = 1$

**10.** (a) The family $y = b$
(b) The family $Ax + 2y + 1 = 0$
(c) The family $2x + By + 1 = 0$
(d) The family $y - 1 = m(x + 1)$

**11.** In each part, match the equation with one of the accompanying graphs.
(a) $y = \sqrt[5]{x}$ (b) $y = 2x^5$
(c) $y = -1/x^8$ (d) $y = \sqrt{x^2 - 1}$
(e) $y = \sqrt[4]{x - 2}$ (f) $y = -\sqrt[5]{x^2}$



▲ **Figure Ex-11**

**12.** The accompanying table gives approximate values of three functions: one of the form $kx^2$, one of the form $kx^{-3}$, and one of the form $kx^{3/2}$. Identify which is which, and estimate $k$ in each case.

| $x$ | 0.25 | 0.37 | 2.1 | 4.0 | 5.8 | 6.2 | 7.9 | 9.3 |
|---|---|---|---|---|---|---|---|---|
| $f(x)$ | 640 | 197 | 1.08 | 0.156 | 0.0513 | 0.0420 | 0.0203 | 0.0124 |
| $g(x)$ | 0.0312 | 0.0684 | 2.20 | 8.00 | 16.8 | 19.2 | 31.2 | 43.2 |

**13–14** Sketch the graph of the equation for $n = 1$, 3, and 5 in one coordinate system and for $n = 2$, 4, and 6 in another coordinate system. If you have a graphing utility, use it to check your work. ■

**13.** (a) $y = -x^n$ (b) $y = 2x^{-n}$ (c) $y = (x - 1)^{1/n}$

**14.** (a) $y = 2x^n$ (b) $y = -x^{-n}$
(c) $y = -3(x + 2)^{1/n}$

**15.** (a) Sketch the graph of $y = ax^2$ for $a = \pm 1$, $\pm 2$, and $\pm 3$ in a single coordinate system.
(b) Sketch the graph of $y = x^2 + b$ for $b = \pm 1$, $\pm 2$, and $\pm 3$ in a single coordinate system.
(c) Sketch some typical members of the family of curves $y = ax^2 + b$.

**16.** (a) Sketch the graph of $y = a\sqrt{x}$ for $a = \pm 1$, $\pm 2$, and $\pm 3$ in a single coordinate system.
(b) Sketch the graph of $y = \sqrt{x} + b$ for $b = \pm 1$, $\pm 2$, and $\pm 3$ in a single coordinate system.
(c) Sketch some typical members of the family of curves $y = a\sqrt{x} + b$.

**17–18** Sketch the graph of the equation by making appropriate transformations to the graph of a basic power function. If you have a graphing utility, use it to check your work. ■

**17.** (a) $y = 2(x + 1)^2$ (b) $y = -3(x - 2)^3$
(c) $y = \dfrac{-3}{(x + 1)^2}$ (d) $y = \dfrac{1}{(x - 3)^5}$

**18.** (a) $y = 1 - \sqrt{x + 2}$ (b) $y = 1 - \sqrt[3]{x + 2}$
(c) $y = \dfrac{5}{(1 - x)^3}$ (d) $y = \dfrac{2}{(4 + x)^4}$

**19.** Sketch the graph of $y = x^2 + 2x$ by completing the square and making appropriate transformations to the graph of $y = x^2$.

**20.** (a) Use the graph of $y = \sqrt{x}$ to help sketch the graph of $y = \sqrt{|x|}$.
(b) Use the graph of $y = \sqrt[3]{x}$ to help sketch the graph of $y = \sqrt[3]{|x|}$.

**21.** As discussed in this section, Boyle's law states that at a constant temperature the pressure $P$ exerted by a gas is related to the volume $V$ by the equation $PV = k$.
(a) Find the appropriate units for the constant $k$ if pressure (which is force per unit area) is in newtons per square meter ($\text{N/m}^2$) and volume is in cubic meters ($\text{m}^3$).
(b) Find $k$ if the gas exerts a pressure of 20,000 $\text{N/m}^2$ when the volume is 1 liter (0.001 $\text{m}^3$).
(c) Make a table that shows the pressures for volumes of 0.25, 0.5, 1.0, 1.5, and 2.0 liters.
(d) Make a graph of $P$ versus $V$.

**22.** A manufacturer of cardboard drink containers wants to construct a closed rectangular container that has a square base and will hold $\frac{1}{10}$ liter (100 $\text{cm}^3$). Estimate the dimensions of the container that will require the least amount of material for its manufacture.

**23–24** A variable $y$ is said to be ***inversely proportional to the square of a variable*** $x$ if $y$ is related to $x$ by an equation of the form $y = k/x^2$, where $k$ is a nonzero constant, called the ***constant of proportionality***. This terminology is used in these exercises. ■

**23.** According to ***Coulomb's law***, the force $F$ of attraction between positive and negative point charges is inversely proportional to the square of the distance $x$ between them.
(a) Assuming that the force of attraction between two point charges is 0.0005 newton when the distance between them is 0.3 meter, find the constant of proportionality (with proper units).
(b) Find the force of attraction between the point charges when they are 3 meters apart.
(c) Make a graph of force versus distance for the two charges.

(cont.)

(d) What happens to the force as the particles get closer and closer together? What happens as they get farther and farther apart?

**24.** It follows from Newton's Law of Universal Gravitation that the weight $W$ of an object (relative to the Earth) is inversely proportional to the square of the distance $x$ between the object and the center of the Earth, that is, $W = C/x^2$.

(a) Assuming that a weather satellite weighs 2000 pounds on the surface of the Earth and that the Earth is a sphere of radius 4000 miles, find the constant $C$.

(b) Find the weight of the satellite when it is 1000 miles above the surface of the Earth.

(c) Make a graph of the satellite's weight versus its distance from the center of the Earth.

(d) Is there any distance from the center of the Earth at which the weight of the satellite is zero? Explain your reasoning.

**25–28 True–False** Determine whether the statement is true or false. Explain your answer. ■

**25.** Each curve in the family $y = 2x + b$ is parallel to the line $y = 2x$.

**26.** Each curve in the family $y = x^2 + bx + c$ is a translation of the graph of $y = x^2$.

**27.** If a curve passes through the point (2, 6) and $y$ is inversely proportional to $x$, then the constant of proportionality is 3.

**28.** Curves in the family $y = -5\sin(A\pi x)$ have amplitude 5 and period $2/|A|$.

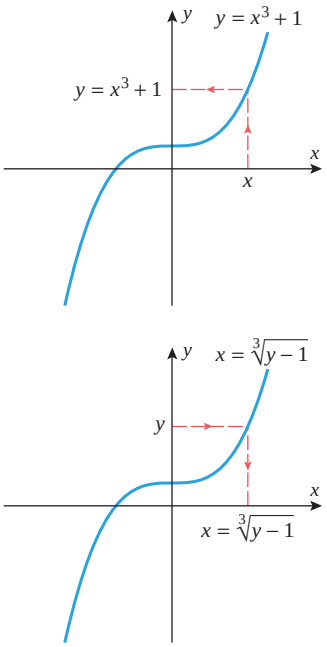
# 0.4 INVERSE FUNCTIONS; INVERSE TRIGONOMETRIC FUNCTIONS

*In everyday language the term "inversion" conveys the idea of a reversal. For example, in meteorology a temperature inversion is a reversal in the usual temperature properties of air layers, and in music a melodic inversion reverses an ascending interval to the corresponding descending interval. In mathematics the term* ***inverse*** *is used to describe functions that reverse one another in the sense that each undoes the effect of the other. In this section we discuss this fundamental mathematical idea. In particular, we introduce inverse trigonometric functions to address the problem of recovering an angle that could produce a given trigonometric function value.*



▲ Figure 0.4.1

## INVERSE FUNCTIONS

The idea of solving an equation $y = f(x)$ for $x$ as a function of $y$, say $x = g(y)$, is one of the most important ideas in mathematics. Sometimes, solving an equation is a simple process; for example, using basic algebra the equation

$$y = x^3 + 1 \qquad \boxed{y = f(x)}$$

can be solved for $x$ as a function of $y$:

$$x = \sqrt[3]{y - 1} \qquad \boxed{x = g(y)}$$

The first equation is better for computing $y$ if $x$ is known, and the second is better for computing $x$ if $y$ is known (Figure 0.4.1).

Our primary interest in this section is to identify relationships that may exist between the functions $f$ and $g$ when an equation $y = f(x)$ is expressed as $x = g(y)$, or conversely. For example, consider the functions $f(x) = x^3 + 1$ and $g(y) = \sqrt[3]{y - 1}$ discussed above. When these functions are composed in either order, they cancel out the effect of one another in the sense that

$$\begin{aligned} g(f(x)) &= \sqrt[3]{f(x) - 1} = \sqrt[3]{(x^3 + 1) - 1} = x \\ f(g(y)) &= [g(y)]^3 + 1 = (\sqrt[3]{y - 1})^3 + 1 = y \end{aligned} \tag{1}$$

Pairs of functions with these two properties are so important that there is special terminology for them.

**0.4.1 DEFINITION** If the functions $f$ and $g$ satisfy the two conditions

$$g(f(x)) = x \text{ for every } x \text{ in the domain of } f$$
$$f(g(y)) = y \text{ for every } y \text{ in the domain of } g$$

then we say that ***f is an inverse of g*** and ***g is an inverse of f*** or that ***f and g are inverse functions***.

**WARNING**

If $f$ is a function, then the $-1$ in the symbol $f^{-1}$ always denotes an inverse and *never* an exponent. That is,

$$f^{-1}(x) \quad \textit{never means} \quad \frac{1}{f(x)}$$

It can be shown (Exercise 62) that if a function $f$ has an inverse, then that inverse is unique. Thus, if a function $f$ has an inverse, then we are entitled to talk about "the" inverse of $f$, in which case we denote it by the symbol $f^{-1}$.

▶ **Example 1** The computations in (1) show that $g(y) = \sqrt[3]{y-1}$ is the inverse of $f(x) = x^3 + 1$. Thus, we can express $g$ in inverse notation as

$$f^{-1}(y) = \sqrt[3]{y-1}$$

and we can express the equations in Definition 0.4.1 as

$$\begin{aligned} f^{-1}(f(x)) &= x \quad \text{for every } x \text{ in the domain of } f \\ f(f^{-1}(y)) &= y \quad \text{for every } y \text{ in the domain of } f^{-1} \end{aligned} \tag{2}$$

We will call these the ***cancellation equations*** for $f$ and $f^{-1}$. ◀

## CHANGING THE INDEPENDENT VARIABLE

The formulas in (2) use $x$ as the independent variable for $f$ and $y$ as the independent variable for $f^{-1}$. Although it is often convenient to use different independent variables for $f$ and $f^{-1}$, there will be occasions on which it is desirable to use the same independent variable for both. For example, if we want to graph the functions $f$ and $f^{-1}$ together in the same $xy$-coordinate system, then we would want to use $x$ as the independent variable and $y$ as the dependent variable for both functions. Thus, to graph the functions $f(x) = x^3 + 1$ and $f^{-1}(y) = \sqrt[3]{y-1}$ of Example 1 in the same $xy$-coordinate system, we would change the independent variable $y$ to $x$, use $y$ as the dependent variable for both functions, and graph the equations

$$y = x^3 + 1 \quad \text{and} \quad y = \sqrt[3]{x-1}$$

We will talk more about graphs of inverse functions later in this section, but for reference we give the following reformulation of the cancellation equations in (2) using $x$ as the independent variable for both $f$ and $f^{-1}$:

$$\begin{aligned} f^{-1}(f(x)) &= x \quad \text{for every } x \text{ in the domain of } f \\ f(f^{-1}(x)) &= x \quad \text{for every } x \text{ in the domain of } f^{-1} \end{aligned} \tag{3}$$

▶ **Example 2** Confirm each of the following.

(a) The inverse of $f(x) = 2x$ is $f^{-1}(x) = \frac{1}{2}x$.

(b) The inverse of $f(x) = x^3$ is $f^{-1}(x) = x^{1/3}$.

The results in Example 2 should make sense to you intuitively, since the operations of multiplying by 2 and multiplying by $\frac{1}{2}$ in either order cancel the effect of one another, as do the operations of cubing and taking a cube root.

***Solution (a).***

$$f^{-1}(f(x)) = f^{-1}(2x) = \tfrac{1}{2}(2x) = x$$
$$f(f^{-1}(x)) = f\left(\tfrac{1}{2}x\right) = 2\left(\tfrac{1}{2}x\right) = x$$

***Solution (b).***

$$f^{-1}(f(x)) = f^{-1}(x^3) = (x^3)^{1/3} = x$$
$$f(f^{-1}(x)) = f(x^{1/3}) = (x^{1/3})^3 = x \quad \blacktriangleleft$$

**▶ Example 3** Given that the function $f$ has an inverse and that $f(3) = 5$, find $f^{-1}(5)$.

***Solution.*** Apply $f^{-1}$ to both sides of the equation $f(3) = 5$ to obtain

$$f^{-1}(f(3)) = f^{-1}(5)$$

and now apply the first equation in (3) to conclude that $f^{-1}(5) = 3$. ◀

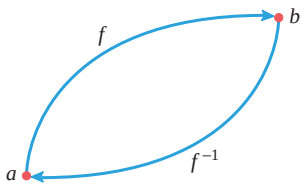
In general, if a function $f$ has an inverse and $f(a) = b$, then the procedure in Example 3 shows that $a = f^{-1}(b)$; that is, $f^{-1}$ maps each output of $f$ back into the corresponding input (Figure 0.4.2).

## DOMAIN AND RANGE OF INVERSE FUNCTIONS

The equations in (3) imply the following relationships between the domains and ranges of $f$ and $f^{-1}$:

$$\begin{aligned} &\text{domain of } f^{-1} = \text{range of } f \\ &\text{range of } f^{-1} = \text{domain of } f \end{aligned} \tag{4}$$

One way to show that two sets are the same is to show that each is a subset of the other. Thus we can establish the first equality in (4) by showing that the domain of $f^{-1}$ is a subset of the range of $f$ and that the range of $f$ is a subset of the domain of $f^{-1}$. We do this as follows: The first equation in (3) implies that $f^{-1}$ is defined at $f(x)$ for all values of $x$ in the domain of $f$, and this implies that the range of $f$ is a subset of the domain of $f^{-1}$. Conversely, if $x$ is in the domain of $f^{-1}$, then the second equation in (3) implies that $x$ is in the range of $f$ because it is the image of $f^{-1}(x)$. Thus, the domain of $f^{-1}$ is a subset of the range of $f$. We leave the proof of the second equation in (4) as an exercise.



▲ **Figure 0.4.2** If $f$ maps $a$ to $b$, then $f^{-1}$ maps $b$ back to $a$.

## A METHOD FOR FINDING INVERSE FUNCTIONS

At the beginning of this section we observed that solving $y = f(x) = x^3 + 1$ for $x$ as a function of $y$ produces $x = f^{-1}(y) = \sqrt[3]{y - 1}$. The following theorem shows that this is not accidental.

**0.4.2 THEOREM** *If an equation $y = f(x)$ can be solved for $x$ as a function of $y$, say $x = g(y)$, then $f$ has an inverse and that inverse is $g(y) = f^{-1}(y)$.*

**PROOF** Substituting $y = f(x)$ into $x = g(y)$ yields $x = g(f(x))$, which confirms the first equation in Definition 0.4.1, and substituting $x = g(y)$ into $y = f(x)$ yields $y = f(g(y))$, which confirms the second equation in Definition 0.4.1. ■

Theorem 0.4.2 provides us with the following procedure for finding the inverse of a function.

***A Procedure for Finding the Inverse of a Function f***

**Step 1.** Write down the equation $y = f(x)$.

**Step 2.** If possible, solve this equation for $x$ as a function of $y$.

**Step 3.** The resulting equation will be $x = f^{-1}(y)$, which provides a formula for $f^{-1}$ with $y$ as the independent variable.

**Step 4.** If $y$ is acceptable as the independent variable for the inverse function, then you are done, but if you want to have $x$ as the independent variable, then you need to interchange $x$ and $y$ in the equation $x = f^{-1}(y)$ to obtain $y = f^{-1}(x)$.

An alternative way to obtain a formula for $f^{-1}(x)$ with $x$ as the independent variable is to reverse the roles of $x$ and $y$ at the outset and solve the equation $x = f(y)$ for $y$ as a function of $x$.

▶ **Example 4** Find a formula for the inverse of $f(x) = \sqrt{3x - 2}$ with $x$ as the independent variable, and state the domain of $f^{-1}$.

***Solution.*** Following the procedure stated above, we first write

$$y = \sqrt{3x - 2}$$

Then we solve this equation for $x$ as a function of $y$:

$$y^2 = 3x - 2$$
$$x = \tfrac{1}{3}(y^2 + 2)$$

which tells us that

$$f^{-1}(y) = \tfrac{1}{3}(y^2 + 2) \tag{5}$$

Since we want $x$ to be the independent variable, we reverse $x$ and $y$ in (5) to produce the formula

$$f^{-1}(x) = \tfrac{1}{3}(x^2 + 2) \tag{6}$$

We know from (4) that the domain of $f^{-1}$ is the range of $f$. In general, this need not be the same as the natural domain of the fomula for $f^{-1}$. Indeed, in this example the natural domain of (6) is $(-\infty, +\infty)$, whereas the range of $f(x) = \sqrt{3x - 2}$ is $[0, +\infty)$. Thus, if we want to make the domain of $f^{-1}$ clear, we must express it explicitly by rewriting (6) as

$$f^{-1}(x) = \tfrac{1}{3}(x^2 + 2), \quad x \geq 0 \quad ◀$$

## EXISTENCE OF INVERSE FUNCTIONS

The procedure we gave above for finding the inverse of a function $f$ was based on solving the equation $y = f(x)$ for $x$ as a function of $y$. This procedure can fail for two reasons—the function $f$ may not have an inverse, or it may have an inverse but the equation $y = f(x)$ cannot be solved explicitly for $x$ as a function of $y$. Thus, it is important to establish conditions that ensure the existence of an inverse, even if it cannot be found explicitly.

If a function $f$ has an inverse, then it must assign distinct outputs to distinct inputs. For example, the function $f(x) = x^2$ cannot have an inverse because it assigns the same value to $x = 2$ and $x = -2$, namely,

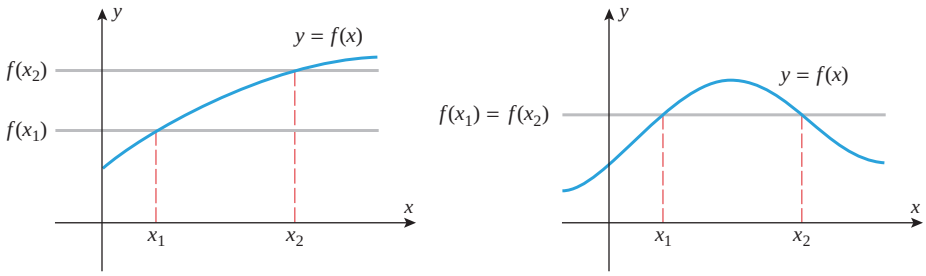
$$f(2) = f(-2) = 4$$

Thus, if $f(x) = x^2$ were to have an inverse, then the equation $f(2) = 4$ would imply that $f^{-1}(4) = 2$, and the equation $f(-2) = 4$ would imply that $f^{-1}(4) = -2$. But this is impossible because $f^{-1}(4)$ cannot have two different values. Another way to see that $f(x) = x^2$ has no inverse is to attempt to find the inverse by solving the equation $y = x^2$ for $x$ as a function of $y$. We run into trouble immediately because the resulting equation $x = \pm\sqrt{y}$ does not express $x$ as a *single* function of $y$.

A function that assigns distinct outputs to distinct inputs is said to be ***one-to-one*** or ***invertible***, so we know from the preceding discussion that if a function $f$ has an inverse, then it must be one-to-one. The converse is also true, thereby establishing the following theorem.

**0.4.3 THEOREM** *A function has an inverse if and only if it is one-to-one.*

Stated algebraically, a function $f$ is one-to-one if and only if $f(x_1) \neq f(x_2)$ whenever $x_1 \neq x_2$; stated geometrically, a function $f$ is one-to-one if and only if the graph of $y = f(x)$ is cut at most once by any horizontal line (Figure 0.4.3). The latter statement together with Theorem 0.4.3 provides the following geometric test for determining whether a function has an inverse.

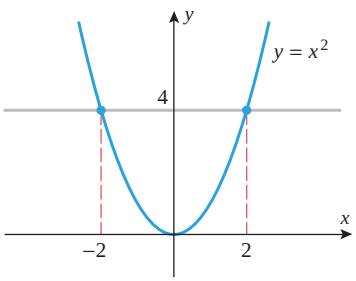


▶ Figure 0.4.3

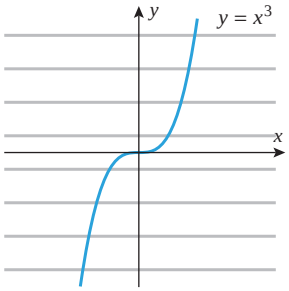
**0.4.4 THEOREM** (*The Horizontal Line Test*) *A function has an inverse function if and only if its graph is cut at most once by any horizontal line.*

▶ **Example 5** Use the horizontal line test to show that $f(x) = x^2$ has no inverse but that $f(x) = x^3$ does.

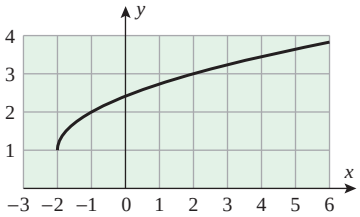
***Solution.*** Figure 0.4.4 shows a horizontal line that cuts the graph of $y = x^2$ more than once, so $f(x) = x^2$ is not invertible. Figure 0.4.5 shows that the graph of $y = x^3$ is cut at most once by any horizontal line, so $f(x) = x^3$ is invertible. [Recall from Example 2 that the inverse of $f(x) = x^3$ is $f^{-1}(x) = x^{1/3}$.] ◀



▲ Figure 0.4.4



▲ Figure 0.4.5



▲ Figure 0.4.6

▶ **Example 6** Explain why the function $f$ that is graphed in Figure 0.4.6 has an inverse, and find $f^{-1}(3)$.

***Solution.*** The function $f$ has an inverse since its graph passes the horizontal line test. To evaluate $f^{-1}(3)$, we view $f^{-1}(3)$ as that number $x$ for which $f(x) = 3$. From the graph we see that $f(2) = 3$, so $f^{-1}(3) = 2$. ◀

The function $f(x) = x^3$ in Figure 0.4.5 is an example of an increasing function. Give an example of a decreasing function and compute its inverse.

## INCREASING OR DECREASING FUNCTIONS ARE INVERTIBLE

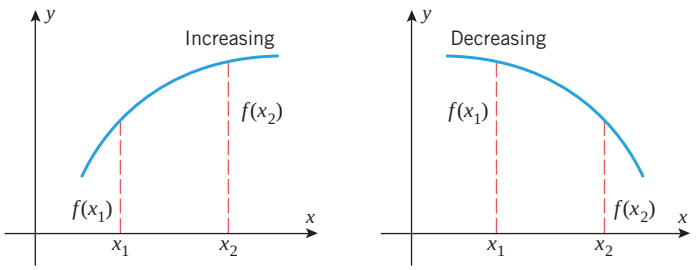
A function whose graph is always rising as it is traversed from left to right is said to be an ***increasing function***, and a function whose graph is always falling as it is traversed from left to right is said to be a ***decreasing function***. If $x_1$ and $x_2$ are points in the domain of a function $f$, then $f$ is increasing if

$$f(x_1) < f(x_2) \quad \text{whenever } x_1 < x_2$$

and $f$ is decreasing if

$$f(x_1) > f(x_2) \quad \text{whenever } x_1 < x_2$$

(Figure 0.4.7). It is evident geometrically that increasing and decreasing functions pass the horizontal line test and hence are invertible.

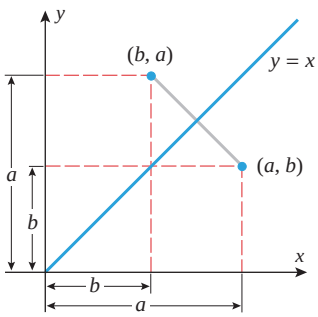


▶ **Figure 0.4.7**

## GRAPHS OF INVERSE FUNCTIONS

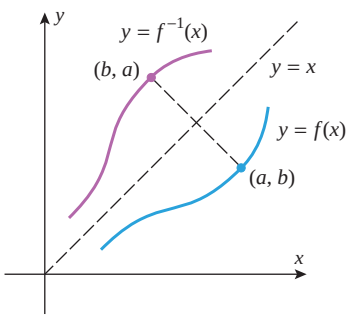
Our next objective is to explore the relationship between the graphs of $f$ and $f^{-1}$. For this purpose, it will be desirable to use $x$ as the independent variable for both functions so we can compare the graphs of $y = f(x)$ and $y = f^{-1}(x)$.

If $(a, b)$ is a point on the graph $y = f(x)$, then $b = f(a)$. This is equivalent to the statement that $a = f^{-1}(b)$, which means that $(b, a)$ is a point on the graph of $y = f^{-1}(x)$. In short, reversing the coordinates of a point on the graph of $f$ produces a point on the graph of $f^{-1}$. Similarly, reversing the coordinates of a point on the graph of $f^{-1}$ produces a point on the graph of $f$ (verify). However, the geometric effect of reversing the coordinates of a point is to reflect that point about the line $y = x$ (Figure 0.4.8), and hence the graphs of $y = f(x)$ and $y = f^{-1}(x)$ are reflections of one another about this line (Figure 0.4.9). In summary, we have the following result.



The points $(a, b)$ and $(b, a)$ are reflections about $y = x$.

▲ **Figure 0.4.8**

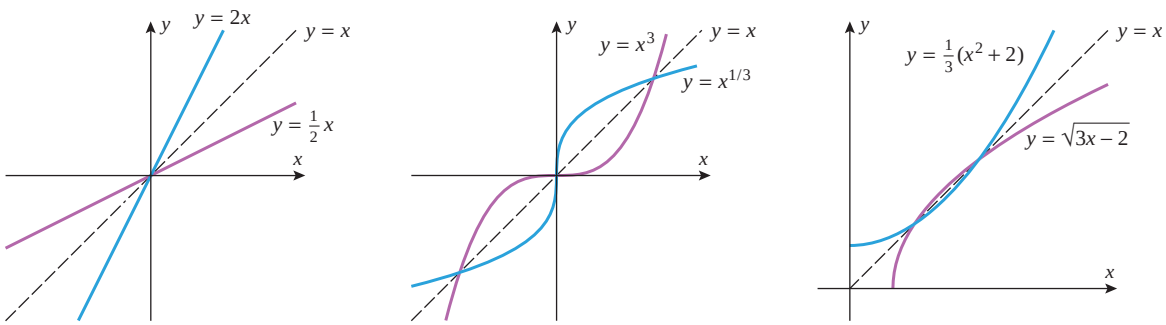


The graphs of $f$ and $f^{-1}$ are reflections about $y = x$.

▲ **Figure 0.4.9**

**0.4.5 THEOREM** *If $f$ has an inverse, then the graphs of $y = f(x)$ and $y = f^{-1}(x)$ are reflections of one another about the line $y = x$; that is, each graph is the mirror image of the other with respect to that line.*

▶ **Example 7** Figure 0.4.10 shows the graphs of the inverse functions discussed in Examples 2 and 4. ◀



▲ **Figure 0.4.10**

## RESTRICTING DOMAINS FOR INVERTIBILITY

If a function $g$ is obtained from a function $f$ by placing restrictions on the domain of $f$, then $g$ is called a ***restriction*** of $f$. Thus, for example, the function

$$g(x) = x^3, \quad x \geq 0$$

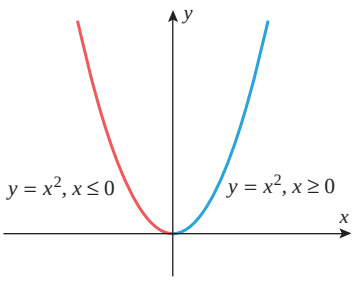
is a restriction of the function $f(x) = x^3$. More precisely, it is called the restriction of $x^3$ to the interval $[0, +\infty)$.

Sometimes it is possible to create an invertible function from a function that is not invertible by restricting the domain appropriately. For example, we showed earlier that $f(x) = x^2$ is not invertible. However, consider the restricted functions

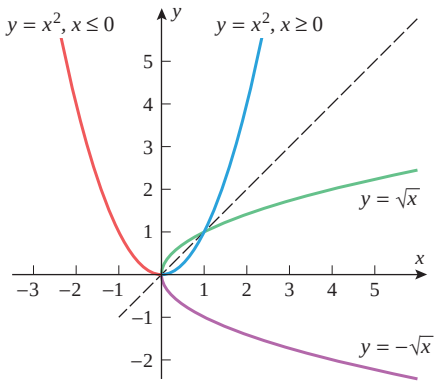
$$f_1(x) = x^2, \quad x \geq 0 \quad \text{and} \quad f_2(x) = x^2, \quad x \leq 0$$

the union of whose graphs is the complete graph of $f(x) = x^2$ (Figure 0.4.11). These restricted functions are each one-to-one (hence invertible), since their graphs pass the horizontal line test. As illustrated in Figure 0.4.12, their inverses are

$$f_1^{-1}(x) = \sqrt{x} \quad \text{and} \quad f_2^{-1}(x) = -\sqrt{x}$$



▲ Figure 0.4.11



▲ Figure 0.4.12

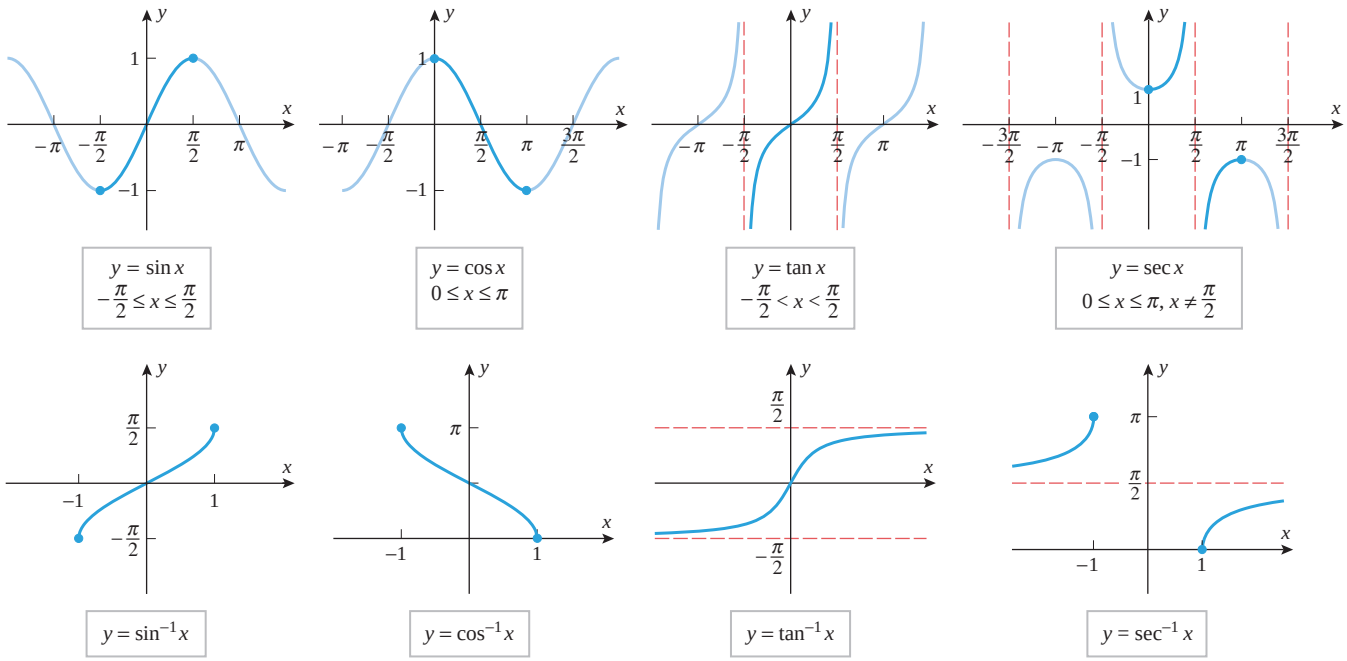
## INVERSE TRIGONOMETRIC FUNCTIONS

A common problem in trigonometry is to find an angle $x$ using a known value of $\sin x$, $\cos x$, or some other trigonometric function. Recall that problems of this type involve the computation of "arc functions" such as $\arcsin x$, $\arccos x$, and so forth. We will conclude this section by studying these arc functions from the viewpoint of general inverse functions.

The six basic trigonometric functions do not have inverses because their graphs repeat periodically and hence do not pass the horizontal line test. To circumvent this problem we will restrict the domains of the trigonometric functions to produce one-to-one functions and then define the "inverse trigonometric functions" to be the inverses of these restricted functions. The top part of Figure 0.4.13 shows geometrically how these restrictions are made for $\sin x$, $\cos x$, $\tan x$, and $\sec x$, and the bottom part of the figure shows the graphs of the corresponding inverse functions

$$\sin^{-1} x, \quad \cos^{-1} x, \quad \tan^{-1} x, \quad \sec^{-1} x$$

(also denoted by $\arcsin x$, $\arccos x$, $\arctan x$, and $\operatorname{arcsec} x$). Inverses of $\cot x$ and $\csc x$ are of lesser importance and will be considered in the exercises.



▲ **Figure 0.4.13**

If you have trouble visualizing the correspondence between the top and bottom parts of Figure 0.4.13, keep in mind that a reflection about $y = x$ converts vertical lines into horizontal lines, and vice versa; and it converts $x$-intercepts into $y$-intercepts, and vice versa.

The following formal definitions summarize the preceding discussion.

**0.4.6 DEFINITION** The *inverse sine function*, denoted by $\sin^{-1}$, is defined to be the inverse of the restricted sine function

$$\sin x, \quad -\pi/2 \le x \le \pi/2$$

**0.4.7 DEFINITION** The *inverse cosine function*, denoted by $\cos^{-1}$, is defined to be the inverse of the restricted cosine function

$$\cos x, \quad 0 \le x \le \pi$$

**0.4.8 DEFINITION** The *inverse tangent function*, denoted by $\tan^{-1}$, is defined to be the inverse of the restricted tangent function

$$\tan x, \quad -\pi/2 < x < \pi/2$$

**WARNING**

The notations $\sin^{-1} x, \cos^{-1} x, \ldots$ are reserved exclusively for the inverse trigonometric functions and are not used for reciprocals of the trigonometric functions. If we want to express the reciprocal $1/\sin x$ using an exponent, we would write $(\sin x)^{-1}$ and *never* $\sin^{-1} x$.

**0.4.9 DEFINITION*** The *inverse secant function*, denoted by $\sec^{-1}$, is defined to be the inverse of the restricted secant function

$$\sec x, \quad 0 \le x \le \pi \text{ with } x \ne \pi/2$$

*There is no universal agreement on the definition of $\sec^{-1} x$, and some mathematicians prefer to restrict the domain of $\sec x$ so that $0 \le x < \pi/2$ or $\pi \le x < 3\pi/2$, which was the definition used in some earlier editions of this text. Each definition has advantages and disadvantages, but we will use the current definition to conform with the conventions used by the CAS programs *Mathematica*, *Maple*, and *Sage*.

Table 0.4.1 summarizes the basic properties of the inverse trigonometric functions we have considered. You should confirm that the domains and ranges listed in this table are consistent with the graphs shown in Figure 0.4.13.

**Table 0.4.1**
PROPERTIES OF INVERSE TRIGONOMETRIC FUNCTIONS

| FUNCTION | DOMAIN | RANGE | BASIC RELATIONSHIPS |
|---|---|---|---|
| $\sin^{-1}$ | $[-1, 1]$ | $[-\pi/2, \pi/2]$ | $\sin^{-1}(\sin x) = x$ if $-\pi/2 \le x \le \pi/2$<br>$\sin(\sin^{-1} x) = x$ if $-1 \le x \le 1$ |
| $\cos^{-1}$ | $[-1, 1]$ | $[0, \pi]$ | $\cos^{-1}(\cos x) = x$ if $0 \le x \le \pi$<br>$\cos(\cos^{-1} x) = x$ if $-1 \le x \le 1$ |
| $\tan^{-1}$ | $(-\infty, +\infty)$ | $(-\pi/2, \pi/2)$ | $\tan^{-1}(\tan x) = x$ if $-\pi/2 < x < \pi/2$<br>$\tan(\tan^{-1} x) = x$ if $-\infty < x < +\infty$ |
| $\sec^{-1}$ | $(-\infty, -1] \cup [1, +\infty)$ | $[0, \pi/2) \cup (\pi/2, \pi]$ | $\sec^{-1}(\sec x) = x$ if $0 \le x \le \pi, x \ne \pi/2$<br>$\sec(\sec^{-1} x) = x$ if $\lvert x \rvert \ge 1$ |

## EVALUATING INVERSE TRIGONOMETRIC FUNCTIONS

A common problem in trigonometry is to find an angle whose sine is known. For example, you might want to find an angle $x$ in radian measure such that

$$\sin x = \tfrac{1}{2} \tag{7}$$

and, more generally, for a given value of $y$ in the interval $-1 \le y \le 1$ you might want to solve the equation

$$\sin x = y \tag{8}$$

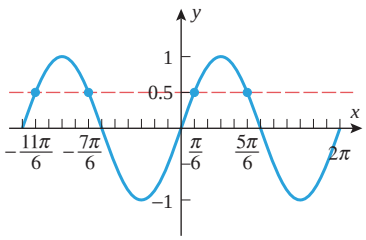
Because $\sin x$ repeats periodically, this equation has infinitely many solutions for $x$; however, if we solve this equation as

$$x = \sin^{-1} y$$

then we isolate the specific solution that lies in the interval $[-\pi/2, \pi/2]$, since this is the range of the inverse sine. For example, Figure 0.4.14 shows four solutions of Equation (7), namely, $-11\pi/6$, $-7\pi/6$, $\pi/6$, and $5\pi/6$. Of these, $\pi/6$ is the solution in the interval $[-\pi/2, \pi/2]$, so

$$\sin^{-1}\left(\tfrac{1}{2}\right) = \pi/6 \tag{9}$$

In general, if we view $x = \sin^{-1} y$ as an angle in radian measure whose sine is $y$, then the restriction $-\pi/2 \le x \le \pi/2$ imposes the geometric requirement that the angle $x$ in standard position terminate in either the first or fourth quadrant or on an axis adjacent to those quadrants.



▲ **Figure 0.4.14**

**TECHNOLOGY MASTERY**

Refer to the documentation for your calculating utility to determine how to calculate inverse sines, inverse cosines, and inverse tangents; and then confirm Equation (9) numerically by showing that

$$\sin^{-1}(0.5) \approx 0.523598775598\ldots \approx \pi/6$$

If $x = \cos^{-1} y$ is viewed as an angle in radian measure whose cosine is $y$, in what possible quadrants can $x$ lie? Answer the same question for

$$x = \tan^{-1} y \quad \text{and} \quad x = \sec^{-1} y$$

▶ **Example 8** Find exact values of

$$\text{(a) } \sin^{-1}(1/\sqrt{2}) \qquad \text{(b) } \sin^{-1}(-1)$$

by inspection, and confirm your results numerically using a calculating utility.

***Solution (a).*** Because $\sin^{-1}(1/\sqrt{2}) > 0$, we can view $x = \sin^{-1}(1/\sqrt{2})$ as that angle in the first quadrant such that $\sin\theta = 1/\sqrt{2}$. Thus, $\sin^{-1}(1/\sqrt{2}) = \pi/4$. You can confirm this with your calculating utility by showing that $\sin^{-1}(1/\sqrt{2}) \approx 0.785 \approx \pi/4$.

***Solution (b).*** Because $\sin^{-1}(-1) < 0$, we can view $x = \sin^{-1}(-1)$ as an angle in the fourth quadrant (or an adjacent axis) such that $\sin x = -1$. Thus, $\sin^{-1}(-1) = -\pi/2$. You can confirm this with your calculating utility by showing that $\sin^{-1}(-1) \approx -1.57 \approx -\pi/2$. ◀

**TECHNOLOGY MASTERY**

Most calculators do not provide a direct method for calculating inverse secants. In such situations the identity

$$\sec^{-1} x = \cos^{-1}(1/x) \tag{10}$$

is useful (Exercise 50). Use this formula to show that

$$\sec^{-1}(2.25) \approx 1.11 \quad \text{and} \quad \sec^{-1}(-2.25) \approx 2.03$$

If you have a calculating utility (such as a CAS) that can find $\sec^{-1} x$ directly, use it to check these values.

## IDENTITIES FOR INVERSE TRIGONOMETRIC FUNCTIONS

If we interpret $\sin^{-1} x$ as an angle in radian measure whose sine is $x$, and if that angle is *nonnegative*, then we can represent $\sin^{-1} x$ geometrically as an angle in a right triangle in which the hypotenuse has length 1 and the side opposite to the angle $\sin^{-1} x$ has length $x$ (Figure 0.4.15*a*). Moreover, the unlabeled acute angle in Figure 0.4.15*a* is $\cos^{-1} x$, since the cosine of that angle is $x$, and the unlabeled side in that figure has length $\sqrt{1-x^2}$ by the Theorem of Pythagoras (Figure 0.4.15*b*). This triangle motivates a number of useful identities involving inverse trigonometric functions that are valid for $-1 \le x \le 1$; for example,

$$\sin^{-1} x + \cos^{-1} x = \frac{\pi}{2} \tag{11}$$

$$\cos(\sin^{-1} x) = \sqrt{1-x^2} \tag{12}$$

$$\sin(\cos^{-1} x) = \sqrt{1-x^2} \tag{13}$$

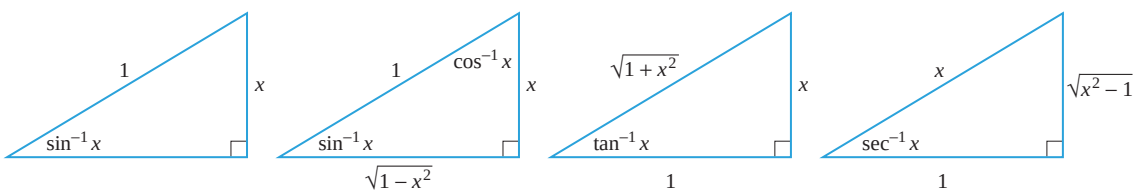
$$\tan(\sin^{-1} x) = \frac{x}{\sqrt{1-x^2}} \tag{14}$$

There is little to be gained by memorizing these identities. What is important is the mastery of the *method* used to obtain them.

In a similar manner, $\tan^{-1} x$ and $\sec^{-1} x$ can be represented as angles in the right triangles shown in Figures 0.4.15*c* and 0.4.15*d* (verify). Those triangles reveal additional useful identities; for example,

$$\sec(\tan^{-1} x) = \sqrt{1+x^2} \tag{15}$$

$$\sin(\sec^{-1} x) = \frac{\sqrt{x^2-1}}{x} \quad (x \ge 1) \tag{16}$$



▲ **Figure 0.4.15**

**REMARK**

The triangle technique does not always produce the most general form of an identity. For example, in Exercise 61 we will ask you to derive the following extension of Formula (16) that is valid for $x \le -1$ as well as $x \ge 1$:

$$\sin(\sec^{-1} x) = \frac{\sqrt{x^2-1}}{|x|} \quad (|x| \ge 1) \tag{17}$$

Referring to Figure 0.4.13, observe that the inverse sine and inverse tangent are odd functions; that is,

$$\sin^{-1}(-x) = -\sin^{-1}(x) \quad \text{and} \quad \tan^{-1}(-x) = -\tan^{-1}(x) \tag{18–19}$$

▶ **Example 9** Figure 0.4.16 shows a computer-generated graph of $y = \sin^{-1}(\sin x)$. One might think that this graph should be the line $y = x$, since $\sin^{-1}(\sin x) = x$. Why isn't it?

***Solution.*** The relationship $\sin^{-1}(\sin x) = x$ is valid on the interval $-\pi/2 \le x \le \pi/2$, so we can say with certainty that the graphs of $y = \sin^{-1}(\sin x)$ and $y = x$ coincide on this interval (which is confirmed by Figure 0.4.16). However, outside of this interval the relationship $\sin^{-1}(\sin x) = x$ does not hold. For example, if the quantity $x$ lies in the interval $\pi/2 \le x \le 3\pi/2$, then the quantity $x - \pi$ lies in the interval $-\pi/2 \le x \le \pi/2$, so

$$\sin^{-1}[\sin(x - \pi)] = x - \pi$$

Thus, by using the identity $\sin(x - \pi) = -\sin x$ and the fact that $\sin^{-1}$ is an odd function, we can express $\sin^{-1}(\sin x)$ as

$$\sin^{-1}(\sin x) = \sin^{-1}[-\sin(x - \pi)] = -\sin^{-1}[\sin(x - \pi)] = -(x - \pi)$$

This shows that on the interval $\pi/2 \le x \le 3\pi/2$ the graph of $y = \sin^{-1}(\sin x)$ coincides with the line $y = -(x - \pi)$, which has slope $-1$ and an $x$-intercept at $x = \pi$. This agrees with Figure 0.4.16. ◀

## ✔ QUICK CHECK EXERCISES 0.4 *(See page 52 for answers.)*

1. In each part, determine whether the function $f$ is one-to-one.
   (a) $f(t)$ is the number of people in line at a movie theater at time $t$.
   (b) $f(x)$ is the measured high temperature (rounded to the nearest °F) in a city on the $x$th day of the year.
   (c) $f(v)$ is the weight of $v$ cubic inches of lead.
2. A student enters a number on a calculator, doubles it, adds 8 to the result, divides the sum by 2, subtracts 3 from the quotient, and then cubes the difference. If the resulting number is $x$, then _____ was the student's original number.
3. If $(3, -2)$ is a point on the graph of an odd invertible function $f$, then _____ and _____ are points on the graph of $f^{-1}$.
4. In each part, determine the exact value without using a calculating utility.
   (a) $\sin^{-1}(-1) =$ _____
   (b) $\tan^{-1}(1) =$ _____
   (c) $\sin^{-1}\left(\frac{1}{2}\sqrt{3}\right) =$ _____
   (d) $\cos^{-1}\left(\frac{1}{2}\right) =$ _____
   (e) $\sec^{-1}(-2) =$ _____
5. In each part, determine the exact value without using a calculating utility.
   (a) $\sin^{-1}(\sin \pi/7) =$ _____
   (b) $\sin^{-1}(\sin 5\pi/7) =$ _____
   (c) $\tan^{-1}(\tan 13\pi/6) =$ _____
   (d) $\cos^{-1}(\cos 12\pi/7) =$ _____

## EXERCISE SET 0.4 Graphing Utility

1. In (a)–(d), determine whether $f$ and $g$ are inverse functions.
   (a) $f(x) = 4x,\ g(x) = \frac{1}{4}x$
   (b) $f(x) = 3x + 1,\ g(x) = 3x - 1$
   (c) $f(x) = \sqrt[3]{x - 2},\ g(x) = x^3 + 2$
   (d) $f(x) = x^4,\ g(x) = \sqrt[4]{x}$

2. Check your answers to Exercise 1 with a graphing utility by determining whether the graphs of $f$ and $g$ are reflections of one another about the line $y = x$.

3. In each part, use the horizontal line test to determine whether the function $f$ is one-to-one.
   (a) $f(x) = 3x + 2$
   (b) $f(x) = \sqrt{x - 1}$
   (c) $f(x) = |x|$
   (d) $f(x) = x^3$
   (e) $f(x) = x^2 - 2x + 2$
   (f) $f(x) = \sin x$

4. In each part, generate the graph of the function $f$ with a graphing utility, and determine whether $f$ is one-to-one.
   (a) $f(x) = x^3 - 3x + 2$
   (b) $f(x) = x^3 - 3x^2 + 3x - 1$

**FOCUS ON CONCEPTS**

**5.** In each part, determine whether the function $f$ defined by the table is one-to-one.

(a)

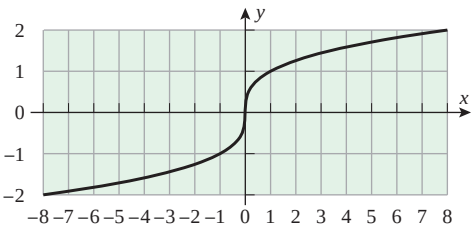
| $x$ | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| $f(x)$ | −2 | −1 | 0 | 1 | 2 | 3 |

(b)

| $x$ | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|
| $f(x)$ | 4 | −7 | 6 | −3 | 1 | 4 |

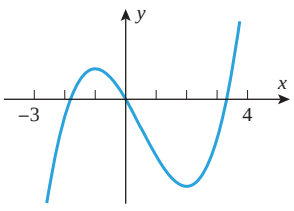
**6.** A face of a broken clock lies in the $xy$-plane with the center of the clock at the origin and 3:00 in the direction of the positive $x$-axis. When the clock broke, the tip of the hour hand stopped on the graph of $y = f(x)$, where $f$ is a function that satisfies $f(0) = 0$.
(a) Are there any times of the day that cannot appear in such a configuration? Explain.
(b) How does your answer to part (a) change if $f$ must be an invertible function?
(c) How do your answers to parts (a) and (b) change if it was the tip of the minute hand that stopped on the graph of $f$?

**7.** (a) The accompanying figure shows the graph of a function $f$ over its domain $-8 \le x \le 8$. Explain why $f$ has an inverse, and use the graph to find $f^{-1}(2)$, $f^{-1}(-1)$, and $f^{-1}(0)$.
(b) Find the domain and range of $f^{-1}$.
(c) Sketch the graph of $f^{-1}$.



▲ **Figure Ex-7**

**8.** (a) Explain why the function $f$ graphed in the accompanying figure has no inverse function on its domain $-3 \le x \le 4$.
(b) Subdivide the domain into three adjacent intervals on each of which the function $f$ has an inverse.



◀ **Figure Ex-8**

**9–16** Find a formula for $f^{-1}(x)$. ■

**9.** $f(x) = 7x - 6$

**10.** $f(x) = \dfrac{x+1}{x-1}$

**11.** $f(x) = 3x^3 - 5$

**12.** $f(x) = \sqrt[5]{4x+2}$

**13.** $f(x) = 3/x^2, \quad x < 0$

**14.** $f(x) = 5/(x^2+1), \quad x \ge 0$

**15.** $f(x) = \begin{cases} 5/2 - x, & x < 2 \\ 1/x, & x \ge 2 \end{cases}$

**16.** $f(x) = \begin{cases} 2x, & x \le 0 \\ x^2, & x > 0 \end{cases}$

**17–20** Find a formula for $f^{-1}(x)$, and state the domain of the function $f^{-1}$. ■

**17.** $f(x) = (x+2)^4, \quad x \ge 0$

**18.** $f(x) = \sqrt{x+3}$

**19.** $f(x) = -\sqrt{3-2x}$

**20.** $f(x) = x - 5x^2, \quad x \ge 1$

**21.** Let $f(x) = ax^2 + bx + c$, $a > 0$. Find $f^{-1}$ if the domain of $f$ is restricted to
(a) $x \ge -b/(2a)$ (b) $x \le -b/(2a)$.

**FOCUS ON CONCEPTS**

**22.** The formula $F = \frac{9}{5}C + 32$, where $C \ge -273.15$ expresses the Fahrenheit temperature $F$ as a function of the Celsius temperature $C$.
(a) Find a formula for the inverse function.
(b) In words, what does the inverse function tell you?
(c) Find the domain and range of the inverse function.

**23.** (a) One meter is about $6.214 \times 10^{-4}$ miles. Find a formula $y = f(x)$ that expresses a length $y$ in meters as a function of the same length $x$ in miles.
(b) Find a formula for the inverse of $f$.
(c) Describe what the formula $x = f^{-1}(y)$ tells you in practical terms.

**24.** Let $f(x) = x^2$, $x > 1$, and $g(x) = \sqrt{x}$.
(a) Show that $f(g(x)) = x$, $x > 1$, and $g(f(x)) = x$, $x > 1$.
(b) Show that $f$ and $g$ are *not* inverses by showing that the graphs of $y = f(x)$ and $y = g(x)$ are not reflections of one another about $y = x$.
(c) Do parts (a) and (b) contradict one another? Explain.

**25.** (a) Show that $f(x) = (3-x)/(1-x)$ is its own inverse.
(b) What does the result in part (a) tell you about the graph of $f$?

**26.** Sketch the graph of a function that is one-to-one on $(-\infty, +\infty)$, yet not increasing on $(-\infty, +\infty)$ and not decreasing on $(-\infty, +\infty)$.

**27.** Let $f(x) = 2x^3 + 5x + 3$. Find $x$ if $f^{-1}(x) = 1$.

**28.** Let $f(x) = \dfrac{x^3}{x^2+1}$. Find $x$ if $f^{-1}(x) = 2$.

**29.** Prove that if $a^2 + bc \neq 0$, then the graph of

$$f(x) = \frac{ax + b}{cx - a}$$

is symmetric about the line $y = x$.

**30.** (a) Prove: If $f$ and $g$ are one-to-one, then so is the composition $f \circ g$.

(b) Prove: If $f$ and $g$ are one-to-one, then

$$(f \circ g)^{-1} = g^{-1} \circ f^{-1}$$

**31–34 True–False** Determine whether the statement is true or false. Explain your answer. ■

**31.** If $f$ is an invertible function such that $f(2) = 2$, then $f^{-1}(2) = \frac{1}{2}$.

**32.** If $f$ and $g$ are inverse functions, then $f$ and $g$ have the same domain.

**33.** A one-to-one function is invertible.

**34.** The range of the inverse tangent function is the interval $-\pi/2 \leq y \leq \pi/2$.

**35.** Given that $\theta = \tan^{-1}\left(\frac{4}{3}\right)$, find the exact values of $\sin\theta$, $\cos\theta$, $\cot\theta$, $\sec\theta$, and $\csc\theta$.

**36.** Given that $\theta = \sec^{-1} 2.6$, find the exact values of $\sin\theta$, $\cos\theta$, $\tan\theta$, $\cot\theta$, and $\csc\theta$.

**37.** For which values of $x$ is it true that

(a) $\cos^{-1}(\cos x) = x$ (b) $\cos(\cos^{-1} x) = x$

(c) $\tan^{-1}(\tan x) = x$ (d) $\tan(\tan^{-1} x) = x$?

**38–39** Find the exact value of the given quantity. ■

**38.** $\sec\left[\sin^{-1}\left(-\frac{3}{4}\right)\right]$ **39.** $\sin\left[2\cos^{-1}\left(\frac{3}{5}\right)\right]$

**40–41** Complete the identities using the triangle method (Figure 0.4.15). ■

**40.** (a) $\sin(\cos^{-1} x) = ?$ (b) $\tan(\cos^{-1} x) = ?$

(c) $\csc(\tan^{-1} x) = ?$ (d) $\sin(\tan^{-1} x) = ?$

**41.** (a) $\cos(\tan^{-1} x) = ?$ (b) $\tan(\cos^{-1} x) = ?$

(c) $\sin(\sec^{-1} x) = ?$ (d) $\cot(\sec^{-1} x) = ?$

**42.** (a) Use a calculating utility set to radian measure to make tables of values of $y = \sin^{-1} x$ and $y = \cos^{-1} x$ for $x = -1, -0.8, -0.6, \ldots, 0, 0.2, \ldots, 1$. Round your answers to two decimal places.

(b) Plot the points obtained in part (a), and use the points to sketch the graphs of $y = \sin^{-1} x$ and $y = \cos^{-1} x$. Confirm that your sketches agree with those in Figure 0.4.13.

(c) Use your graphing utility to graph $y = \sin^{-1} x$ and $y = \cos^{-1} x$; confirm that the graphs agree with those in Figure 0.4.13.

**43.** In each part, sketch the graph and check your work with a graphing utility.

(a) $y = \sin^{-1} 2x$ (b) $y = \tan^{-1} \frac{1}{2}x$

**44.** The ***law of cosines*** states that

$$c^2 = a^2 + b^2 - 2ab\cos\theta$$

where $a$, $b$, and $c$ are the lengths of the sides of a triangle and $\theta$ is the angle formed by sides $a$ and $b$. Find $\theta$, to the nearest degree, for the triangle with $a = 2$, $b = 3$, and $c = 4$.

**45–46** Use a calculating utility to approximate the solution of each equation. Where radians are used, express your answer to four decimal places, and where degrees are used, express it to the nearest tenth of a degree. [*Note:* In each part, the solution is not in the range of the relevant inverse trigonometric function.] ■

**45.** (a) $\sin x = 0.37,\ \pi/2 < x < \pi$

(b) $\sin\theta = -0.61,\ 180° < \theta < 270°$

**46.** (a) $\cos x = -0.85,\ \pi < x < 3\pi/2$

(b) $\cos\theta = 0.23,\ -90° < \theta < 0°$

**FOCUS ON CONCEPTS**

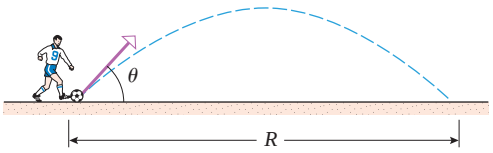
**47.** (a) Use a calculating utility to evaluate the expressions $\sin^{-1}(\sin^{-1} 0.25)$ and $\sin^{-1}(\sin^{-1} 0.9)$, and explain what you think is happening in the second calculation.

(b) For what values of $x$ in the interval $-1 \leq x \leq 1$ will your calculating utility produce a real value for the function $\sin^{-1}(\sin^{-1} x)$?

**48.** A soccer player kicks a ball with an initial speed of 14 m/s at an angle $\theta$ with the horizontal (see the accompanying figure). The ball lands 18 m down the field. If air resistance is neglected, then the ball will have a parabolic trajectory and the horizontal range $R$ will be given by

$$R = \frac{v^2}{g}\sin 2\theta$$

where $v$ is the initial speed of the ball and $g$ is the acceleration due to gravity. Using $g = 9.8\ \text{m/s}^2$, approximate two values of $\theta$, to the nearest degree, at which the ball could have been kicked. Which angle results in the shorter time of flight? Why?



▲ **Figure Ex-48**

**49–50** The function $\cot^{-1} x$ is defined to be the inverse of the restricted cotangent function

$$\cot x, \quad 0 < x < \pi$$

and the function $\csc^{-1} x$ is defined to be the inverse of the restricted cosecant function

$$\csc x, \quad -\pi/2 < x < \pi/2, \quad x \neq 0$$

Use these definitions in these and in all subsequent exercises that involve these functions. ■

**49.** (a) Sketch the graphs of $\cot^{-1} x$ and $\csc^{-1} x$.
(b) Find the domain and range of $\cot^{-1} x$ and $\csc^{-1} x$.

**50.** Show that

(a) $\cot^{-1} x = \begin{cases} \tan^{-1}(1/x), & \text{if } x > 0 \\ \pi + \tan^{-1}(1/x), & \text{if } x < 0 \end{cases}$

(b) $\sec^{-1} x = \cos^{-1} \dfrac{1}{x}, \quad \text{if } |x| \geq 1$

(c) $\csc^{-1} x = \sin^{-1} \dfrac{1}{x}, \quad \text{if } |x| \geq 1.$

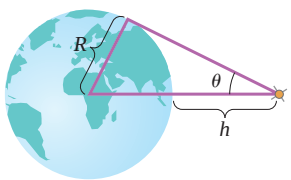
**51.** Most scientific calculators have keys for the values of only $\sin^{-1} x$, $\cos^{-1} x$, and $\tan^{-1} x$. The formulas in Exercise 50 show how a calculator can be used to obtain values of $\cot^{-1} x$, $\sec^{-1} x$, and $\csc^{-1} x$ for positive values of $x$. Use these formulas and a calculator to find numerical values for each of the following inverse trigonometric functions. Express your answers in degrees, rounded to the nearest tenth of a degree.

(a) $\cot^{-1} 0.7$ (b) $\sec^{-1} 1.2$ (c) $\csc^{-1} 2.3$

**52.** An Earth-observing satellite has horizon sensors that can measure the angle $\theta$ shown in the accompanying figure. Let $R$ be the radius of the Earth (assumed spherical) and $h$ the distance between the satellite and the Earth's surface.

(a) Show that $\sin\theta = \dfrac{R}{R+h}$.

(b) Find $\theta$, to the nearest degree, for a satellite that is 10,000 km from the Earth's surface (use $R = 6378$ km).



◀ **Figure Ex-52**

**53.** The number of hours of daylight on a given day at a given point on the Earth's surface depends on the latitude $\lambda$ of the point, the angle $\gamma$ through which the Earth has moved in its orbital plane during the time period from the vernal equinox (March 21), and the angle of inclination $\phi$ of the Earth's axis of rotation measured from ecliptic north ($\phi \approx 23.45°$). The number of hours of daylight $h$ can be approximated by the formula

$$h = \begin{cases} 24, & D \geq 1 \\ 12 + \frac{2}{15}\sin^{-1} D, & |D| < 1 \\ 0, & D \leq -1 \end{cases}$$

where

$$D = \frac{\sin\phi \sin\gamma \tan\lambda}{\sqrt{1 - \sin^2\phi \sin^2\gamma}}$$

and $\sin^{-1} D$ is in degree measure. Given that Fairbanks, Alaska, is located at a latitude of $\lambda = 65°$ N and also that $\gamma = 90°$ on June 20 and $\gamma = 270°$ on December 20, approximate

(a) the maximum number of daylight hours at Fairbanks to one decimal place

(b) the minimum number of daylight hours at Fairbanks to one decimal place.

## 0.5 EXPONENTIAL AND LOGARITHMIC FUNCTIONS

*When logarithms were introduced in the seventeenth century as a computational tool, they provided scientists of that period computing power that was previously unimaginable. Although computers and calculators have replaced logarithm tables for numerical calculations, the logarithmic functions have wide-ranging applications in mathematics and science. In this section we will review some properties of exponents and logarithms and then use our work on inverse functions to develop results about exponential and logarithmic functions.*

### IRRATIONAL EXPONENTS

Recall from algebra that if $b$ is a nonzero real number, then nonzero *integer* powers of $b$ are defined by

$$b^n = \underbrace{b \times b \times \cdots \times b}_{n \text{ factors}} \quad \text{and} \quad b^{-n} = \frac{1}{b^n}$$

and if $n = 0$, then $b^0 = 1$. Also, if $p/q$ is a positive *rational* number expressed in lowest terms, then

$$b^{p/q} = \sqrt[q]{b^p} = (\sqrt[q]{b})^p \quad \text{and} \quad b^{-p/q} = \frac{1}{b^{p/q}}$$

If $b$ is negative, then some fractional powers of $b$ will have imaginary values—the quantity $(-2)^{1/2} = \sqrt{-2}$, for example. To avoid this complication, we will assume throughout this section that $b > 0$, even if it is not stated explicitly.

There are various methods for defining *irrational* powers such as

$$2^{\pi}, \quad 3^{\sqrt{2}}, \quad \pi^{-\sqrt{7}}$$

One approach is to define irrational powers of $b$ via successive approximations using rational powers of $b$. For example, to define $2^{\pi}$ consider the decimal representation of $\pi$:

$$3.1415926\ldots$$

From this decimal we can form a sequence of rational numbers that gets closer and closer to $\pi$, namely,

$$3.1, \quad 3.14, \quad 3.141, \quad 3.1415, \quad 3.14159$$

and from these we can form a sequence of *rational* powers of 2:

$$2^{3.1}, \quad 2^{3.14}, \quad 2^{3.141}, \quad 2^{3.1415}, \quad 2^{3.14159}$$

Since the exponents of the terms in this sequence get successively closer to $\pi$, it seems plausible that the terms themselves will get successively closer to some number. It is that number that we *define* to be $2^{\pi}$. This is illustrated in Table 0.5.1, which we generated using

**Table 0.5.1**

| $x$ | $2^x$ |
|---|---|
| 3 | 8.000000 |
| 3.1 | 8.574188 |
| 3.14 | 8.815241 |
| 3.141 | 8.821353 |
| 3.1415 | 8.824411 |
| 3.14159 | 8.824962 |
| 3.141592 | 8.824974 |
| 3.1415926 | 8.824977 |

a calculator. The table suggests that to four decimal places the value of $2^{\pi}$ is

$$2^{\pi} \approx 8.8250 \tag{1}$$

**TECHNOLOGY MASTERY**

Use a calculating utility to verify the results in Table 0.5.1, and then verify (1) by using the utility to compute $2^{\pi}$ directly.

With this notion for irrational powers, we remark without proof that the following familiar laws of exponents hold for all real values of $p$ and $q$:

$$b^p b^q = b^{p+q}, \quad \frac{b^p}{b^q} = b^{p-q}, \quad (b^p)^q = b^{pq}$$

## THE FAMILY OF EXPONENTIAL FUNCTIONS

A function of the form $f(x) = b^x$, where $b > 0$, is called an ***exponential function with base b***. Some examples are

$$f(x) = 2^x, \quad f(x) = \left(\tfrac{1}{2}\right)^x, \quad f(x) = \pi^x$$

Note that an exponential function has a constant base and variable exponent. Thus, functions such as $f(x) = x^2$ and $f(x) = x^{\pi}$ would *not* be classified as exponential functions, since they have a variable base and a constant exponent.

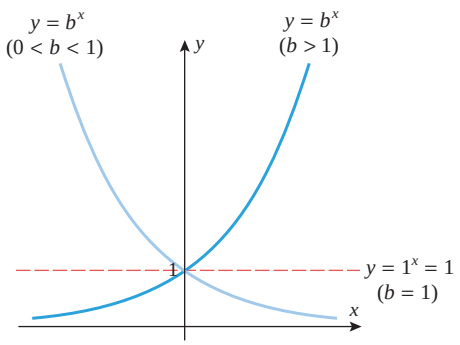
Figure 0.5.1 illustrates that the graph of $y = b^x$ has one of three general forms, depending on the value of $b$. The graph of $y = b^x$ has the following properties:

- The graph passes through $(0, 1)$ because $b^0 = 1$.
- If $b > 1$, the value of $b^x$ increases as $x$ increases. As you traverse the graph of $y = b^x$ from left to right, the values of $b^x$ increase indefinitely. If you traverse the graph from right to left, the values of $b^x$ decrease toward zero but never reach zero. Thus, the $x$-axis is a horizontal asymptote of the graph of $b^x$.
- If $0 < b < 1$, the value of $b^x$ decreases as $x$ increases. As you traverse the graph of $y = b^x$ from left to right, the values of $b^x$ decrease toward zero but never reach zero. Thus, the $x$-axis is a horizontal asymptote of the graph of $b^x$. If you traverse the graph from right to left, the values of $b^x$ increase indefinitely.
- If $b = 1$, then the value of $b^x$ is constant.

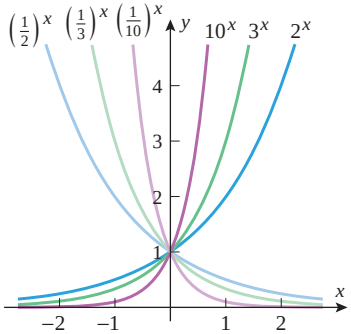
Some typical members of the family of exponential functions are graphed in Figure 0.5.2. This figure illustrates that the graph of $y = (1/b)^x$ is the reflection of the graph of $y = b^x$ about the $y$-axis. This is because replacing $x$ by $-x$ in the equation $y = b^x$ yields

$$y = b^{-x} = (1/b)^x$$

The figure also conveys that for $b > 1$, the larger the base $b$, the more rapidly the function $f(x) = b^x$ increases for $x > 0$.



▲ **Figure 0.5.1**



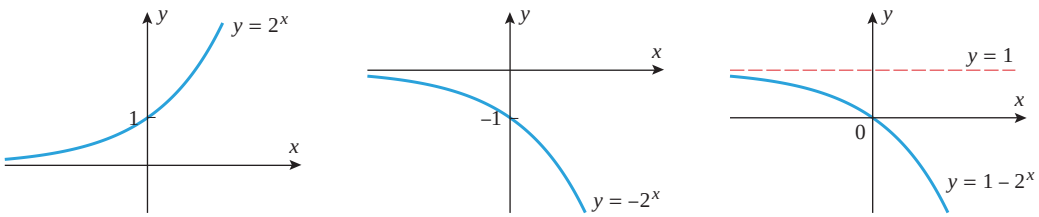
▲ **Figure 0.5.2** The family $y = b^x (b > 0)$

The domain and range of the exponential function $f(x) = b^x$ can also be found by examining Figure 0.5.1:

- If $b > 0$, then $f(x) = b^x$ is defined and has a real value for every real value of $x$, so the natural domain of every exponential function is $(-\infty, +\infty)$.
- If $b > 0$ and $b \neq 1$, then as noted earlier the graph of $y = b^x$ increases indefinitely as it is traversed in one direction and decreases toward zero but never reaches zero as it is traversed in the other direction. This implies that the range of $f(x) = b^x$ is $(0, +\infty)$.*

**▶ Example 1** Sketch the graph of the function $f(x) = 1 - 2^x$ and find its domain and range.

***Solution.*** Start with a graph of $y = 2^x$. Reflect this graph across the $x$-axis to obtain the graph of $y = -2^x$, then translate that graph upward by 1 unit to obtain the graph of $y = 1 - 2^x$ (Figure 0.5.3). The dashed line in the third part of Figure 0.5.3 is a horizontal asymptote for the graph. You should be able to see from the graph that the domain of $f$ is $(-\infty, +\infty)$ and the range is $(-\infty, 1)$. ◀



▲ **Figure 0.5.3**

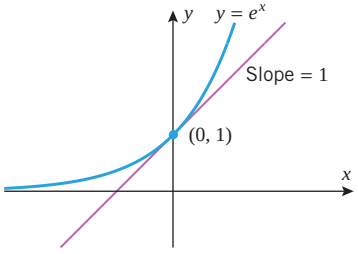
## THE NATURAL EXPONENTIAL FUNCTION

Among all possible bases for exponential functions there is one particular base that plays a special role in calculus. That base, denoted by the letter $e$, is a certain irrational number whose value to six decimal places is

$$e \approx 2.718282 \tag{2}$$

The use of the letter $e$ is in honor of the Swiss mathematician Leonhard Euler (biography on p. 3) who is credited with recognizing the mathematical importance of this constant.

This base is important in calculus because, as we will prove later, $b = e$ is the only base for which the slope of the tangent line** to the curve $y = b^x$ at any point $P$ on the curve is equal to the $y$-coordinate at $P$. Thus, for example, the tangent line to $y = e^x$ at (0, 1) has slope 1 (Figure 0.5.4).



▲ **Figure 0.5.4** The tangent line to the graph of $y = e^x$ at (0, 1) has slope 1.

The function $f(x) = e^x$ is called the ***natural exponential function***. To simplify typography, the natural exponential function is sometimes written as $\exp(x)$, in which case the relationship $e^{x_1+x_2} = e^{x_1}e^{x_2}$ would be expressed as

$$\exp(x_1 + x_2) = \exp(x_1)\exp(x_2)$$

*We are assuming without proof that the graph of $y = b^x$ is a curve without breaks, gaps, or holes.

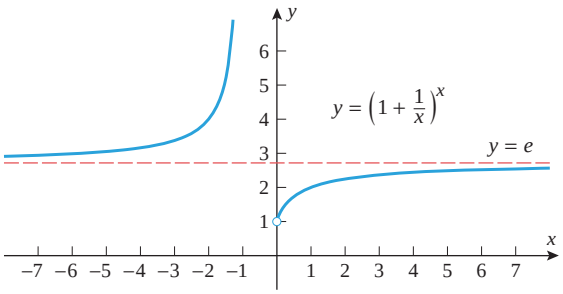
**The precise definition of a tangent line will be discussed later. For now your intuition will suffice.

**TECHNOLOGY MASTERY** Your technology utility should have keys or commands for approximating $e$ and for graphing the natural exponential function. Read your documentation on how to do this and use your utility to confirm (2) and to generate the graphs in Figures 0.5.2 and 0.5.4.

The constant $e$ also arises in the context of the graph of the equation

$$y = \left(1 + \frac{1}{x}\right)^x \tag{3}$$

As shown in Figure 0.5.5, $y = e$ is a horizontal asymptote of this graph. As a result, the value of $e$ can be approximated to any degree of accuracy by evaluating (3) for $x$ sufficiently large in absolute value (Table 0.5.2).



▲ **Figure 0.5.5**

**Table 0.5.2**

APPROXIMATIONS OF $e$ BY $(1 + 1/x)^x$ FOR INCREASING VALUES OF $x$

| $x$ | $1 + \frac{1}{x}$ | $\left(1 + \frac{1}{x}\right)^x$ |
|---|---|---|
| 1 | 2 | $\approx 2.000000$ |
| 10 | 1.1 | 2.593742 |
| 100 | 1.01 | 2.704814 |
| 1000 | 1.001 | 2.716924 |
| 10,000 | 1.0001 | 2.718146 |
| 100,000 | 1.00001 | 2.718268 |
| 1,000,000 | 1.000001 | 2.718280 |

## LOGARITHMIC FUNCTIONS

Recall from algebra that a logarithm is an exponent. More precisely, if $b > 0$ and $b \neq 1$, then for a positive value of $x$ the expression

$$\log_b x$$

(read "the logarithm to the base $b$ of $x$") denotes that exponent to which $b$ must be raised to produce $x$. Thus, for example,

$$\log_{10} 100 = 2, \quad \log_{10}(1/1000) = -3, \quad \log_2 16 = 4, \quad \log_b 1 = 0, \quad \log_b b = 1$$

$10^2 = 100$ $\quad 10^{-3} = 1/1000$ $\quad 2^4 = 16$ $\quad b^0 = 1$ $\quad b^1 = b$

Logarithms with base 10 are called ***common logarithms*** and are often written without explicit reference to the base. Thus, the symbol $\log x$ generally denotes $\log_{10} x$.

We call the function $f(x) = \log_b x$ the ***logarithmic function with base b***.

Logarithmic functions can also be viewed as inverses of exponential functions. To see why this is so, observe from Figure 0.5.1 that if $b > 0$ and $b \neq 1$, then the graph of $f(x) = b^x$ passes the horizontal line test, so $b^x$ has an inverse. We can find a formula for this inverse with $x$ as the independent variable by solving the equation

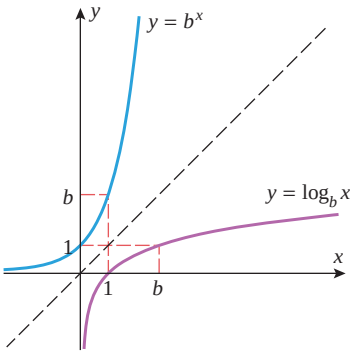
$$x = b^y$$

for $y$ as a function of $x$. But this equation states that $y$ is the logarithm to the base $b$ of $x$, so it can be rewritten as

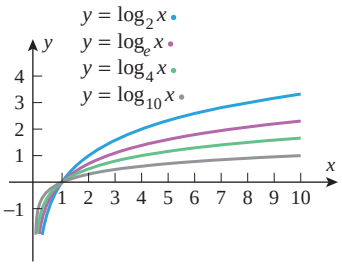
$$y = \log_b x$$

Thus, we have established the following result.

**0.5.1 THEOREM** *If $b > 0$ and $b \neq 1$, then $b^x$ and $\log_b x$ are inverse functions.*



▲ **Figure 0.5.6**



▲ **Figure 0.5.7** The family $y = \log_b x$ $(b > 1)$

**TECHNOLOGY MASTERY**

Use your graphing utility to generate the graphs of $y = \ln x$ and $y = \log x$.

It follows from this theorem that the graphs of $y = b^x$ and $y = \log_b x$ are reflections of one another about the line $y = x$ (see Figure 0.5.6 for the case where $b > 1$). Figure 0.5.7 shows the graphs of $y = \log_b x$ for various values of $b$. Observe that they all pass through the point $(1, 0)$.

The most important logarithms in applications are those with base $e$. These are called ***natural logarithms*** because the function $\log_e x$ is the inverse of the natural exponential function $e^x$. It is standard to denote the natural logarithm of $x$ by $\ln x$ (read "ell en of $x$"), rather than $\log_e x$. For example,

$$\ln 1 = 0, \quad \ln e = 1, \quad \ln 1/e = -1, \quad \ln(e^2) = 2$$

Since $e^0 = 1$ | Since $e^1 = e$ | Since $e^{-1} = 1/e$ | Since $e^2 = e^2$

In general,

$$y = \ln x \quad \text{if and only if} \quad x = e^y$$

As shown in Table 0.5.3, the inverse relationship between $b^x$ and $\log_b x$ produces a correspondence between some basic properties of those functions.

**Table 0.5.3**
CORRESPONDENCE BETWEEN PROPERTIES OF LOGARITHMIC AND EXPONENTIAL FUNCTIONS

| PROPERTY OF $b^x$ | PROPERTY OF $\log_b x$ |
|---|---|
| $b^0 = 1$ | $\log_b 1 = 0$ |
| $b^1 = b$ | $\log_b b = 1$ |
| Range is $(0, +\infty)$ | Domain is $(0, +\infty)$ |
| Domain is $(-\infty, +\infty)$ | Range is $(-\infty, +\infty)$ |
| $x$-axis is a horizontal asymptote | $y$-axis is a vertical asymptote |

It also follows from the cancellation properties of inverse functions [see (3) in Section 0.4] that

$$\begin{aligned} \log_b(b^x) &= x \quad \text{for all real values of } x \\ b^{\log_b x} &= x \quad \text{for } x > 0 \end{aligned} \tag{4}$$

In the special case where $b = e$, these equations become

$$\begin{aligned} \ln(e^x) &= x \quad \text{for all real values of } x \\ e^{\ln x} &= x \quad \text{for } x > 0 \end{aligned} \tag{5}$$

In words, the functions $b^x$ and $\log_b x$ cancel out the effect of one another when composed in either order; for example,

$$\log 10^x = x, \quad 10^{\log x} = x, \quad \ln e^x = x, \quad e^{\ln x} = x, \quad \ln e^5 = 5, \quad e^{\ln \pi} = \pi$$

## SOLVING EQUATIONS INVOLVING EXPONENTIALS AND LOGARITHMS

You should be familiar with the following properties of logarithms from your earlier studies.

**0.5.2 THEOREM** (*Algebraic Properties of Logarithms*) *If $b > 0, b \neq 1, a > 0, c > 0$, and $r$ is any real number, then:*

| | | |
|---|---|---|
| $(a)$ | $\log_b(ac) = \log_b a + \log_b c$ | Product property |
| $(b)$ | $\log_b(a/c) = \log_b a - \log_b c$ | Quotient property |
| $(c)$ | $\log_b(a^r) = r \log_b a$ | Power property |
| $(d)$ | $\log_b(1/c) = -\log_b c$ | Reciprocal property |

**WARNING**

Expressions of the form $\log_b(u + v)$ and $\log_b(u - v)$ have no useful simplifications. In particular,

$$\log_b(u + v) \neq \log_b(u) + \log_b(v)$$
$$\log_b(u - v) \neq \log_b(u) - \log_b(v)$$

These properties are often used to expand a single logarithm into sums, differences, and multiples of other logarithms and, conversely, to condense sums, differences, and multiples of logarithms into a single logarithm. For example,

$$\log \frac{xy^5}{\sqrt{z}} = \log xy^5 - \log \sqrt{z} = \log x + \log y^5 - \log z^{1/2} = \log x + 5 \log y - \tfrac{1}{2} \log z$$

$$5 \log 2 + \log 3 - \log 8 = \log 32 + \log 3 - \log 8 = \log \frac{32 \cdot 3}{8} = \log 12$$

$$\tfrac{1}{3} \ln x - \ln(x^2 - 1) + 2 \ln(x + 3) = \ln x^{1/3} - \ln(x^2 - 1) + \ln(x + 3)^2 = \ln \frac{\sqrt[3]{x}(x + 3)^2}{x^2 - 1}$$

An equation of the form $\log_b x = k$ can be solved for $x$ by rewriting it in the exponential form $x = b^k$, and an equation of the form $b^x = k$ can be solved by rewriting it in the logarithm form $x = \log_b k$. Alternatively, the equation $b^x = k$ can be solved by taking *any* logarithm of both sides (but usually log or ln) and applying part $(c)$ of Theorem 0.5.2. These ideas are illustrated in the following example.

▶ **Example 2** Find $x$ such that

(a) $\log x = \sqrt{2}$ (b) $\ln(x + 1) = 5$ (c) $5^x = 7$

***Solution (a).*** Converting the equation to exponential form yields

$$x = 10^{\sqrt{2}} \approx 25.95$$

***Solution (b).*** Converting the equation to exponential form yields

$$x + 1 = e^5 \quad \text{or} \quad x = e^5 - 1 \approx 147.41$$

***Solution (c).*** Converting the equation to logarithmic form yields

$$x = \log_5 7 \approx 1.21$$

Alternatively, taking the natural logarithm of both sides and using the power property of logarithms yields

$$x \ln 5 = \ln 7 \quad \text{or} \quad x = \frac{\ln 7}{\ln 5} \approx 1.21 \quad \blacktriangleleft$$

Erik Simonsen/Getty Images

*Power to satellites can be supplied by batteries, fuel cells, solar cells, or radioisotope devices.*

▶ **Example 3** A satellite that requires 7 watts of power to operate at full capacity is equipped with a radioisotope power supply whose power output $P$ in watts is given by the equation

$$P = 75e^{-t/125}$$

where $t$ is the time in days that the supply is used. How long can the satellite operate at full capacity?

***Solution.*** The power $P$ will fall to 7 watts when

$$7 = 75e^{-t/125}$$

The solution for $t$ is as follows:

$$\begin{aligned} 7/75 &= e^{-t/125} \\ \ln(7/75) &= \ln(e^{-t/125}) \\ \ln(7/75) &= -t/125 \\ t &= -125\ln(7/75) \approx 296.4 \end{aligned}$$

so the satellite can operate at full capacity for about 296 days. ◀

Here is a more complicated example.

▶ **Example 4** Solve $\dfrac{e^x - e^{-x}}{2} = 1$ for $x$.

***Solution.*** Multiplying both sides of the given equation by 2 yields

$$e^x - e^{-x} = 2$$

or equivalently,

$$e^x - \frac{1}{e^x} = 2$$

Multiplying through by $e^x$ yields

$$e^{2x} - 1 = 2e^x \quad \text{or} \quad e^{2x} - 2e^x - 1 = 0$$

This is really a quadratic equation in disguise, as can be seen by rewriting it in the form

$$\left(e^x\right)^2 - 2e^x - 1 = 0$$

and letting $u = e^x$ to obtain

$$u^2 - 2u - 1 = 0$$

Solving for $u$ by the quadratic formula yields

$$u = \frac{2 \pm \sqrt{4+4}}{2} = \frac{2 \pm \sqrt{8}}{2} = 1 \pm \sqrt{2}$$

or, since $u = e^x$,

$$e^x = 1 \pm \sqrt{2}$$

But $e^x$ cannot be negative, so we discard the negative value $1 - \sqrt{2}$; thus,

$$\begin{aligned} e^x &= 1 + \sqrt{2} \\ \ln e^x &= \ln(1 + \sqrt{2}) \\ x &= \ln(1 + \sqrt{2}) \approx 0.881 \end{aligned}$$ ◀

## CHANGE OF BASE FORMULA FOR LOGARITHMS

Scientific calculators generally have no keys for evaluating logarithms with bases other than 10 or $e$. However, this is not a serious deficiency because it is possible to express a logarithm with any base in terms of logarithms with any other base (see Exercise 42). For example, the following formula expresses a logarithm with base $b$ in terms of natural logarithms:

$$\log_b x = \frac{\ln x}{\ln b} \tag{6}$$

We can derive this result by letting $y = \log_b x$, from which it follows that $b^y = x$. Taking the natural logarithm of both sides of this equation we obtain $y \ln b = \ln x$, from which (6) follows.

▶ **Example 5** Use a calculating utility to evaluate $\log_2 5$ by expressing this logarithm in terms of natural logarithms.

***Solution.*** From (6) we obtain

$$\log_2 5 = \frac{\ln 5}{\ln 2} \approx 2.321928 \quad \blacktriangleleft$$

## LOGARITHMIC SCALES IN SCIENCE AND ENGINEERING

Logarithms are used in science and engineering to deal with quantities whose units vary over an excessively wide range of values. For example, the "loudness" of a sound can be measured by its ***intensity*** $I$ (in watts per square meter), which is related to the energy transmitted by the sound wave—the greater the intensity, the greater the transmitted energy, and the louder the sound is perceived by the human ear. However, intensity units are unwieldy because they vary over an enormous range. For example, a sound at the threshold of human hearing has an intensity of about $10^{-12}\ \mathrm{W/m^2}$, a close whisper has an intensity that is about 100 times the hearing threshold, and a jet engine at 50 meters has an intensity that is about $10{,}000{,}000{,}000{,}000 = 10^{13}$ times the hearing threshold. To see how logarithms can be used to reduce this wide spread, observe that if

$$y = \log x$$

then increasing $x$ by a *factor* of 10 *adds* 1 unit to $y$ since

$$\log 10x = \log 10 + \log x = 1 + y$$

Physicists and engineers take advantage of this property by measuring loudness in terms of the ***sound level*** $\beta$, which is defined by

$$\beta = 10 \log(I/I_0)$$

where $I_0 = 10^{-12}\ \mathrm{W/m^2}$ is a reference intensity close to the threshold of human hearing. The units of $\beta$ are ***decibels*** (dB), named in honor of the telephone inventor Alexander Graham Bell. With this scale of measurement, *multiplying* the intensity $I$ by a factor of 10 *adds* 10 dB to the sound level $\beta$ (verify). This results in a more tractable scale than intensity for measuring sound loudness (Table 0.5.4). Some other familiar logarithmic scales are the ***Richter scale*** used to measure earthquake intensity and the **pH *scale*** used to measure acidity in chemistry, both of which are discussed in the exercises.

**Table 0.5.4**

| $\beta$ (dB) | $I/I_0$ |
|---|---|
| 0 | $10^0 = 1$ |
| 10 | $10^1 = 10$ |
| 20 | $10^2 = 100$ |
| 30 | $10^3 = 1000$ |
| 40 | $10^4 = 10{,}000$ |
| 50 | $10^5 = 100{,}000$ |
| ⋮ | ⋮ |
| 120 | $10^{12} = 1{,}000{,}000{,}000{,}000$ |

Regina Mitchell-Ryall, Tony Gray/NASA/Getty Images

*The roar of a space shuttle near the launchpad would damage your hearing without ear protection.*

**Example 6** A space shuttle taking off generates a sound level of 150 dB near the launchpad. A person exposed to this level of sound would experience severe physical injury. By comparison, a car horn at one meter has a sound level of 110 dB, near the threshold of pain for many people. What is the ratio of sound intensity of a space shuttle takeoff to that of a car horn?

***Solution.*** Let $I_1$ and $\beta_1$ (= 150 dB) denote the sound intensity and sound level of the space shuttle taking off, and let $I_2$ and $\beta_2$ (= 110 dB) denote the sound intensity and sound level of a car horn. Then

$$\begin{aligned} I_1/I_2 &= (I_1/I_0)/(I_2/I_0) \\ \log(I_1/I_2) &= \log(I_1/I_0) - \log(I_2/I_0) \\ 10\log(I_1/I_2) &= 10\log(I_1/I_0) - 10\log(I_2/I_0) = \beta_1 - \beta_2 \\ 10\log(I_1/I_2) &= 150 - 100 = 40 \\ \log(I_1/I_2) &= 4 \end{aligned}$$

Thus, $I_1/I_2 = 10^4$, which tells us that the sound intensity of the space shuttle taking off is 10,000 times greater than a car horn! ◄

## EXPONENTIAL AND LOGARITHMIC GROWTH

The growth patterns of $e^x$ and $\ln x$ illustrated in Table 0.5.5 are worth noting. Both functions increase as $x$ increases, but they increase in dramatically different ways—the value of $e^x$ increases extremely rapidly and that of $\ln x$ increases extremely slowly. For example, the value of $e^x$ at $x = 10$ is over 22,000, but at $x = 1000$ the value of $\ln x$ has not even reached 7.

**Table 0.5.5**

| $x$ | $e^x$ | $\ln x$ |
|---|---|---|
| 1 | 2.72 | 0.00 |
| 2 | 7.39 | 0.69 |
| 3 | 20.09 | 1.10 |
| 4 | 54.60 | 1.39 |
| 5 | 148.41 | 1.61 |
| 6 | 403.43 | 1.79 |
| 7 | 1096.63 | 1.95 |
| 8 | 2980.96 | 2.08 |
| 9 | 8103.08 | 2.20 |
| 10 | 22026.47 | 2.30 |
| 100 | $2.69 \times 10^{43}$ | 4.61 |
| 1000 | $1.97 \times 10^{434}$ | 6.91 |

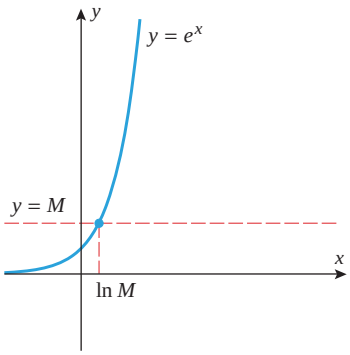
A function $f$ is said to ***increase without bound*** as $x$ increases if the values of $f(x)$ eventually exceed any specified positive number $M$ (no matter how large) as $x$ increases indefinitely. Table 0.5.5 strongly suggests that $f(x) = e^x$ increases without bound, which is consistent with the fact that the range of this function is $(0, +\infty)$. Indeed, if we choose any positive number $M$, then we will have $e^x = M$ when $x = \ln M$, and since the values of $e^x$ increase as $x$ increases, we will have

$$e^x > M \quad \text{if} \quad x > \ln M$$

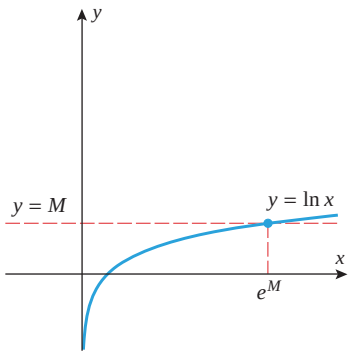
(Figure 0.5.8). It is not clear from Table 0.5.5 whether $\ln x$ increases without bound as $x$ increases because the values grow so slowly, but we know this to be so since the range of this function is $(-\infty, +\infty)$. To see this algebraically, let $M$ be any positive number. We will have $\ln x = M$ when $x = e^M$, and since the values of $\ln x$ increase as $x$ increases, we will have

$$\ln x > M \quad \text{if} \quad x > e^M$$

(Figure 0.5.9).



▲ **Figure 0.5.8** The value of $y = e^x$ will exceed an arbitrary positive value of $M$ when $x > \ln M$.



▲ **Figure 0.5.9** The value of $y = \ln x$ will exceed an arbitrary positive value of $M$ when $x > e^M$.

## ✔ QUICK CHECK EXERCISES 0.5 (See page 63 for answers.)

1. The function $y = \left(\frac{1}{2}\right)^x$ has domain _____ and range _____.
2. The function $y = \ln(1 - x)$ has domain _____ and range _____.
3. Express as a power of 4:
   (a) 1 (b) 2 (c) $\frac{1}{16}$ (d) $\sqrt{8}$ (e) 5.
4. Solve each equation for $x$.
   (a) $e^x = \frac{1}{2}$ (b) $10^{3x} = 1{,}000{,}000$
   (c) $7e^{3x} = 56$
5. Solve each equation for $x$.
   (a) $\ln x = 3$ (b) $\log(x - 1) = 2$
   (c) $2\log x - \log(x + 1) = \log 4 - \log 3$

## EXERCISE SET 0.5 Graphing Utility

**1–2** Simplify the expression without using a calculating utility. ■

1. (a) $-8^{2/3}$ (b) $(-8)^{2/3}$ (c) $8^{-2/3}$
2. (a) $2^{-4}$ (b) $4^{1.5}$ (c) $9^{-0.5}$

**3–4** Use a calculating utility to approximate the expression. Round your answer to four decimal places. ■

3. (a) $2^{1.57}$ (b) $5^{-2.1}$
4. (a) $\sqrt[5]{24}$ (b) $\sqrt[8]{0.6}$

**5–6** Find the exact value of the expression without using a calculating utility. ■

5. (a) $\log_2 16$ (b) $\log_2\left(\frac{1}{32}\right)$
   (c) $\log_4 4$ (d) $\log_9 3$
6. (a) $\log_{10}(0.001)$ (b) $\log_{10}(10^4)$
   (c) $\ln(e^3)$ (d) $\ln(\sqrt{e})$

**7–8** Use a calculating utility to approximate the expression. Round your answer to four decimal places. ■

7. (a) $\log 23.2$ (b) $\ln 0.74$
8. (a) $\log 0.3$ (b) $\ln \pi$

**9–10** Use the logarithm properties in Theorem 0.5.2 to rewrite the expression in terms of $r$, $s$, and $t$, where $r = \ln a$, $s = \ln b$, and $t = \ln c$. ■

9. (a) $\ln a^2\sqrt{bc}$ (b) $\ln \dfrac{b}{a^3 c}$
10. (a) $\ln \dfrac{\sqrt[3]{c}}{ab}$ (b) $\ln \sqrt{\dfrac{ab^3}{c^2}}$

**11–12** Expand the logarithm in terms of sums, differences, and multiples of simpler logarithms. ■

11. (a) $\log(10x\sqrt{x-3})$ (b) $\ln \dfrac{x^2 \sin^3 x}{\sqrt{x^2+1}}$
12. (a) $\log \dfrac{\sqrt[3]{x+2}}{\cos 5x}$ (b) $\ln \sqrt{\dfrac{x^2+1}{x^3+5}}$

**13–15** Rewrite the expression as a single logarithm. ■

13. $4\log 2 - \log 3 + \log 16$
14. $\frac{1}{2}\log x - 3\log(\sin 2x) + 2$
15. $2\ln(x+1) + \frac{1}{3}\ln x - \ln(\cos x)$

**16–23** Solve for $x$ without using a calculating utility. ■

16. $\log_{10}(1 + x) = 3$
17. $\log_{10}(\sqrt{x}) = -1$
18. $\ln(x^2) = 4$
19. $\ln(1/x) = -2$
20. $\log_3(3^x) = 7$
21. $\log_5(5^{2x}) = 8$
22. $\ln 4x - 3\ln(x^2) = \ln 2$
23. $\ln(1/x) + \ln(2x^3) = \ln 3$

**24–29** Solve for $x$ without using a calculating utility. Use the natural logarithm anywhere that logarithms are needed. ■

24. $3^x = 2$
25. $5^{-2x} = 3$
26. $3e^{-2x} = 5$
27. $2e^{3x} = 7$
28. $e^x - 2xe^x = 0$
29. $xe^{-x} + 2e^{-x} = 0$
30. Solve $e^{-2x} - 3e^{-x} = -2$ for $x$ without using a calculating utility. [*Hint:* Rewrite the equation as a quadratic equation in $u = e^{-x}$.]

### FOCUS ON CONCEPTS

**31–34** In each part, identify the domain and range of the function, and then sketch the graph of the function without using a graphing utility. ■

31. (a) $f(x) = \left(\frac{1}{2}\right)^{x-1} - 1$ (b) $g(x) = \ln|x|$
32. (a) $f(x) = 1 + \ln(x - 2)$ (b) $g(x) = 3 + e^{x-2}$
33. (a) $f(x) = \ln(x^2)$ (b) $g(x) = e^{-x^2}$
34. (a) $f(x) = 1 - e^{-x+1}$ (b) $g(x) = 3\ln\sqrt[3]{x-1}$

**35–38 True–False** Determine whether the statement is true or false. Explain your answer. ■

35. The function $y = x^3$ is an exponential function.
36. The graph of the exponential function with base $b$ passes through the point (0, 1).
37. The natural logarithm function is the logarithmic function with base $e$.

**38.** The domain of a logarithmic function is the interval $x > 1$.

**39.** Use a calculating utility and the change of base formula (6) to find the values of $\log_2 7.35$ and $\log_5 0.6$, rounded to four decimal places.

**40–41** Graph the functions on the same screen of a graphing utility. [Use the change of base formula (6), where needed.] ■

**40.** $\ln x,\ e^x,\ \log x,\ 10^x$

**41.** $\log_2 x,\ \ln x,\ \log_5 x,\ \log x$

**42.** (a) Derive the general change of base formula

$$\log_b x = \frac{\log_a x}{\log_a b}$$

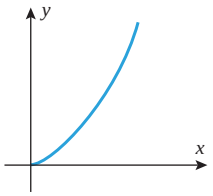
(b) Use the result in part (a) to find the exact value of $(\log_2 81)(\log_3 32)$ without using a calculating utility.

**43.** Use a graphing utility to estimate the two points of intersection of the graphs of $y = 1.3^x$ and $y = \log_{1.3} x$.

**44.** Use a graphing utility to estimate the two points of intersection of the graphs of $y = 0.6^{(x^2)}$ and $y = \log_{0.6}(x^2)$.

**FOCUS ON CONCEPTS**

**45.** (a) Is the curve in the accompanying figure the graph of an exponential function? Explain your reasoning.
(b) Find the equation of an exponential function that passes through the point $(4, 2)$.
(c) Find the equation of an exponential function that passes through the point $\left(2, \frac{1}{4}\right)$.
(d) Use a graphing utility to generate the graph of an exponential function that passes through the point $(2, 5)$.



◀ **Figure Ex-45**

**46.** (a) Make a conjecture about the general shape of the graph of $y = \log(\log x)$, and sketch the graph of this equation and $y = \log x$ in the same coordinate system.
(b) Check your work in part (a) with a graphing utility.

**47.** Find the fallacy in the following "proof" that $\frac{1}{8} > \frac{1}{4}$. Multiply both sides of the inequality $3 > 2$ by $\log \frac{1}{2}$ to get

$$3 \log \tfrac{1}{2} > 2 \log \tfrac{1}{2}$$
$$\log \left(\tfrac{1}{2}\right)^3 > \log \left(\tfrac{1}{2}\right)^2$$
$$\log \tfrac{1}{8} > \log \tfrac{1}{4}$$
$$\tfrac{1}{8} > \tfrac{1}{4}$$

**48.** Prove the four algebraic properties of logarithms in Theorem 0.5.2.

**49.** If equipment in the satellite of Example 3 requires 15 watts to operate correctly, what is the operational lifetime of the power supply?

**50.** The equation $Q = 12e^{-0.055t}$ gives the mass $Q$ in grams of radioactive potassium-42 that will remain from some initial quantity after $t$ hours of radioactive decay.
(a) How many grams were there initially?
(b) How many grams remain after 4 hours?
(c) How long will it take to reduce the amount of radioactive potassium-42 to half of the initial amount?

**51.** The acidity of a substance is measured by its pH value, which is defined by the formula

$$\text{pH} = -\log[H^+]$$

where the symbol $[H^+]$ denotes the concentration of hydrogen ions measured in moles per liter. Distilled water has a pH of 7; a substance is called *acidic* if it has pH $< 7$ and *basic* if it has pH $> 7$. Find the pH of each of the following substances and state whether it is acidic or basic.

| | SUBSTANCE | $[H^+]$ |
|---|---|---|
| (a) | Arterial blood | $3.9 \times 10^{-8}$ mol/L |
| (b) | Tomatoes | $6.3 \times 10^{-5}$ mol/L |
| (c) | Milk | $4.0 \times 10^{-7}$ mol/L |
| (d) | Coffee | $1.2 \times 10^{-6}$ mol/L |

**52.** Use the definition of pH in Exercise 51 to find $[H^+]$ in a solution having a pH equal to
(a) 2.44 (b) 8.06.

**53.** The perceived loudness $\beta$ of a sound in decibels (dB) is related to its intensity $I$ in watts per square meter ($\text{W/m}^2$) by the equation

$$\beta = 10 \log(I/I_0)$$

where $I_0 = 10^{-12}\ \text{W/m}^2$. Damage to the average ear occurs at 90 dB or greater. Find the decibel level of each of the following sounds and state whether it will cause ear damage.

| | SOUND | $I$ |
|---|---|---|
| (a) | Jet aircraft (from 50 ft) | $1.0 \times 10^2\ \text{W/m}^2$ |
| (b) | Amplified rock music | $1.0\ \text{W/m}^2$ |
| (c) | Garbage disposal | $1.0 \times 10^{-4}\ \text{W/m}^2$ |
| (d) | TV (mid volume from 10 ft) | $3.2 \times 10^{-5}\ \text{W/m}^2$ |

**54–56** Use the definition of the decibel level of a sound (see Exercise 53). ■

**54.** If one sound is three times as intense as another, how much greater is its decibel level?

**55.** According to one source, the noise inside a moving automobile is about 70 dB, whereas an electric blender generates 93 dB. Find the ratio of the intensity of the noise of the blender to that of the automobile.

**56.** Suppose that the intensity level of an echo is $\frac{2}{3}$ the intensity level of the original sound. If each echo results in another echo, how many echoes will be heard from a 120 dB sound given that the average human ear can hear a sound as low as 10 dB?

**57.** On the ***Richter scale***, the magnitude $M$ of an earthquake is related to the released energy $E$ in joules (J) by the equation

$$\log E = 4.4 + 1.5M$$

(a) Find the energy $E$ of the 1906 San Francisco earthquake that registered $M = 8.2$ on the Richter scale.
(b) If the released energy of one earthquake is 10 times that of another, how much greater is its magnitude on the Richter scale?

**58.** Suppose that the magnitudes of two earthquakes differ by 1 on the Richter scale. Find the ratio of the released energy of the larger earthquake to that of the smaller earthquake. [*Note:* See Exercise 57 for terminology.]

## ✔ QUICK CHECK ANSWERS 0.5

**1.** $(-\infty, +\infty)$; $(0, +\infty)$ **2.** $(-\infty, 1)$; $(-\infty, +\infty)$ **3.** (a) $4^0$ (b) $4^{1/2}$ (c) $4^{-2}$ (d) $4^{3/4}$ (e) $4^{\log_4 5}$ **4.** (a) $\ln \frac{1}{2} = -\ln 2$ (b) 2 (c) $\ln 2$ **5.** (a) $e^3$ (b) 101 (c) 2

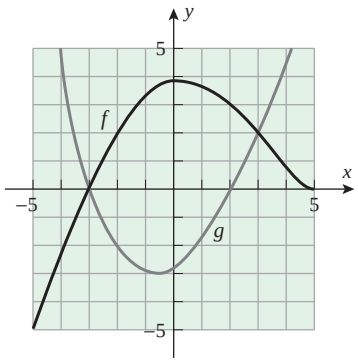
## CHAPTER 0 REVIEW EXERCISES

Graphing Utility

**1.** Sketch the graph of the function

$$f(x) = \begin{cases} -1, & x \le -5 \\ \sqrt{25 - x^2}, & -5 < x < 5 \\ x - 5, & x \ge 5 \end{cases}$$

**2.** Use the graphs of the functions $f$ and $g$ in the accompanying figure to solve the following problems.
(a) Find the values of $f(-2)$ and $g(3)$.
(b) For what values of $x$ is $f(x) = g(x)$?
(c) For what values of $x$ is $f(x) < 2$?
(d) What are the domain and range of $f$?
(e) What are the domain and range of $g$?
(f) Find the zeros of $f$ and $g$.



◀ **Figure Ex-2**

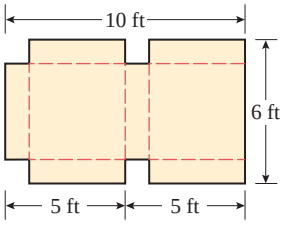
**3.** A glass filled with water that has a temperature of 40°F is placed in a room in which the temperature is a constant 70°F. Sketch a rough graph that reasonably describes the temperature of the water in the glass as a function of the elapsed time.

**4.** You want to paint the top of a circular table. Find a formula that expresses the amount of paint required as a function of the radius, and discuss all of the assumptions you have made in finding the formula.

**5.** A rectangular storage container with an open top and a square base has a volume of 8 cubic meters. Material for the base costs \$5 per square meter and material for the sides \$2 per square meter.
(a) Find a formula that expresses the total cost of materials as a function of the length of a side of the base.
(b) What is the domain of the cost function obtained in part (a)?

**6.** A ball of radius 3 inches is coated uniformly with plastic.
(a) Express the volume of the plastic as a function of its thickness.
(b) What is the domain of the volume function obtained in part (a)?

**7.** A box with a closed top is to be made from a 6 ft by 10 ft piece of cardboard by cutting out four squares of equal size (see the accompanying figure), folding along the dashed lines, and tucking the two extra flaps inside.
(a) Find a formula that expresses the volume of the box as a function of the length of the sides of the cut-out squares.
(b) Find an inequality that specifies the domain of the function in part (a).
(c) Use the graph of the volume function to estimate the dimensions of the box of largest volume.



◀ **Figure Ex-7**

**8.** Let $C$ denote the graph of $y = 1/x$, $x > 0$.
(a) Express the distance between the point $P(1, 0)$ and a point $Q$ on $C$ as a function of the $x$-coordinate of $Q$.
(b) What is the domain of the distance function obtained in part (a)?

(cont.)

(c) Use the graph of the distance function obtained in part (a) to estimate the point $Q$ on $C$ that is closest to the point $P$.

**9.** Sketch the graph of the equation $x^2 - 4y^2 = 0$.

**10.** Generate the graph of $f(x) = x^4 - 24x^3 - 25x^2$ in two different viewing windows, each of which illustrates a different property of $f$. Identify each viewing window and a characteristic of the graph of $f$ that is illustrated well in the window.

**11.** Complete the following table.

| $x$ | $-4$ | $-3$ | $-2$ | $-1$ | $0$ | $1$ | $2$ | $3$ | $4$ |
|---|---|---|---|---|---|---|---|---|---|
| $f(x)$ | 0 | $-1$ | 2 | 1 | 3 | $-2$ | $-3$ | 4 | $-4$ |
| $g(x)$ | 3 | 2 | 1 | $-3$ | $-1$ | $-4$ | 4 | $-2$ | 0 |
| $(f \circ g)(x)$ | | | | | | | | | |
| $(g \circ f)(x)$ | | | | | | | | | |

▲ **Table Ex-11**

**12.** Let $f(x) = -x^2$ and $g(x) = 1/\sqrt{x}$. Find formulas for $f \circ g$ and $g \circ f$ and state the domain of each composition.

**13.** Given that $f(x) = x^2 + 1$ and $g(x) = 3x + 2$, find all values of $x$ such that $f(g(x)) = g(f(x))$.

**14.** Let $f(x) = (2x - 1)/(x + 1)$ and $g(x) = 1/(x - 1)$.
(a) Find $f(g(x))$.
(b) Is the natural domain of the function $h(x) = (3 - x)/x$ the same as the domain of $f \circ g$? Explain.

**15.** Given that

$$f(x) = \frac{x}{x-1}, \quad g(x) = \frac{1}{x}, \quad h(x) = x^2 - 1$$

find a formula for $f \circ g \circ h$ and state the domain of this composition.

**16.** Given that $f(x) = 2x + 1$ and $h(x) = 2x^2 + 4x + 1$, find a function $g$ such that $f(g(x)) = h(x)$.

**17.** In each part, classify the function as even, odd, or neither.
(a) $x^2 \sin x$ (b) $\sin^2 x$ (c) $x + x^2$ (d) $\sin x \tan x$

**18.** (a) Write an equation for the graph that is obtained by reflecting the graph of $y = |x - 1|$ about the $y$-axis, then stretching that graph vertically by a factor of 2, then translating that graph down 3 units, and then reflecting that graph about the $x$-axis.
(b) Sketch the original graph and the final graph.

**19.** In each part, describe the family of curves.
(a) $(x - a)^2 + (y - a^2)^2 = 1$
(b) $y = a + (x - 2a)^2$

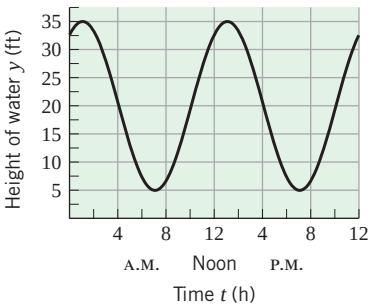
**20.** Find an equation for a parabola that passes through the points $(2, 0)$, $(8, 18)$, and $(-8, 18)$.

**21.** Suppose that the expected low temperature in Anchorage, Alaska (in °F), is modeled by the equation

$$T = 50 \sin \frac{2\pi}{365}(t - 101) + 25$$

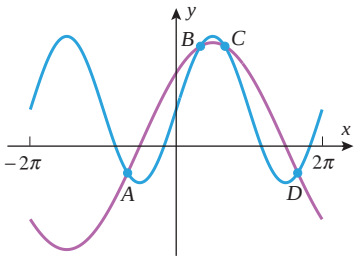
where $t$ is in days and $t = 0$ corresponds to January 1.
(a) Sketch the graph of $T$ versus $t$ for $0 \le t \le 365$.
(b) Use the model to predict when the coldest day of the year will occur.
(c) Based on this model, how many days during the year would you expect the temperature to be below 0°F?

**22.** The accompanying figure shows a model for the tide variation in an inlet to San Francisco Bay during a 24-hour period. Find an equation of the form $y = y_0 + y_1 \sin(at + b)$ for the model, assuming that $t = 0$ corresponds to midnight.



◀ **Figure Ex-22**

**23.** The accompanying figure shows the graphs of the equations $y = 1 + 2 \sin x$ and $y = 2 \sin(x/2) + 2 \cos(x/2)$ for $-2\pi \le x \le 2\pi$. Without the aid of a calculator, label each curve by its equation, and find the coordinates of the points $A$, $B$, $C$, and $D$. Explain your reasoning.



◀ **Figure Ex-23**

**24.** The electrical resistance $R$ in ohms (Ω) for a pure metal wire is related to its temperature $T$ in °C by the formula

$$R = R_0(1 + kT)$$

in which $R_0$ and $k$ are positive constants.
(a) Make a hand-drawn sketch of the graph of $R$ versus $T$, and explain the geometric significance of $R_0$ and $k$ for your graph.
(b) In theory, the resistance $R$ of a pure metal wire drops to zero when the temperature reaches absolute zero ($T = -273$°C). What information does this give you about $k$?
(c) A tungsten bulb filament has a resistance of 1.1 Ω at a temperature of 20°C. What information does this give you about $R_0$ for the filament? *(cont.)*

(d) At what temperature will the tungsten filament have a resistance of 1.5 Ω?

**25.** (a) State conditions under which two functions, $f$ and $g$, will be inverses, and give several examples of such functions.
(b) In words, what is the relationship between the graphs of $y = f(x)$ and $y = g(x)$ when $f$ and $g$ are inverse functions?
(c) What is the relationship between the domains and ranges of inverse functions $f$ and $g$?
(d) What condition must be satisfied for a function $f$ to have an inverse? Give some examples of functions that do not have inverses.

**26.** (a) State the restrictions on the domains of $\sin x$, $\cos x$, $\tan x$, and $\sec x$ that are imposed to make those functions one-to-one in the definitions of $\sin^{-1} x$, $\cos^{-1} x$, $\tan^{-1} x$, and $\sec^{-1} x$.
(b) Sketch the graphs of the restricted trigonometric functions in part (a) and their inverses.

**27.** In each part, find $f^{-1}(x)$ if the inverse exists.
(a) $f(x) = 8x^3 - 1$ (b) $f(x) = x^2 - 2x + 1$
(c) $f(x) = (e^x)^2 + 1$ (d) $f(x) = (x + 2)/(x - 1)$
(e) $f(x) = \sin\left(\dfrac{1 - 2x}{x}\right), \quad \dfrac{2}{4 + \pi} \le x \le \dfrac{2}{4 - \pi}$
(f) $f(x) = \dfrac{1}{1 + 3\tan^{-1} x}$

**28.** Let $f(x) = (ax + b)/(cx + d)$. What conditions on $a$, $b$, $c$, and $d$ guarantee that $f^{-1}$ exists? Find $f^{-1}(x)$.

**29.** In each part, find the exact numerical value of the given expression.
(a) $\cos[\cos^{-1}(4/5) + \sin^{-1}(5/13)]$
(b) $\sin[\sin^{-1}(4/5) + \cos^{-1}(5/13)]$

**30.** In each part, sketch the graph, and check your work with a graphing utility.
(a) $f(x) = 3\sin^{-1}(x/2)$
(b) $f(x) = \cos^{-1} x - \pi/2$
(c) $f(x) = 2\tan^{-1}(-3x)$
(d) $f(x) = \cos^{-1} x + \sin^{-1} x$

**31.** Suppose that the graph of $y = \log x$ is drawn with equal scales of 1 inch per unit in both the $x$- and $y$-directions. If a bug wants to walk along the graph until it reaches a height of 5 ft above the $x$-axis, how many miles to the right of the origin will it have to travel?

**32.** Suppose that the graph of $y = 10^x$ is drawn with equal scales of 1 inch per unit in both the $x$- and $y$-directions. If a bug wants to walk along the graph until it reaches a height of 100 mi above the $x$-axis, how many feet to the right of the origin will it have to travel?

**33.** Express the following function as a rational function of $x$:

$$3\ln\left(e^{2x}(e^x)^3\right) + 2\exp(\ln 1)$$

**34.** Suppose that $y = Ce^{kt}$, where $C$ and $k$ are constants, and let $Y = \ln y$. Show that the graph of $Y$ versus $t$ is a line, and state its slope and $Y$-intercept.

**35.** (a) Sketch the curves $y = \pm e^{-x/2}$ and $y = e^{-x/2}\sin 2x$ for $-\pi/2 \le x \le 3\pi/2$ in the same coordinate system, and check your work using a graphing utility.
(b) Find all $x$-intercepts of the curve $y = e^{-x/2}\sin 2x$ in the stated interval, and find the $x$-coordinates of all points where this curve intersects the curves $y = \pm e^{-x/2}$.

**36.** Suppose that a package of medical supplies is dropped from a helicopter straight down by parachute into a remote area. The velocity $v$ (in feet per second) of the package $t$ seconds after it is released is given by $v = 24.61(1 - e^{-1.3t})$.
(a) Graph $v$ versus $t$.
(b) Show that the graph has a horizontal asymptote $v = c$.
(c) The constant $c$ is called the ***terminal velocity***. Explain what the terminal velocity means in practical terms.
(d) Can the package actually reach its terminal velocity? Explain.
(e) How long does it take for the package to reach 98% of its terminal velocity?

**37.** A breeding group of 20 bighorn sheep is released in a protected area in Colorado. It is expected that with careful management the number of sheep, $N$, after $t$ years will be given by the formula

$$N = \frac{220}{1 + 10(0.83^t)}$$

and that the sheep population will be able to maintain itself without further supervision once the population reaches a size of 80.
(a) Graph $N$ versus $t$.
(b) How many years must the state of Colorado maintain a program to care for the sheep?
(c) How many bighorn sheep can the environment in the protected area support? [*Hint:* Examine the graph of $N$ versus $t$ for large values of $t$.]

**38.** An oven is preheated and then remains at a constant temperature. A potato is placed in the oven to bake. Suppose that the temperature $T$ (in °F) of the potato $t$ minutes later is given by $T = 400 - 325(0.97^t)$. The potato will be considered done when its temperature is anywhere between 260°F and 280°F.
(a) During what interval of time would the potato be considered done?
(b) How long does it take for the difference between the potato and oven temperatures to be cut in half?

**39.** (a) Show that the graphs of $y = \ln x$ and $y = x^{0.2}$ intersect.
(b) Approximate the solution(s) of the equation $\ln x = x^{0.2}$ to three decimal places.

**40.** (a) Show that for $x > 0$ and $k \ne 0$ the equations

$$x^k = e^x \quad \text{and} \quad \frac{\ln x}{x} = \frac{1}{k}$$

have the same solutions. *(cont.)*

(b) Use the graph of $y = (\ln x)/x$ to determine the values of $k$ for which the equation $x^k = e^x$ has two distinct positive solutions.
(c) Estimate the positive solution(s) of $x^8 = e^x$.

**41.** Consider $f(x) = x^2 \tan x + \ln x$, $0 < x < \pi/2$.
(a) Explain why $f$ is one-to-one.
(b) Use a graphing utility to generate the graph of $f$. Then sketch the graphs of $f$ and $f^{-1}$ together. What are the asymptotes for each graph?

# 1 LIMITS AND CONTINUITY

Joe McBride/Stone/Getty Images

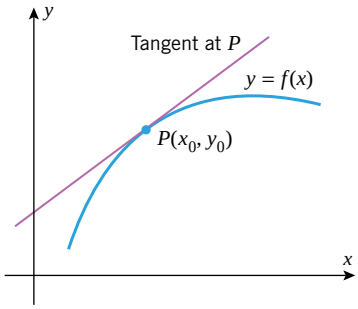
*Air resistance prevents the velocity of a skydiver from increasing indefinitely. The velocity approaches a limit, called the "terminal velocity."*

The development of calculus in the seventeenth century by Newton and Leibniz provided scientists with their first real understanding of what is meant by an "instantaneous rate of change" such as velocity and acceleration. Once the idea was understood conceptually, efficient computational methods followed, and science took a quantum leap forward. The fundamental building block on which rates of change rest is the concept of a "limit," an idea that is so important that all other calculus concepts are now based on it.

In this chapter we will develop the concept of a limit in stages, proceeding from an informal, intuitive notion to a precise mathematical definition. We will also develop theorems and procedures for calculating limits, and we will conclude the chapter by using the limits to study "continuous" curves.

## 1.1 LIMITS (AN INTUITIVE APPROACH)

*The concept of a "limit" is the fundamental building block on which all calculus concepts are based. In this section we will study limits informally, with the goal of developing an intuitive feel for the basic ideas. In the next three sections we will focus on computational methods and precise definitions.*



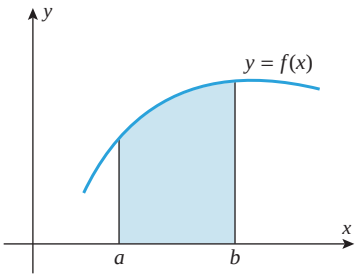
▲ **Figure 1.1.1**

Many of the ideas of calculus originated with the following two geometric problems:

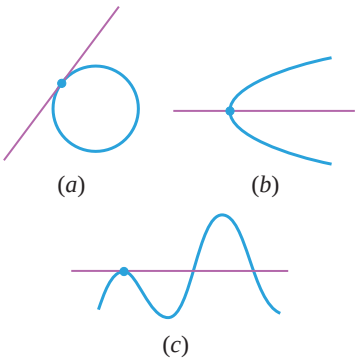
**THE TANGENT LINE PROBLEM** Given a function $f$ and a point $P(x_0, y_0)$ on its graph, find an equation of the line that is tangent to the graph at $P$ (Figure 1.1.1).

**THE AREA PROBLEM** Given a function $f$, find the area between the graph of $f$ and an interval $[a, b]$ on the $x$-axis (Figure 1.1.2).

Traditionally, that portion of calculus arising from the tangent line problem is called ***differential calculus*** and that arising from the area problem is called ***integral calculus***. However, we will see later that the tangent line and area problems are so closely related that the distinction between differential and integral calculus is somewhat artificial.



▲ Figure 1.1.2

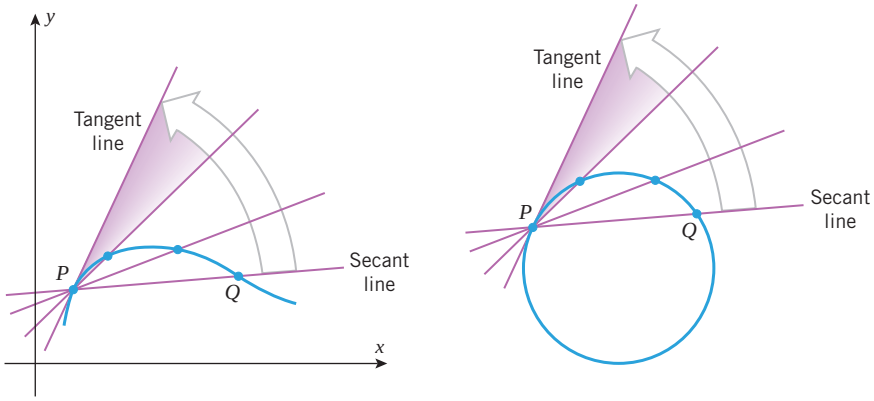


▲ Figure 1.1.3

## TANGENT LINES AND LIMITS

In plane geometry, a line is called *tangent* to a circle if it meets the circle at precisely one point (Figure 1.1.3*a*). Although this definition is adequate for circles, it is not appropriate for more general curves. For example, in Figure 1.1.3*b*, the line meets the curve exactly once but is obviously not what we would regard to be a tangent line; and in Figure 1.1.3*c*, the line appears to be tangent to the curve, yet it intersects the curve more than once.

To obtain a definition of a tangent line that applies to curves other than circles, we must view tangent lines another way. For this purpose, suppose that we are interested in the tangent line at a point $P$ on a curve in the $xy$-plane and that $Q$ is any point that lies on the curve and is different from $P$. The line through $P$ and $Q$ is called a ***secant line*** for the curve at $P$. Intuition suggests that if we move the point $Q$ along the curve toward $P$, then the secant line will rotate toward a *limiting position*. The line in this limiting position is what we will consider to be the ***tangent line*** at $P$ (Figure 1.1.4*a*). As suggested by Figure 1.1.4*b*, this new concept of a tangent line coincides with the traditional concept when applied to circles.



▶ Figure 1.1.4

▶ **Example 1** Find an equation for the tangent line to the parabola $y = x^2$ at the point $P(1, 1)$.

***Solution.*** If we can find the slope $m_{\text{tan}}$ of the tangent line at $P$, then we can use the point $P$ and the point-slope formula for a line (Web Appendix G) to write the equation of the tangent line as

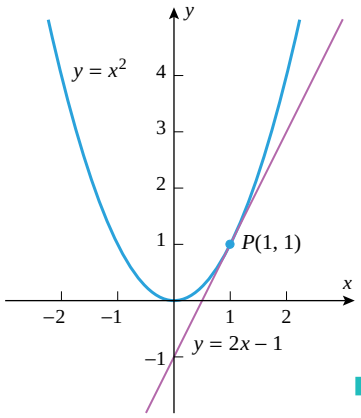
$$y - 1 = m_{\text{tan}}(x - 1) \tag{1}$$

To find the slope $m_{\text{tan}}$, consider the secant line through $P$ and a point $Q(x, x^2)$ on the parabola that is distinct from $P$. The slope $m_{\text{sec}}$ of this secant line is

$$m_{\text{sec}} = \frac{x^2 - 1}{x - 1} \tag{2}$$

Why are we requiring that $P$ and $Q$ be distinct?

Figure 1.1.4*a* suggests that if we now let $Q$ move along the parabola, getting closer and closer to $P$, then the limiting position of the secant line through $P$ and $Q$ will coincide with that of the tangent line at $P$. This in turn suggests that the value of $m_{\text{sec}}$ will get closer and closer to the value of $m_{\text{tan}}$ as $P$ moves toward $Q$ along the curve. However, to say that $Q(x, x^2)$ gets closer and closer to $P(1, 1)$ is algebraically equivalent to saying that $x$ gets closer and closer to 1. Thus, the problem of finding $m_{\text{tan}}$ reduces to finding the "limiting value" of $m_{\text{sec}}$ in Formula (2) as $x$ gets closer and closer to 1 (but with $x \neq 1$ to ensure that $P$ and $Q$ remain distinct).



▲ **Figure 1.1.5**

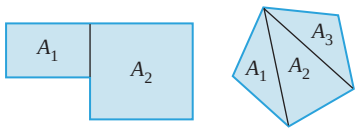
We can rewrite (2) as

$$m_{\text{sec}} = \frac{x^2 - 1}{x - 1} = \frac{(x - 1)(x + 1)}{(x - 1)} = x + 1$$

where the cancellation of the factor $(x - 1)$ is allowed because $x \neq 1$. It is now evident that $m_{\text{sec}}$ gets closer and closer to 2 as $x$ gets closer and closer to 1. Thus, $m_{\text{tan}} = 2$ and (1) implies that the equation of the tangent line is

$$y - 1 = 2(x - 1) \quad \text{or equivalently} \quad y = 2x - 1$$

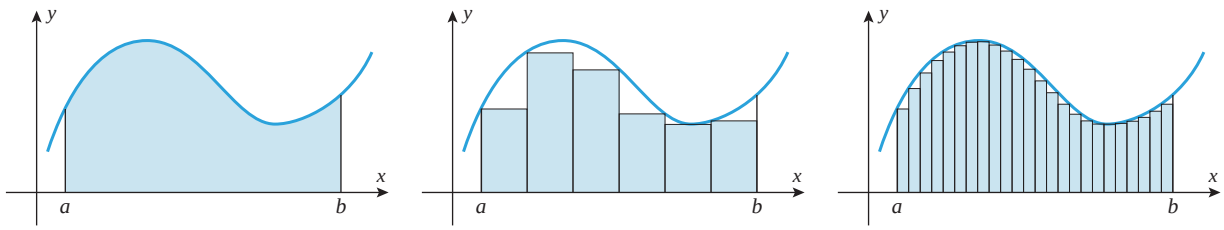
Figure 1.1.5 shows the graph of $y = x^2$ and this tangent line. ◀



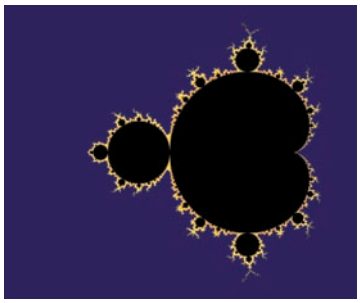
▲ **Figure 1.1.6**

## AREAS AND LIMITS

Just as the general notion of a tangent line leads to the concept of *limit*, so does the general notion of area. For plane regions with straight-line boundaries, areas can often be calculated by subdividing the region into rectangles or triangles and adding the areas of the constituent parts (Figure 1.1.6). However, for regions with curved boundaries, such as that in Figure 1.1.7*a*, a more general approach is needed. One such approach is to begin by approximating the area of the region by inscribing a number of rectangles of equal width under the curve and adding the areas of these rectangles (Figure 1.1.7*b*). Intuition suggests that if we repeat that approximation process using more and more rectangles, then the rectangles will tend to fill in the gaps under the curve, and the approximations will get closer and closer to the exact area under the curve (Figure 1.1.7*c*). This suggests that we can define the area under the curve to be the limiting value of these approximations. This idea will be considered in detail later, but the point to note here is that once again the concept of a limit comes into play.



▲ **Figure 1.1.7**



© James Oakley/Alamy

*This figure shows a region called the* ***Mandelbrot Set****. It illustrates how complicated a region in the plane can be and why the notion of area requires careful definition.*

## DECIMALS AND LIMITS

Limits also arise in the familiar context of decimals. For example, the decimal expansion of the fraction $\frac{1}{3}$ is

$$\frac{1}{3} = 0.33333\ldots \tag{3}$$

in which the dots indicate that the digit 3 repeats indefinitely. Although you may not have thought about decimals in this way, we can write (3) as

$$\frac{1}{3} = 0.33333\ldots = 0.3 + 0.03 + 0.003 + 0.0003 + 0.00003 + \cdots \tag{4}$$

which is a sum with "infinitely many" terms. As we will discuss in more detail later, we interpret (4) to mean that the succession of finite sums

$$0.3, \quad 0.3 + 0.03, \quad 0.3 + 0.03 + 0.003, \quad 0.3 + 0.03 + 0.003 + 0.0003, \ldots$$

gets closer and closer to a limiting value of $\frac{1}{3}$ as more and more terms are included. Thus, limits even occur in the familiar context of decimal representations of real numbers.

## LIMITS

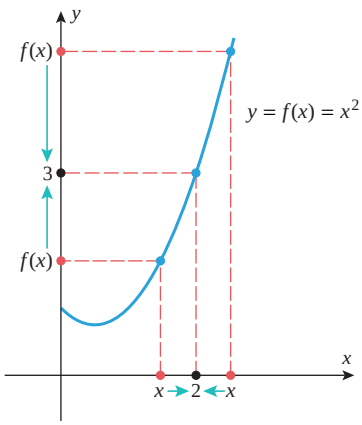
Now that we have seen how limits arise in various ways, let us focus on the limit concept itself.

The most basic use of limits is to describe how a function behaves as the independent variable approaches a given value. For example, let us examine the behavior of the function

$$f(x) = x^2 - x + 1$$

for $x$-values closer and closer to 2. It is evident from the graph and table in Figure 1.1.8 that the values of $f(x)$ get closer and closer to 3 as values of $x$ are selected closer and closer to 2 on either the left or the right side of 2. We describe this by saying that the "limit of $x^2 - x + 1$ is 3 as $x$ approaches 2 from either side," and we write

$$\lim_{x \to 2} (x^2 - x + 1) = 3 \tag{5}$$



| $x$ | 1.0 | 1.5 | 1.9 | 1.95 | 1.99 | 1.995 | 1.999 | 2 | 2.001 | 2.005 | 2.01 | 2.05 | 2.1 | 2.5 | 3.0 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| $f(x)$ | 1.000000 | 1.750000 | 2.710000 | 2.852500 | 2.970100 | 2.985025 | 2.997001 | | 3.003001 | 3.015025 | 3.030100 | 3.152500 | 3.310000 | 4.750000 | 7.000000 |

Left side → Right side

▲ **Figure 1.1.8**

This leads us to the following general idea.

**1.1.1 LIMITS (AN INFORMAL VIEW)** If the values of $f(x)$ can be made as close as we like to $L$ by taking values of $x$ sufficiently close to $a$ (but not equal to $a$), then we write

$$\lim_{x \to a} f(x) = L \tag{6}$$

which is read "the limit of $f(x)$ as $x$ approaches $a$ is $L$" or "$f(x)$ approaches $L$ as $x$ approaches $a$." The expression in (6) can also be written as

$$f(x) \to L \quad \text{as} \quad x \to a \tag{7}$$

Since $x$ is required to be different from $a$ in (6), the value of $f$ at $a$, or even whether $f$ is defined at $a$, has no bearing on the limit $L$. The limit describes the behavior of $f$ *close to* $a$ but not *at* $a$.

**Example 2** Use numerical evidence to make a conjecture about the value of

$$\lim_{x \to 1} \frac{x - 1}{\sqrt{x} - 1} \tag{8}$$

***Solution.*** Although the function

$$f(x) = \frac{x - 1}{\sqrt{x} - 1} \tag{9}$$

is undefined at $x = 1$, this has no bearing on the limit. Table 1.1.1 shows sample $x$-values approaching 1 from the left side and from the right side. In both cases the corresponding values of $f(x)$, calculated to six decimal places, appear to get closer and closer to 2, and hence we conjecture that

$$\lim_{x \to 1} \frac{x - 1}{\sqrt{x} - 1} = 2$$

This is consistent with the graph of $f$ shown in Figure 1.1.9. In the next section we will show how to obtain this result algebraically. ◀

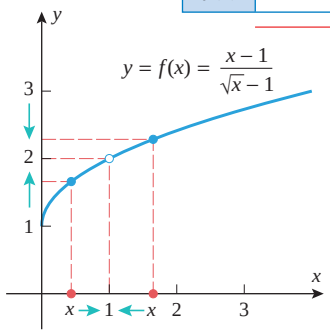
**TECHNOLOGY MASTERY**

Use a graphing utility to generate the graph of the equation $y = f(x)$ for the function in (9). Find a window containing $x = 1$ in which all values of $f(x)$ are within 0.5 of $y = 2$ and one in which all values of $f(x)$ are within 0.1 of $y = 2$.

**Table 1.1.1**

| $x$ | 0.99 | 0.999 | 0.9999 | 0.99999 | | 1.00001 | 1.0001 | 1.001 | 1.01 |
|---|---|---|---|---|---|---|---|---|---|
| $f(x)$ | 1.994987 | 1.999500 | 1.999950 | 1.999995 | | 2.000005 | 2.000050 | 2.000500 | 2.004988 |

Left side → ← Right side



▲ **Figure 1.1.9**

**Example 3** Use numerical evidence to make a conjecture about the value of

$$\lim_{x \to 0} \frac{\sin x}{x} \tag{10}$$

***Solution.*** With the help of a calculating utility set in radian mode, we obtain Table 1.1.2. The data in the table suggest that

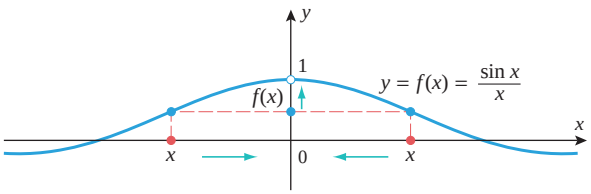
$$\lim_{x \to 0} \frac{\sin x}{x} = 1 \tag{11}$$

The result is consistent with the graph of $f(x) = (\sin x)/x$ shown in Figure 1.1.10. Later in this chapter we will give a geometric argument to prove that our conjecture is correct. ◀

Use numerical evidence to determine whether the limit in (11) changes if $x$ is measured in degrees.

**Table 1.1.2**

| $x$ (RADIANS) | $y = \dfrac{\sin x}{x}$ |
|---|---|
| ±1.0 | 0.84147 |
| ±0.9 | 0.87036 |
| ±0.8 | 0.89670 |
| ±0.7 | 0.92031 |
| ±0.6 | 0.94107 |
| ±0.5 | 0.95885 |
| ±0.4 | 0.97355 |
| ±0.3 | 0.98507 |
| ±0.2 | 0.99335 |
| ±0.1 | 0.99833 |
| ±0.01 | 0.99998 |



As $x$ approaches 0 from the left or right, $f(x)$ approaches 1.

▶ **Figure 1.1.10**

## SAMPLING PITFALLS

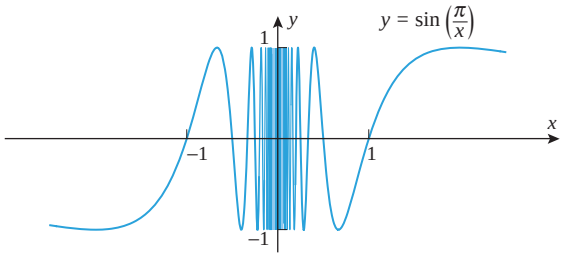
Numerical evidence can sometimes lead to incorrect conclusions about limits because of roundoff error or because the sample values chosen do not reveal the true limiting behavior. For example, one might *incorrectly* conclude from Table 1.1.3 that

$$\lim_{x \to 0} \sin\left(\frac{\pi}{x}\right) = 0$$

The fact that this is not correct is evidenced by the graph of $f$ in Figure 1.1.11. The graph reveals that the values of $f$ oscillate between $-1$ and 1 with increasing rapidity as $x \to 0$ and hence do not approach a limit. The data in the table deceived us because the $x$-values selected all happened to be $x$-intercepts for $f(x)$. This points out the need for having alternative methods for corroborating limits conjectured from numerical evidence.

**Table 1.1.3**

| $x$ | $\frac{\pi}{x}$ | $f(x) = \sin\left(\frac{\pi}{x}\right)$ |
|---|---|---|
| $x = \pm 1$ | $\pm\pi$ | $\sin(\pm\pi) = 0$ |
| $x = \pm 0.1$ | $\pm 10\pi$ | $\sin(\pm 10\pi) = 0$ |
| $x = \pm 0.01$ | $\pm 100\pi$ | $\sin(\pm 100\pi) = 0$ |
| $x = \pm 0.001$ | $\pm 1000\pi$ | $\sin(\pm 1000\pi) = 0$ |
| $x = \pm 0.0001$ | $\pm 10{,}000\pi$ | $\sin(\pm 10{,}000\pi) = 0$ |
| $\vdots$ | $\vdots$ | $\vdots$ |

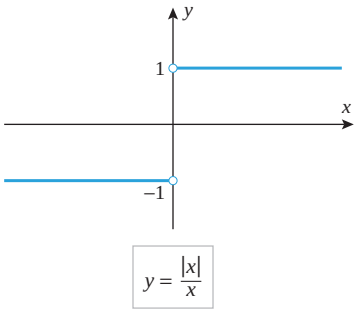


▲ **Figure 1.1.11**

## ONE-SIDED LIMITS

The limit in (6) is called a ***two-sided limit*** because it requires the values of $f(x)$ to get closer and closer to $L$ as values of $x$ are taken from *either* side of $x = a$. However, some functions exhibit different behaviors on the two sides of an $x$-value $a$, in which case it is necessary to distinguish whether values of $x$ near $a$ are on the left side or on the right side of $a$ for purposes of investigating limiting behavior. For example, consider the function

$$f(x) = \frac{|x|}{x} = \begin{cases} 1, & x > 0 \\ -1, & x < 0 \end{cases} \tag{12}$$



▲ **Figure 1.1.12**

which is graphed in Figure 1.1.12. As $x$ approaches 0 from the *right*, the values of $f(x)$ approach a limit of 1 [in fact, the values of $f(x)$ are exactly 1 for all such $x$], and similarly, as $x$ approaches 0 from the *left*, the values of $f(x)$ approach a limit of $-1$. We denote these limits by writing

$$\lim_{x \to 0^+} \frac{|x|}{x} = 1 \quad \text{and} \quad \lim_{x \to 0^-} \frac{|x|}{x} = -1 \tag{13}$$

With this notation, the superscript "+" indicates a limit from the right and the superscript "−" indicates a limit from the left.

This leads to the general idea of a ***one-sided limit***.

As with two-sided limits, the one-sided limits in (14) and (15) can also be written as

$$f(x) \to L \quad \text{as} \quad x \to a^+$$

and

$$f(x) \to L \quad \text{as} \quad x \to a^-$$

respectively.

**1.1.2 ONE-SIDED LIMITS (AN INFORMAL VIEW)** If the values of $f(x)$ can be made as close as we like to $L$ by taking values of $x$ sufficiently close to $a$ (but greater than $a$), then we write

$$\lim_{x \to a^+} f(x) = L \tag{14}$$

and if the values of $f(x)$ can be made as close as we like to $L$ by taking values of $x$ sufficiently close to $a$ (but less than $a$), then we write

$$\lim_{x \to a^-} f(x) = L \tag{15}$$

Expression (14) is read "the limit of $f(x)$ as $x$ approaches $a$ from the right is $L$" or "$f(x)$ approaches $L$ as $x$ approaches $a$ from the right." Similarly, expression (15) is read "the limit of $f(x)$ as $x$ approaches $a$ from the left is $L$" or "$f(x)$ approaches $L$ as $x$ approaches $a$ from the left."

## THE RELATIONSHIP BETWEEN ONE-SIDED LIMITS AND TWO-SIDED LIMITS

In general, there is no guarantee that a function $f$ will have a two-sided limit at a given point $a$; that is, the values of $f(x)$ may not get closer and closer to any *single* real number $L$ as $x \to a$. In this case we say that

$$\lim_{x \to a} f(x) \quad \textbf{\textit{does not exist}}$$

Similarly, the values of $f(x)$ may not get closer and closer to a single real number $L$ as $x \to a^+$ or as $x \to a^-$. In these cases we say that

$$\lim_{x \to a^+} f(x) \quad \textbf{\textit{does not exist}}$$

or that

$$\lim_{x \to a^-} f(x) \quad \textbf{\textit{does not exist}}$$

In order for the two-sided limit of a function $f(x)$ to exist at a point $a$, the values of $f(x)$ must approach some real number $L$ as $x$ approaches $a$, and this number must be the same regardless of whether $x$ approaches $a$ from the left or the right. This suggests the following result, which we state without formal proof.

**1.1.3 THE RELATIONSHIP BETWEEN ONE-SIDED AND TWO-SIDED LIMITS** The two-sided limit of a function $f(x)$ exists at $a$ if and only if both of the one-sided limits exist at $a$ and have the same value; that is,

$$\lim_{x \to a} f(x) = L \quad \text{if and only if} \quad \lim_{x \to a^-} f(x) = L = \lim_{x \to a^+} f(x)$$

**▶ Example 4** Explain why

$$\lim_{x \to 0} \frac{|x|}{x}$$

does not exist.

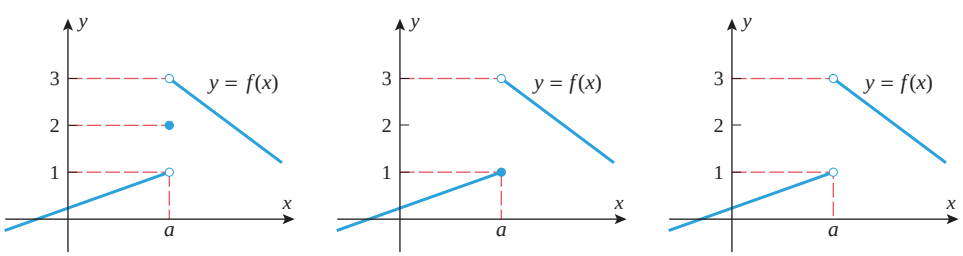
***Solution.*** As $x$ approaches 0, the values of $f(x) = |x|/x$ approach $-1$ from the left and approach 1 from the right [see (13)]. Thus, the one-sided limits at 0 are not the same. ◀

**▶ Example 5** For the functions in Figure 1.1.13, find the one-sided and two-sided limits at $x = a$ if they exist.

***Solution.*** The functions in all three figures have the same one-sided limits as $x \to a$, since the functions are identical, except at $x = a$. These limits are

$$\lim_{x \to a^+} f(x) = 3 \quad \text{and} \quad \lim_{x \to a^-} f(x) = 1$$

In all three cases the two-sided limit does not exist as $x \to a$ because the one-sided limits are not equal. ◀



▶ Figure 1.1.13

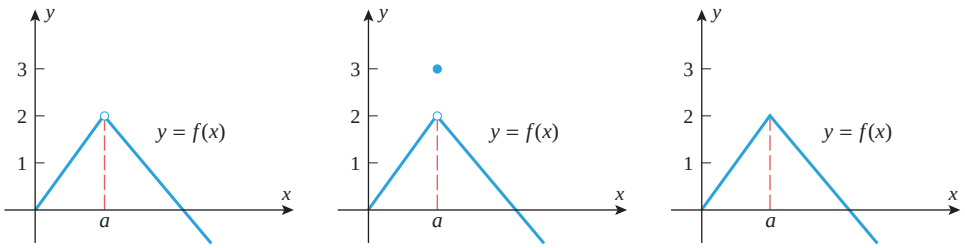
► **Example 6** For the functions in Figure 1.1.14, find the one-sided and two-sided limits at $x = a$ if they exist.

***Solution.*** As in the preceding example, the value of $f$ at $x = a$ has no bearing on the limits as $x \to a$, so in all three cases we have

$$\lim_{x \to a^+} f(x) = 2 \quad \text{and} \quad \lim_{x \to a^-} f(x) = 2$$

Since the one-sided limits are equal, the two-sided limit exists and

$$\lim_{x \to a} f(x) = 2 \ \blacktriangleleft$$



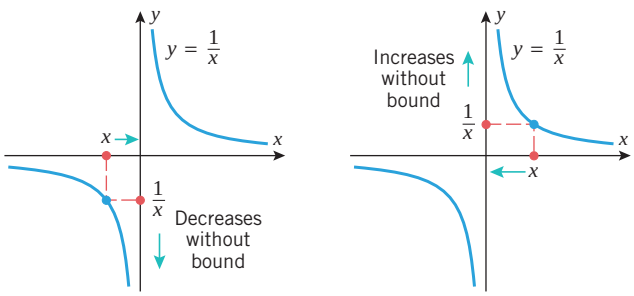
▲ **Figure 1.1.14**

## INFINITE LIMITS

Sometimes one-sided or two-sided limits fail to exist because the values of the function increase or decrease without bound. For example, consider the behavior of $f(x) = 1/x$ for values of $x$ near 0. It is evident from the table and graph in Figure 1.1.15 that as $x$-values are taken closer and closer to 0 from the right, the values of $f(x) = 1/x$ are positive and increase without bound; and as $x$-values are taken closer and closer to 0 from the left, the values of $f(x) = 1/x$ are negative and decrease without bound. We describe these limiting behaviors by writing

$$\lim_{x \to 0^+} \frac{1}{x} = +\infty \quad \text{and} \quad \lim_{x \to 0^-} \frac{1}{x} = -\infty$$

The symbols $+\infty$ and $-\infty$ here are *not* real numbers; they simply describe particular ways in which the limits fail to exist. Do not make the mistake of manipulating these symbols using rules of algebra. For example, it is *incorrect* to write $(+\infty) - (+\infty) = 0$.



| $x$ | −1 | −0.1 | −0.01 | −0.001 | −0.0001 | 0 | 0.0001 | 0.001 | 0.01 | 0.1 | 1 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| $\frac{1}{x}$ | −1 | −10 | −100 | −1000 | −10,000 | | 10,000 | 1000 | 100 | 10 | 1 |

Left side → ← Right side

▲ **Figure 1.1.15**

**1.1.4 INFINITE LIMITS (AN INFORMAL VIEW)** The expressions

$$\lim_{x \to a^-} f(x) = +\infty \quad \text{and} \quad \lim_{x \to a^+} f(x) = +\infty$$

denote that $f(x)$ increases without bound as $x$ approaches $a$ from the left and from the right, respectively. If both are true, then we write

$$\lim_{x \to a} f(x) = +\infty$$

Similarly, the expressions

$$\lim_{x \to a^-} f(x) = -\infty \quad \text{and} \quad \lim_{x \to a^+} f(x) = -\infty$$

denote that $f(x)$ decreases without bound as $x$ approaches $a$ from the left and from the right, respectively. If both are true, then we write

$$\lim_{x \to a} f(x) = -\infty$$

▶ **Example 7** For the functions in Figure 1.1.16, describe the limits at $x = a$ in appropriate limit notation.

***Solution (a).*** In Figure 1.1.16*a*, the function increases without bound as $x$ approaches $a$ from the right and decreases without bound as $x$ approaches $a$ from the left. Thus,

$$\lim_{x \to a^+} \frac{1}{x - a} = +\infty \quad \text{and} \quad \lim_{x \to a^-} \frac{1}{x - a} = -\infty$$

***Solution (b).*** In Figure 1.1.16*b*, the function increases without bound as $x$ approaches $a$ from both the left and right. Thus,

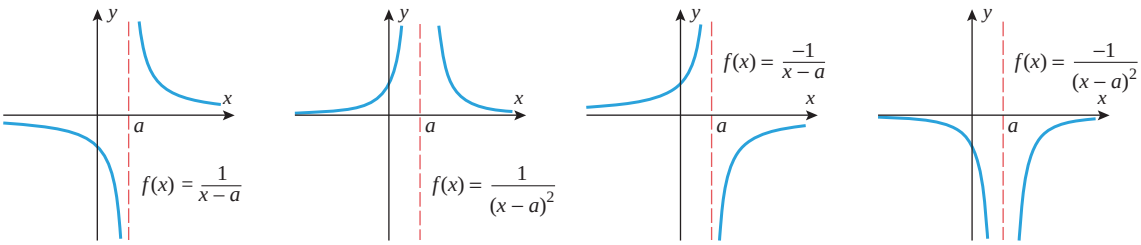
$$\lim_{x \to a} \frac{1}{(x - a)^2} = \lim_{x \to a^+} \frac{1}{(x - a)^2} = \lim_{x \to a^-} \frac{1}{(x - a)^2} = +\infty$$

***Solution (c).*** In Figure 1.1.16*c*, the function decreases without bound as $x$ approaches $a$ from the right and increases without bound as $x$ approaches $a$ from the left. Thus,

$$\lim_{x \to a^+} \frac{-1}{x - a} = -\infty \quad \text{and} \quad \lim_{x \to a^-} \frac{-1}{x - a} = +\infty$$

***Solution (d).*** In Figure 1.1.16*d*, the function decreases without bound as $x$ approaches $a$ from both the left and right. Thus,

$$\lim_{x \to a} \frac{-1}{(x - a)^2} = \lim_{x \to a^+} \frac{-1}{(x - a)^2} = \lim_{x \to a^-} \frac{-1}{(x - a)^2} = -\infty \quad \blacktriangleleft$$



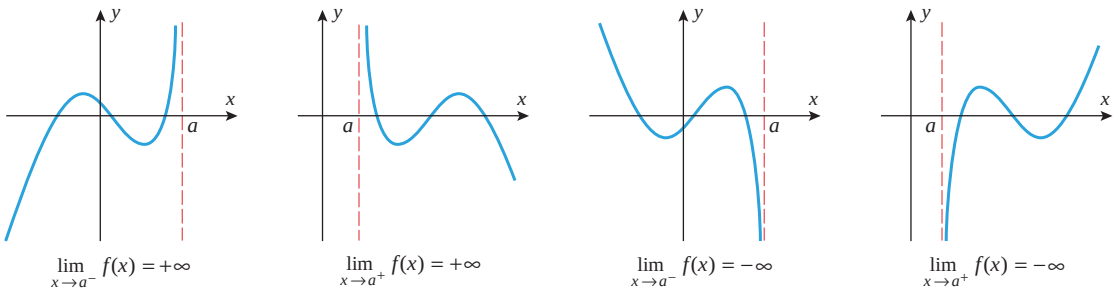
▲ **Figure 1.1.16**

## VERTICAL ASYMPTOTES

Figure 1.1.17 illustrates geometrically what happens when any of the following situations occur:

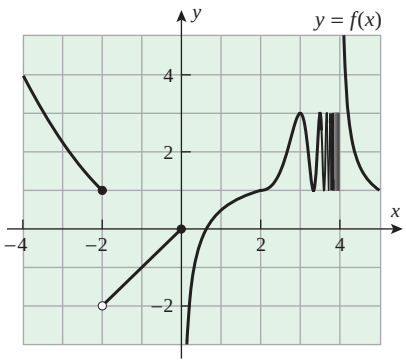
$$\lim_{x\to a^-} f(x) = +\infty, \quad \lim_{x\to a^+} f(x) = +\infty, \quad \lim_{x\to a^-} f(x) = -\infty, \quad \lim_{x\to a^+} f(x) = -\infty$$

In each case the graph of $y = f(x)$ either rises or falls without bound, squeezing closer and closer to the vertical line $x = a$ as $x$ approaches $a$ from the side indicated in the limit. The line $x = a$ is called a ***vertical asymptote*** of the curve $y = f(x)$ (from the Greek word *asymptotos*, meaning "nonintersecting").



▲ **Figure 1.1.17**

In general, the graph of a single function can display a wide variety of limits.



▲ **Figure 1.1.18**

► **Example 8** For the function $f$ graphed in Figure 1.1.18, find

(a) $\lim_{x\to -2^-} f(x)$ (b) $\lim_{x\to -2^+} f(x)$ (c) $\lim_{x\to 0^-} f(x)$ (d) $\lim_{x\to 0^+} f(x)$
(e) $\lim_{x\to 4^-} f(x)$ (f) $\lim_{x\to 4^+} f(x)$ (g) the vertical asymptotes of the graph of $f$.

***Solution (a) and (b).***

$$\lim_{x\to -2^-} f(x) = 1 = f(-2) \quad \text{and} \quad \lim_{x\to -2^+} f(x) = -2$$

***Solution (c) and (d).***

$$\lim_{x\to 0^-} f(x) = 0 = f(0) \quad \text{and} \quad \lim_{x\to 0+} f(x) = -\infty$$

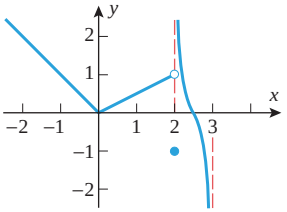
***Solution (e) and (f).***

$$\lim_{x\to 4^-} f(x) \text{ does not exist due to oscillation} \quad \text{and} \quad \lim_{x\to 4^+} f(x) = +\infty$$

***Solution (g).*** The $y$-axis and the line $x = 4$ are vertical asymptotes for the graph of $f$. ◄

## ✔ QUICK CHECK EXERCISES 1.1 (See page 79 for answers.)

1. We write $\lim_{x\to a} f(x) = L$ provided the values of _____ can be made as close to _____ as desired, by taking values of _____ sufficiently close to _____ but not _____.
2. We write $\lim_{x\to a^-} f(x) = +\infty$ provided _____ increases without bound, as _____ approaches _____ from the left.
3. State what must be true about
$$\lim_{x\to a^-} f(x) \quad \text{and} \quad \lim_{x\to a^+} f(x)$$
in order for it to be the case that
$$\lim_{x\to a} f(x) = L$$
4. Use the accompanying graph of $y = f(x)$ $(-\infty < x < 3)$ to determine the limits.
(a) $\lim_{x\to 0} f(x) =$ _____
(b) $\lim_{x\to 2^-} f(x) =$ _____
(c) $\lim_{x\to 2^+} f(x) =$ _____
(d) $\lim_{x\to 3^-} f(x) =$ _____



◄ **Figure Ex-4**

5. The slope of the secant line through $P(2, 4)$ and $Q(x, x^2)$ on the parabola $y = x^2$ is $m_{\text{sec}} = x + 2$. It follows that the slope of the tangent line to this parabola at the point $P$ is _____.

**17.** If $f(a) = L$, then $\lim_{x\to a} f(x) = L$.

**18.** If $\lim_{x\to a} f(x)$ exists, then so do $\lim_{x\to a^-} f(x)$ and $\lim_{x\to a^+} f(x)$.

**19.** If $\lim_{x\to a^-} f(x)$ and $\lim_{x\to a^+} f(x)$ exist, then so does $\lim_{x\to a} f(x)$.

**20.** If $\lim_{x\to a^+} f(x) = +\infty$, then $f(a)$ is undefined.

**21–26** Sketch a possible graph for a function $f$ with the specified properties. (Many different solutions are possible.) ■

**21.** (i) the domain of $f$ is $[-1, 1]$
(ii) $f(-1) = f(0) = f(1) = 0$
(iii) $\lim_{x\to -1^+} f(x) = \lim_{x\to 0} f(x) = \lim_{x\to 1^-} f(x) = 1$

**22.** (i) the domain of $f$ is $[-2, 1]$
(ii) $f(-2) = f(0) = f(1) = 0$
(iii) $\lim_{x\to -2^+} f(x) = 2$, $\lim_{x\to 0} f(x) = 0$, and $\lim_{x\to 1^-} f(x) = 1$

**23.** (i) the domain of $f$ is $(-\infty, 0]$
(ii) $f(-2) = f(0) = 1$
(iii) $\lim_{x\to -2} f(x) = +\infty$

**24.** (i) the domain of $f$ is $(0, +\infty)$
(ii) $f(1) = 0$
(iii) the $y$-axis is a vertical asymptote for the graph of $f$
(iv) $f(x) < 0$ if $0 < x < 1$

**25.** (i) $f(-3) = f(0) = f(2) = 0$

(ii) $\lim_{x \to -2^-} f(x) = +\infty$ and $\lim_{x \to -2^+} f(x) = -\infty$

(iii) $\lim_{x \to 1} f(x) = +\infty$

**26.** (i) $f(-1) = 0$, $f(0) = 1$, $f(1) = 0$

(ii) $\lim_{x \to -1^-} f(x) = 0$ and $\lim_{x \to -1^+} f(x) = +\infty$

(iii) $\lim_{x \to 1^-} f(x) = 1$ and $\lim_{x \to 1^+} f(x) = +\infty$

**27–30** Modify the argument of Example 1 to find the equation of the tangent line to the specified graph at the point given. ■

**27.** the graph of $y = x^2$ at $(-1, 1)$

**28.** the graph of $y = x^2$ at $(0, 0)$

**29.** the graph of $y = x^4$ at $(1, 1)$

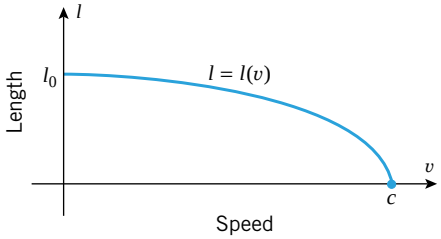
**30.** the graph of $y = x^4$ at $(-1, 1)$

## FOCUS ON CONCEPTS

**31.** In the special theory of relativity the length $l$ of a narrow rod moving longitudinally is a function $l = l(v)$ of the rod's speed $v$. The accompanying figure, in which $c$ denotes the speed of light, displays some of the qualitative features of this function.

(a) What is the physical interpretation of $l_0$?

(b) What is $\lim_{v \to c^-} l(v)$? What is the physical significance of this limit?

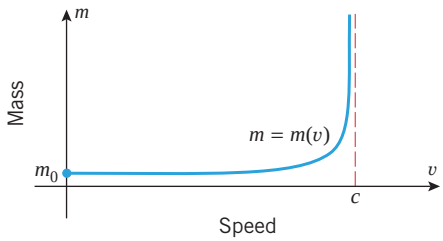


▲ **Figure Ex-31**

**32.** In the special theory of relativity the mass $m$ of a moving object is a function $m = m(v)$ of the object's speed $v$. The accompanying figure, in which $c$ denotes the speed of light, displays some of the qualitative features of this function.

(a) What is the physical interpretation of $m_0$?

(b) What is $\lim_{v \to c^-} m(v)$? What is the physical significance of this limit?



▲ **Figure Ex-32**

**33.** Let

$$f(x) = \left(1 + x^2\right)^{1.1/x^2}$$

(a) Graph $f$ in the window

$$[-1, 1] \times [2.5, 3.5]$$

and use the calculator's trace feature to make a conjecture about the limit of $f(x)$ as $x \to 0$.

(b) Graph $f$ in the window

$$[-0.001, 0.001] \times [2.5, 3.5]$$

and use the calculator's trace feature to make a conjecture about the limit of $f(x)$ as $x \to 0$.

(c) Graph $f$ in the window

$$[-0.000001, 0.000001] \times [2.5, 3.5]$$

and use the calculator's trace feature to make a conjecture about the limit of $f(x)$ as $x \to 0$.

(d) Later we will be able to show that

$$\lim_{x \to 0} \left(1 + x^2\right)^{1.1/x^2} \approx 3.00416602$$

What flaw do your graphs reveal about using numerical evidence (as revealed by the graphs you obtained) to make conjectures about limits?

**34. Writing** Two students are discussing the limit of $\sqrt{x}$ as $x$ approaches 0. One student maintains that the limit is 0, while the other claims that the limit does not exist. Write a short paragraph that discusses the pros and cons of each student's position.

**35. Writing** Given a function $f$ and a real number $a$, explain informally why

$$\lim_{x \to 0} f(x + a) = \lim_{x \to a} f(x)$$

(Here "equality" means that either both limits exist and are equal or that both limits fail to exist.)

## ✔ QUICK CHECK ANSWERS 1.1

# 1.2 COMPUTING LIMITS

*In this section we will discuss techniques for computing limits of many functions. We base these results on the informal development of the limit concept discussed in the preceding section. A more formal derivation of these results is possible after Section 1.4.*

## SOME BASIC LIMITS

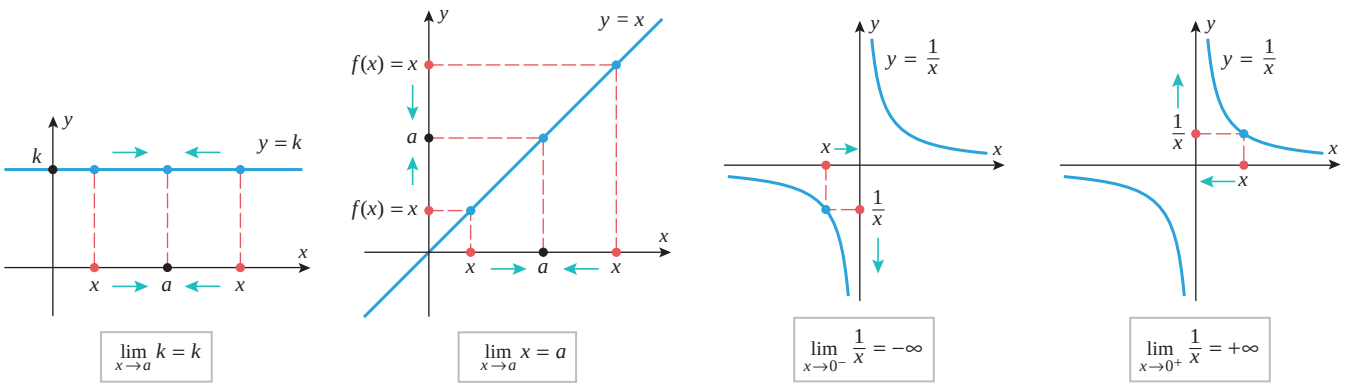
Our strategy for finding limits algebraically has two parts:

- First we will obtain the limits of some simple functions.
- Then we will develop a repertoire of theorems that will enable us to use the limits of those simple functions as building blocks for finding limits of more complicated functions.

We start with the following basic results, which are illustrated in Figure 1.2.1.

**1.2.1 THEOREM** *Let $a$ and $k$ be real numbers.*

(a) $\lim_{x \to a} k = k$ (b) $\lim_{x \to a} x = a$ (c) $\lim_{x \to 0^-} \frac{1}{x} = -\infty$ (d) $\lim_{x \to 0^+} \frac{1}{x} = +\infty$



▲ **Figure 1.2.1**

The following examples explain these results further.

**▶ Example 1** If $f(x) = k$ is a constant function, then the values of $f(x)$ remain fixed at $k$ as $x$ varies, which explains why $f(x) \to k$ as $x \to a$ for all values of $a$. For example,

$$\lim_{x \to -25} 3 = 3, \qquad \lim_{x \to 0} 3 = 3, \qquad \lim_{x \to \pi} 3 = 3 \quad \blacktriangleleft$$

**▶ Example 2** If $f(x) = x$, then as $x \to a$ it must also be true that $f(x) \to a$. For example,

$$\lim_{x \to 0} x = 0, \qquad \lim_{x \to -2} x = -2, \qquad \lim_{x \to \pi} x = \pi \quad \blacktriangleleft$$

Do not confuse the algebraic size of a number with its closeness to zero. For positive numbers, the smaller the number the closer it is to zero, but for negative numbers, the larger the number the closer it is to zero. For example, $-2$ is larger than $-4$, but it is closer to zero.

▶ **Example 3** You should know from your experience with fractions that for a fixed nonzero numerator, the closer the denominator is to zero, the larger the absolute value of the fraction. This fact and the data in Table 1.2.1 suggest why $1/x \to +\infty$ as $x \to 0^+$ and why $1/x \to -\infty$ as $x \to 0^-$. ◀

**Table 1.2.1**

| | VALUES | | | | | | CONCLUSION |
|---|---|---|---|---|---|---|---|
| $x$ | $-1$ | $-0.1$ | $-0.01$ | $-0.001$ | $-0.0001$ | $\cdots$ | As $x \to 0^-$ the value of $1/x$ decreases without bound. |
| $1/x$ | $-1$ | $-10$ | $-100$ | $-1000$ | $-10{,}000$ | $\cdots$ | |
| $x$ | $1$ | $0.1$ | $0.01$ | $0.001$ | $0.0001$ | $\cdots$ | As $x \to 0^+$ the value of $1/x$ increases without bound. |
| $1/x$ | $1$ | $10$ | $100$ | $1000$ | $10{,}000$ | $\cdots$ | |

The following theorem, parts of which are proved in Appendix D, will be our basic tool for finding limits algebraically.

**1.2.2 THEOREM** *Let $a$ be a real number, and suppose that*

$$\lim_{x \to a} f(x) = L_1 \quad \text{and} \quad \lim_{x \to a} g(x) = L_2$$

*That is, the limits exist and have values $L_1$ and $L_2$, respectively. Then:*

(a) $\lim_{x \to a} [f(x) + g(x)] = \lim_{x \to a} f(x) + \lim_{x \to a} g(x) = L_1 + L_2$

(b) $\lim_{x \to a} [f(x) - g(x)] = \lim_{x \to a} f(x) - \lim_{x \to a} g(x) = L_1 - L_2$

(c) $\lim_{x \to a} [f(x)g(x)] = \left(\lim_{x \to a} f(x)\right)\left(\lim_{x \to a} g(x)\right) = L_1 L_2$

(d) $\lim_{x \to a} \dfrac{f(x)}{g(x)} = \dfrac{\lim_{x \to a} f(x)}{\lim_{x \to a} g(x)} = \dfrac{L_1}{L_2}$, *provided* $L_2 \neq 0$

(e) $\lim_{x \to a} \sqrt[n]{f(x)} = \sqrt[n]{\lim_{x \to a} f(x)} = \sqrt[n]{L_1}$, *provided* $L_1 > 0$ *if $n$ is even.*

*Moreover, these statements are also true for the one-sided limits as $x \to a^-$ or as $x \to a^+$.*

Theorem 1.2.2(e) remains valid for $n$ even and $L_1 = 0$, provided $f(x)$ is nonnegative for $x$ near $a$ with $x \neq a$.

This theorem can be stated informally as follows:

(a) *The limit of a sum is the sum of the limits.*
(b) *The limit of a difference is the difference of the limits.*
(c) *The limit of a product is the product of the limits.*
(d) *The limit of a quotient is the quotient of the limits, provided the limit of the denominator is not zero.*
(e) *The limit of an nth root is the nth root of the limit.*

For the special case of part (c) in which $f(x) = k$ is a constant function, we have

$$\lim_{x \to a} (kg(x)) = \lim_{x \to a} k \cdot \lim_{x \to a} g(x) = k \lim_{x \to a} g(x) \tag{1}$$

and similarly for one-sided limits. This result can be rephrased as follows:

*A constant factor can be moved through a limit symbol.*

Although parts $(a)$ and $(c)$ of Theorem 1.2.2 are stated for two functions, the results hold for any finite number of functions. Moreover, the various parts of the theorem can be used in combination to reformulate expressions involving limits.

**▶ Example 4**

$$\lim_{x\to a}[f(x)-g(x)+2h(x)]=\lim_{x\to a}f(x)-\lim_{x\to a}g(x)+2\lim_{x\to a}h(x)$$

$$\lim_{x\to a}[f(x)g(x)h(x)]=\left(\lim_{x\to a}f(x)\right)\left(\lim_{x\to a}g(x)\right)\left(\lim_{x\to a}h(x)\right)$$

$$\lim_{x\to a}[f(x)]^3=\left(\lim_{x\to a}f(x)\right)^3$$

Take $g(x)=h(x)=f(x)$ in the last equation.

$$\lim_{x\to a}[f(x)]^n=\left(\lim_{x\to a}f(x)\right)^n$$

The extension of Theorem 1.2.2$(c)$ in which there are $n$ factors, each of which is $f(x)$

$$\lim_{x\to a}x^n=\left(\lim_{x\to a}x\right)^n=a^n$$

Apply the previous result with $f(x)=x$. ◀

## LIMITS OF POLYNOMIALS AND RATIONAL FUNCTIONS AS $x\to a$

**▶ Example 5** Find $\lim_{x\to 5}(x^2-4x+3)$.

***Solution.***

$$\lim_{x\to 5}(x^2-4x+3)=\lim_{x\to 5}x^2-\lim_{x\to 5}4x+\lim_{x\to 5}3$$

Theorem 1.2.2$(a)$, $(b)$

$$=\lim_{x\to 5}x^2-4\lim_{x\to 5}x+\lim_{x\to 5}3$$

A constant can be moved through a limit symbol.

$$=5^2-4(5)+3$$

The last part of Example 4

$$=8$$ ◀

Observe that in Example 5 the limit of the polynomial $p(x)=x^2-4x+3$ as $x\to 5$ turned out to be the same as $p(5)$. This is not an accident. The next result shows that, in general, the limit of a polynomial $p(x)$ as $x\to a$ is the same as the value of the polynomial at $a$. Knowing this fact allows us to reduce the computation of limits of polynomials to simply evaluating the polynomial at the appropriate point.

**1.2.3 THEOREM** *For any polynomial*

$$p(x)=c_0+c_1x+\cdots+c_nx^n$$

*and any real number $a$,*

$$\lim_{x\to a}p(x)=c_0+c_1a+\cdots+c_na^n=p(a)$$

**PROOF**

$$\begin{aligned}\lim_{x\to a} p(x) &= \lim_{x\to a}\left(c_0 + c_1x + \cdots + c_nx^n\right)\\ &= \lim_{x\to a} c_0 + \lim_{x\to a} c_1x + \cdots + \lim_{x\to a} c_nx^n\\ &= \lim_{x\to a} c_0 + c_1\lim_{x\to a} x + \cdots + c_n\lim_{x\to a} x^n\\ &= c_0 + c_1a + \cdots + c_na^n = p(a)\end{aligned}$$ ■

**▶ Example 6** Find $\lim_{x\to 1}(x^7 - 2x^5 + 1)^{35}$.

***Solution.*** The function involved is a polynomial (why?), so the limit can be obtained by evaluating this polynomial at $x = 1$. This yields

$$\lim_{x\to 1}(x^7 - 2x^5 + 1)^{35} = 0$$ ◀

Recall that a rational function is a ratio of two polynomials. The following example illustrates how Theorems 1.2.2($d$) and 1.2.3 can sometimes be used in combination to compute limits of rational functions.

**▶ Example 7** Find $\lim_{x\to 2}\dfrac{5x^3 + 4}{x - 3}$.

***Solution.***

$$\lim_{x\to 2}\frac{5x^3 + 4}{x - 3} = \frac{\lim_{x\to 2}(5x^3 + 4)}{\lim_{x\to 2}(x - 3)}$$ Theorem 1.2.2($d$)

$$= \frac{5\cdot 2^3 + 4}{2 - 3} = -44$$ Theorem 1.2.3 ◀

The method used in the last example will not work for rational functions in which the limit of the denominator is zero because Theorem 1.2.2($d$) is not applicable. There are two cases of this type to be considered—the case where the limit of the denominator is zero and the limit of the numerator is not, and the case where the limits of the numerator and denominator are both zero. If the limit of the denominator is zero but the limit of the numerator is not, then one can prove that the limit of the rational function does not exist and that one of the following situations occurs:

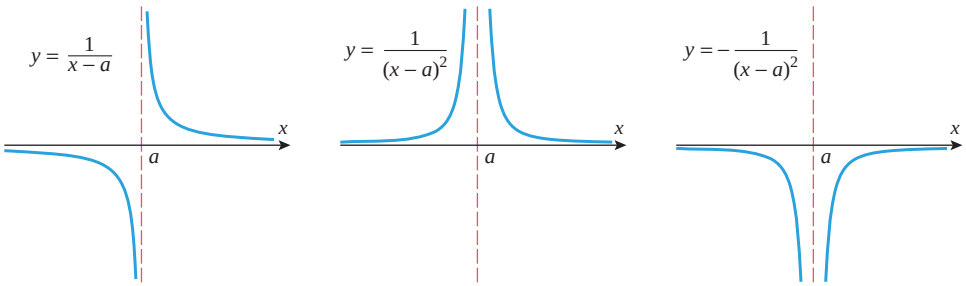
- The limit may be $-\infty$ from one side and $+\infty$ from the other.
- The limit may be $+\infty$.
- The limit may be $-\infty$.

Figure 1.2.2 illustrates these three possibilities graphically for rational functions of the form $1/(x - a)$, $1/(x - a)^2$, and $-1/(x - a)^2$.

**▶ Example 8** Find

(a) $\lim_{x\to 4^+}\dfrac{2 - x}{(x - 4)(x + 2)}$ (b) $\lim_{x\to 4^-}\dfrac{2 - x}{(x - 4)(x + 2)}$ (c) $\lim_{x\to 4}\dfrac{2 - x}{(x - 4)(x + 2)}$

***Solution.*** In all three parts the limit of the numerator is $-2$, and the limit of the denominator is 0, so the limit of the ratio does not exist. To be more specific than this, we need

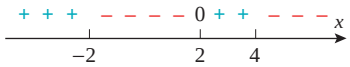


$\lim_{x\to a^+} \frac{1}{x-a} = +\infty$
$\lim_{x\to a^-} \frac{1}{x-a} = -\infty$

$\lim_{x\to a} \frac{1}{(x-a)^2} = +\infty$

$\lim_{x\to a} -\frac{1}{(x-a)^2} = -\infty$

▲ **Figure 1.2.2**



Sign of $\frac{2-x}{(x-4)(x+2)}$

▲ **Figure 1.2.3**

to analyze the sign of the ratio. The sign of the ratio, which is given in Figure 1.2.3, is determined by the signs of $2-x$, $x-4$, and $x+2$. (The method of test points, discussed in Web Appendix E, provides a way of finding the sign of the ratio here.) It follows from this figure that as $x$ approaches 4 from the right, the ratio is always negative; and as $x$ approaches 4 from the left, the ratio is eventually positive. Thus,

$$\lim_{x\to 4^+} \frac{2-x}{(x-4)(x+2)} = -\infty \quad \text{and} \quad \lim_{x\to 4^-} \frac{2-x}{(x-4)(x+2)} = +\infty$$

Because the one-sided limits have opposite signs, all we can say about the two-sided limit is that it does not exist. ◄

In the case where $p(x)/q(x)$ is a rational function for which $p(a) = 0$ and $q(a) = 0$, the numerator and denominator must have one or more common factors of $x-a$. In this case the limit of $p(x)/q(x)$ as $x \to a$ can be found by canceling all common factors of $x-a$ and using one of the methods already considered to find the limit of the simplified function. Here is an example.

In Example 9(a), the simplified function $x-3$ is defined at $x=3$, but the original function is not. However, this has no effect on the limit as $x$ *approaches* 3 since the two functions are identical if $x \neq 3$ (Exercise 50).

► **Example 9** Find

(a) $\lim_{x\to 3} \frac{x^2-6x+9}{x-3}$ (b) $\lim_{x\to -4} \frac{2x+8}{x^2+x-12}$ (c) $\lim_{x\to 5} \frac{x^2-3x-10}{x^2-10x+25}$

***Solution (a).*** The numerator and the denominator both have a zero at $x=3$, so there is a common factor of $x-3$. Then

$$\lim_{x\to 3} \frac{x^2-6x+9}{x-3} = \lim_{x\to 3} \frac{(x-3)^2}{x-3} = \lim_{x\to 3} (x-3) = 0$$

***Solution (b).*** The numerator and the denominator both have a zero at $x=-4$, so there is a common factor of $x-(-4) = x+4$. Then

$$\lim_{x\to -4} \frac{2x+8}{x^2+x-12} = \lim_{x\to -4} \frac{2(x+4)}{(x+4)(x-3)} = \lim_{x\to -4} \frac{2}{x-3} = -\frac{2}{7}$$

***Solution (c).*** The numerator and the denominator both have a zero at $x=5$, so there is a common factor of $x-5$. Then

$$\lim_{x\to 5} \frac{x^2-3x-10}{x^2-10x+25} = \lim_{x\to 5} \frac{(x-5)(x+2)}{(x-5)(x-5)} = \lim_{x\to 5} \frac{x+2}{x-5}$$

However,

$$\lim_{x\to 5}(x+2) = 7 \neq 0 \quad \text{and} \quad \lim_{x\to 5}(x-5) = 0$$

so

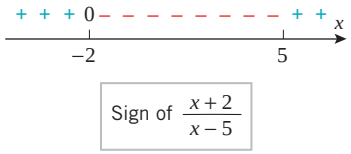
$$\lim_{x\to 5}\frac{x^2-3x-10}{x^2-10x+25} = \lim_{x\to 5}\frac{x+2}{x-5}$$

does not exist. More precisely, the sign analysis in Figure 1.2.4 implies that

$$\lim_{x\to 5^+}\frac{x^2-3x-10}{x^2-10x+25} = \lim_{x\to 5^+}\frac{x+2}{x-5} = +\infty$$

and

$$\lim_{x\to 5^-}\frac{x^2-3x-10}{x^2-10x+25} = \lim_{x\to 5^-}\frac{x+2}{x-5} = -\infty \quad \blacktriangleleft$$



▲ **Figure 1.2.4**

Discuss the logical errors in the following statement: An indeterminate form of type $0/0$ must have a limit of zero because zero divided by anything is zero.

A quotient $f(x)/g(x)$ in which the numerator and denominator both have a limit of zero as $x \to a$ is called an ***indeterminate form of type*** $\mathbf{0/0}$. The problem with such limits is that it is difficult to tell by inspection whether the limit exists, and, if so, its value. Informally stated, this is because there are two conflicting influences at work. The value of $f(x)/g(x)$ would tend to zero as $f(x)$ approached zero if $g(x)$ were to remain at some fixed nonzero value, whereas the value of this ratio would tend to increase or decrease without bound as $g(x)$ approached zero if $f(x)$ were to remain at some fixed nonzero value. But with both $f(x)$ and $g(x)$ approaching zero, the behavior of the ratio depends on precisely how these conflicting tendencies offset one another for the particular $f$ and $g$.

Sometimes, limits of indeterminate forms of type $0/0$ can be found by algebraic simplification, as in the last example, but frequently this will not work and other methods must be used. We will study such methods in later sections.

The following theorem summarizes our observations about limits of rational functions.

**1.2.4 THEOREM** *Let*

$$f(x) = \frac{p(x)}{q(x)}$$

*be a rational function, and let $a$ be any real number.*

(a) *If $q(a) \neq 0$, then $\lim_{x\to a} f(x) = f(a)$.*

(b) *If $q(a) = 0$ but $p(a) \neq 0$, then $\lim_{x\to a} f(x)$ does not exist.*

## LIMITS INVOLVING RADICALS

▶ **Example 10** Find $\lim_{x\to 1}\dfrac{x-1}{\sqrt{x}-1}$.

***Solution.*** In Example 2 of Section 1.1 we used numerical evidence to conjecture that this limit is 2. Here we will confirm this algebraically. Since this limit is an indeterminate form of type $0/0$, we will need to devise some strategy for making the limit (if it exists) evident. One such strategy is to rationalize the denominator of the function. This yields

$$\frac{x-1}{\sqrt{x}-1} = \frac{(x-1)(\sqrt{x}+1)}{(\sqrt{x}-1)(\sqrt{x}+1)} = \frac{(x-1)(\sqrt{x}+1)}{x-1} = \sqrt{x}+1 \quad (x \neq 1)$$

Confirm the limit in Example 10 by factoring the numerator.

Therefore,

$$\lim_{x\to 1}\frac{x-1}{\sqrt{x}-1}=\lim_{x\to 1}(\sqrt{x}+1)=2 \quad \blacktriangleleft$$

## LIMITS OF PIECEWISE-DEFINED FUNCTIONS

For functions that are defined piecewise, a two-sided limit at a point where the formula changes is best obtained by first finding the one-sided limits at that point.

**▶ Example 11** Let

$$f(x)=\begin{cases}1/(x+2), & x<-2\\ x^2-5, & -2<x\le 3\\ \sqrt{x+13}, & x>3\end{cases}$$

Find

$$\text{(a)}\ \lim_{x\to -2}f(x) \qquad \text{(b)}\ \lim_{x\to 0}f(x) \qquad \text{(c)}\ \lim_{x\to 3}f(x)$$

***Solution (a).*** We will determine the stated two-sided limit by first considering the corresponding one-sided limits. For each one-sided limit, we must use that part of the formula that is applicable on the interval over which $x$ varies. For example, as $x$ approaches $-2$ from the left, the applicable part of the formula is

$$f(x)=\frac{1}{x+2}$$

and as $x$ approaches $-2$ from the right, the applicable part of the formula near $-2$ is

$$f(x)=x^2-5$$

Thus,

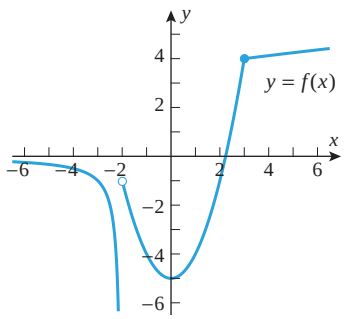
$$\lim_{x\to -2^-}f(x)=\lim_{x\to -2^-}\frac{1}{x+2}=-\infty$$

$$\lim_{x\to -2^+}f(x)=\lim_{x\to -2^+}(x^2-5)=(-2)^2-5=-1$$

from which it follows that $\lim_{x\to -2}f(x)$ does not exist.

***Solution (b).*** The applicable part of the formula is $f(x)=x^2-5$ on both sides of 0, so there is no need to consider one-sided limits here. We see directly that

$$\lim_{x\to 0}f(x)=\lim_{x\to 0}(x^2-5)=0^2-5=-5$$



▲ Figure 1.2.5

***Solution (c).*** Using the applicable parts of the formula for $f(x)$, we obtain

$$\lim_{x\to 3^-}f(x)=\lim_{x\to 3^-}(x^2-5)=3^2-5=4$$

$$\lim_{x\to 3^+}f(x)=\lim_{x\to 3^+}\sqrt{x+13}=\sqrt{\lim_{x\to 3^+}(x+13)}=\sqrt{3+13}=4$$

Since the one-sided limits are equal, we have

$$\lim_{x\to 3}f(x)=4$$

We note that the limit calculations in parts (a), (b), and (c) are consistent with the graph of $f$ shown in Figure 1.2.5. ◀

## ✔ QUICK CHECK EXERCISES 1.2 (See page 88 for answers.)

**1.** In each part, find the limit by inspection.

(a) $\lim_{x \to 8} 7 =$ _____ (b) $\lim_{y \to 3^+} 12y =$ _____

(c) $\lim_{x \to 0^-} \dfrac{x}{|x|} =$ _____ (d) $\lim_{w \to 5} \dfrac{w}{|w|} =$ _____

$$f(x) = \begin{cases} x + 1, & x \le 1 \\ x - 1, & x > 1 \end{cases}$$

Find the limits that exist.

(a) $\lim_{x \to 1^-} f(x) =$ _____

(b) $\lim_{x \to 1^+} f(x) =$ _____

(c) $\lim_{x \to 1} f(x) =$ _____

## EXERCISE SET 1.2

**1.** Given that

$$\lim_{x \to a} f(x) = 2, \quad \lim_{x \to a} g(x) = -4, \quad \lim_{x \to a} h(x) = 0$$

find the limits.

(a) $\lim_{x \to a} [f(x) + 2g(x)]$

(b) $\lim_{x \to a} [h(x) - 3g(x) + 1]$

(c) $\lim_{x \to a} [f(x)g(x)]$ (d) $\lim_{x \to a} [g(x)]^2$

(e) $\lim_{x \to a} \sqrt[3]{6 + f(x)}$ (f) $\lim_{x \to a} \dfrac{2}{g(x)}$

**2.** Use the graphs of $f$ and $g$ in the accompanying figure to find the limits that exist. If the limit does not exist, explain why.

(a) $\lim_{x \to 2} [f(x) + g(x)]$ (b) $\lim_{x \to 0} [f(x) + g(x)]$

(c) $\lim_{x \to 0^+} [f(x) + g(x)]$ (d) $\lim_{x \to 0^-} [f(x) + g(x)]$

(e) $\lim_{x \to 2} \dfrac{f(x)}{1 + g(x)}$ (f) $\lim_{x \to 2} \dfrac{1 + g(x)}{f(x)}$

(g) $\lim_{x \to 0^+} \sqrt{f(x)}$ (h) $\lim_{x \to 0^-} \sqrt{f(x)}$

**29.** $\lim_{x \to 9} \dfrac{x - 9}{\sqrt{x} - 3}$

**30.** $\lim_{y \to 4} \dfrac{4 - y}{2 - \sqrt{y}}$

**31.** Let

$$f(x) = \begin{cases} x - 1, & x \le 3 \\ 3x - 7, & x > 3 \end{cases}$$

(cont.)

Find

(a) $\lim_{x\to 3^-} f(x)$ (b) $\lim_{x\to 3^+} f(x)$ (c) $\lim_{x\to 3} f(x)$.

**32.** Let

$$g(t)=\begin{cases} t-2, & t<0 \\ t^2, & 0\le t\le 2 \\ 2t, & t>2 \end{cases}$$

Find

(a) $\lim_{t\to 0} g(t)$ (b) $\lim_{t\to 1} g(t)$ (c) $\lim_{t\to 2} g(t)$.

**33–36 True–False** Determine whether the statement is true or false. Explain your answer.

**33.** If $\lim_{x\to a} f(x)$ and $\lim_{x\to a} g(x)$ exist, then so does $\lim_{x\to a}[f(x)+g(x)]$.

**34.** If $\lim_{x\to a} g(x)=0$ and $\lim_{x\to a} f(x)$ exists, then $\lim_{x\to a}[f(x)/g(x)]$ does not exist.

**35.** If $\lim_{x\to a} f(x)$ and $\lim_{x\to a} g(x)$ both exist and are equal, then $\lim_{x\to a}[f(x)/g(x)]=1$.

**36.** If $f(x)$ is a rational function and $x=a$ is in the domain of $f$, then $\lim_{x\to a} f(x)=f(a)$.

**37–38** First rationalize the numerator and then find the limit.

**37.** $\lim_{x\to 0}\dfrac{\sqrt{x+4}-2}{x}$ **38.** $\lim_{x\to 0}\dfrac{\sqrt{x^2+4}-2}{x}$

**39.** Let

$$f(x)=\frac{x^3-1}{x-1}$$

(a) Find $\lim_{x\to 1} f(x)$.

(b) Sketch the graph of $y=f(x)$.

**40.** Let

$$f(x)=\begin{cases} \dfrac{x^2-9}{x+3}, & x\ne -3 \\ k, & x=-3 \end{cases}$$

(a) Find $k$ so that $f(-3)=\lim_{x\to -3} f(x)$.

(b) With $k$ assigned the value $\lim_{x\to -3} f(x)$, show that $f(x)$ can be expressed as a polynomial.

**FOCUS ON CONCEPTS**

**41.** (a) Explain why the following calculation is incorrect.

$$\lim_{x\to 0^+}\left(\frac{1}{x}-\frac{1}{x^2}\right)=\lim_{x\to 0^+}\frac{1}{x}-\lim_{x\to 0^+}\frac{1}{x^2}$$
$$=+\infty-(+\infty)=0$$

(b) Show that $\lim_{x\to 0^+}\left(\dfrac{1}{x}-\dfrac{1}{x^2}\right)=-\infty$.

**42.** (a) Explain why the following argument is incorrect.

$$\lim_{x\to 0}\left(\frac{1}{x}-\frac{2}{x^2+2x}\right)=\lim_{x\to 0}\frac{1}{x}\left(1-\frac{2}{x+2}\right)$$
$$=\infty\cdot 0=0$$

(b) Show that $\lim_{x\to 0}\left(\dfrac{1}{x}-\dfrac{2}{x^2+2x}\right)=\dfrac{1}{2}$.

**43.** Find all values of $a$ such that

$$\lim_{x\to 1}\left(\frac{1}{x-1}-\frac{a}{x^2-1}\right)$$

exists and is finite.

**44.** (a) Explain informally why

$$\lim_{x\to 0^-}\left(\frac{1}{x}+\frac{1}{x^2}\right)=+\infty$$

(b) Verify the limit in part (a) algebraically.

**45.** Let $p(x)$ and $q(x)$ be polynomials, with $q(x_0)=0$. Discuss the behavior of the graph of $y=p(x)/q(x)$ in the vicinity of $x=x_0$. Give examples to support your conclusions.

**46.** Suppose that $f$ and $g$ are two functions such that $\lim_{x\to a} f(x)$ exists but $\lim_{x\to a}[f(x)+g(x)]$ does not exist. Use Theorem 1.2.2. to prove that $\lim_{x\to a} g(x)$ does not exist.

**47.** Suppose that $f$ and $g$ are two functions such that both $\lim_{x\to a} f(x)$ and $\lim_{x\to a}[f(x)+g(x)]$ exist. Use Theorem 1.2.2 to prove that $\lim_{x\to a} g(x)$ exists.

**48.** Suppose that $f$ and $g$ are two functions such that

$$\lim_{x\to a} g(x)=0 \quad \text{and} \quad \lim_{x\to a}\frac{f(x)}{g(x)}$$

exists. Use Theorem 1.2.2 to prove that $\lim_{x\to a} f(x)=0$.

**49. Writing** According to Newton's Law of Universal Gravitation, the gravitational force of attraction between two masses is inversely proportional to the square of the distance between them. What results of this section are useful in describing the gravitational force of attraction between the masses as they get closer and closer together?

**50. Writing** Suppose that $f$ and $g$ are two functions that are equal except at a finite number of points and that $a$ denotes a real number. Explain informally why both

$$\lim_{x\to a} f(x) \quad \text{and} \quad \lim_{x\to a} g(x)$$

exist and are equal, or why both limits fail to exist. Write a short paragraph that explains the relationship of this result to the use of "algebraic simplification" in the evaluation of a limit.

# 1.3 LIMITS AT INFINITY; END BEHAVIOR OF A FUNCTION

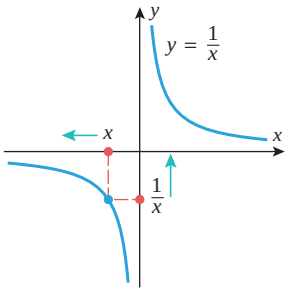
*Up to now we have been concerned with limits that describe the behavior of a function $f(x)$ as $x$ approaches some real number $a$. In this section we will be concerned with the behavior of $f(x)$ as $x$ increases or decreases without bound.*

## LIMITS AT INFINITY AND HORIZONTAL ASYMPTOTES

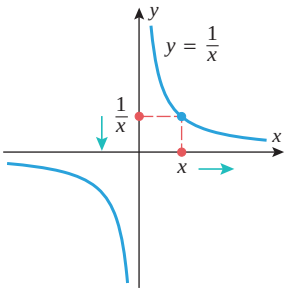
If the values of a variable $x$ increase without bound, then we write $x \to +\infty$, and if the values of $x$ decrease without bound, then we write $x \to -\infty$. The behavior of a function $f(x)$ as $x$ increases without bound or decreases without bound is sometimes called the ***end behavior*** of the function. For example,

$$\lim_{x \to -\infty} \frac{1}{x} = 0 \quad \text{and} \quad \lim_{x \to +\infty} \frac{1}{x} = 0 \tag{1–2}$$

are illustrated numerically in Table 1.3.1 and geometrically in Figure 1.3.1.



$\lim_{x \to -\infty} \frac{1}{x} = 0$



$\lim_{x \to +\infty} \frac{1}{x} = 0$

▲ **Figure 1.3.1**

**Table 1.3.1**

| | VALUES | | | | | | CONCLUSION |
|---|---|---|---|---|---|---|---|
| $x$ | $-1$ | $-10$ | $-100$ | $-1000$ | $-10{,}000$ | $\cdots$ | As $x \to -\infty$ the value of $1/x$ |
| $1/x$ | $-1$ | $-0.1$ | $-0.01$ | $-0.001$ | $-0.0001$ | $\cdots$ | increases toward zero. |
| $x$ | 1 | 10 | 100 | 1000 | 10,000 | $\cdots$ | As $x \to +\infty$ the value of $1/x$ |
| $1/x$ | 1 | 0.1 | 0.01 | 0.001 | 0.0001 | $\cdots$ | decreases toward zero. |

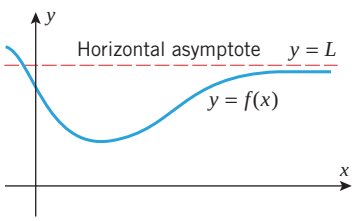
In general, we will use the following notation.

**1.3.1 LIMITS AT INFINITY (AN INFORMAL VIEW)** If the values of $f(x)$ eventually get as close as we like to a number $L$ as $x$ increases without bound, then we write

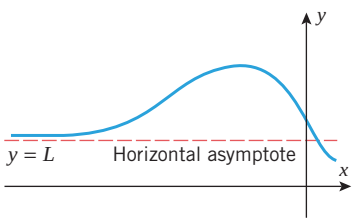
$$\lim_{x \to +\infty} f(x) = L \quad \text{or} \quad f(x) \to L \text{ as } x \to +\infty \tag{3}$$

Similarly, if the values of $f(x)$ eventually get as close as we like to a number $L$ as $x$ decreases without bound, then we write

$$\lim_{x \to -\infty} f(x) = L \quad \text{or} \quad f(x) \to L \text{ as } x \to -\infty \tag{4}$$



$\lim_{x \to +\infty} f(x) = L$



$\lim_{x \to -\infty} f(x) = L$

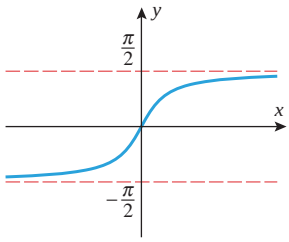
▲ **Figure 1.3.2**

Figure 1.3.2 illustrates the end behavior of a function $f$ when

$$\lim_{x \to +\infty} f(x) = L \quad \text{or} \quad \lim_{x \to -\infty} f(x) = L$$

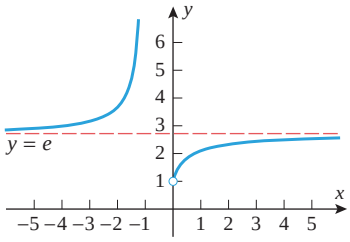
In the first case the graph of $f$ eventually comes as close as we like to the line $y = L$ as $x$ increases without bound, and in the second case it eventually comes as close as we like to the line $y = L$ as $x$ decreases without bound. If either limit holds, we call the line $y = L$ a ***horizontal asymptote*** for the graph of $f$.

► **Example 1** It follows from (1) and (2) that $y = 0$ is a horizontal asymptote for the graph of $f(x) = 1/x$ in both the positive and negative directions. This is consistent with the graph of $y = 1/x$ shown in Figure 1.3.1. ◄



$y = \tan^{-1} x$

▲ Figure 1.3.3



$y = \left(1 + \frac{1}{x}\right)^x$

▲ Figure 1.3.4

**▶ Example 2** Figure 1.3.3 is the graph of $f(x) = \tan^{-1} x$. As suggested by this graph,

$$\lim_{x \to +\infty} \tan^{-1} x = \frac{\pi}{2} \quad \text{and} \quad \lim_{x \to -\infty} \tan^{-1} x = -\frac{\pi}{2} \tag{5–6}$$

so the line $y = \pi/2$ is a horizontal asymptote for $f$ in the positive direction and the line $y = -\pi/2$ is a horizontal asymptote in the negative direction. ◀

**▶ Example 3** Figure 1.3.4 is the graph of $f(x) = (1 + 1/x)^x$. As suggested by this graph,

$$\lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x = e \quad \text{and} \quad \lim_{x \to -\infty} \left(1 + \frac{1}{x}\right)^x = e \tag{7–8}$$

so the line $y = e$ is a horizontal asymptote for $f$ in both the positive and negative directions. ◀

## LIMIT LAWS FOR LIMITS AT INFINITY

It can be shown that the limit laws in Theorem 1.2.2 carry over without change to limits at $+\infty$ and $-\infty$. Moreover, it follows by the same argument used in Section 1.2 that if $n$ is a positive integer, then

$$\lim_{x \to +\infty} (f(x))^n = \left(\lim_{x \to +\infty} f(x)\right)^n \qquad \lim_{x \to -\infty} (f(x))^n = \left(\lim_{x \to -\infty} f(x)\right)^n \tag{9–10}$$

provided the indicated limit of $f(x)$ exists. It also follows that constants can be moved through the limit symbols for limits at infinity:

$$\lim_{x \to +\infty} kf(x) = k \lim_{x \to +\infty} f(x) \qquad \lim_{x \to -\infty} kf(x) = k \lim_{x \to -\infty} f(x) \tag{11–12}$$

provided the indicated limit of $f(x)$ exists.

Finally, if $f(x) = k$ is a constant function, then the values of $f$ do not change as $x \to +\infty$ or as $x \to -\infty$, so

$$\lim_{x \to +\infty} k = k \qquad \lim_{x \to -\infty} k = k \tag{13–14}$$

**▶ Example 4**

(a) It follows from (1), (2), (9), and (10) that if $n$ is a positive integer, then

$$\lim_{x \to +\infty} \frac{1}{x^n} = \left(\lim_{x \to +\infty} \frac{1}{x}\right)^n = 0 \quad \text{and} \quad \lim_{x \to -\infty} \frac{1}{x^n} = \left(\lim_{x \to -\infty} \frac{1}{x}\right)^n = 0$$

(b) It follows from (7) and the extension of Theorem 1.2.2(e) to the case $x \to +\infty$ that

$$\lim_{x \to +\infty} \left(1 + \frac{1}{2x}\right)^x = \lim_{x \to +\infty} \left[\left(1 + \frac{1}{2x}\right)^{2x}\right]^{1/2}$$

$$= \left[\lim_{x \to +\infty} \left(1 + \frac{1}{2x}\right)^{2x}\right]^{1/2} = e^{1/2} = \sqrt{e}$$ ◀

## INFINITE LIMITS AT INFINITY

Limits at infinity, like limits at a real number $a$, can fail to exist for various reasons. One such possibility is that the values of $f(x)$ increase or decrease without bound as $x \to +\infty$ or as $x \to -\infty$. We will use the following notation to describe this situation.

**1.3.2 INFINITE LIMITS AT INFINITY (AN INFORMAL VIEW)** If the values of $f(x)$ increase without bound as $x \to +\infty$ or as $x \to -\infty$, then we write

$$\lim_{x \to +\infty} f(x) = +\infty \quad \text{or} \quad \lim_{x \to -\infty} f(x) = +\infty$$

as appropriate; and if the values of $f(x)$ decrease without bound as $x \to +\infty$ or as $x \to -\infty$, then we write

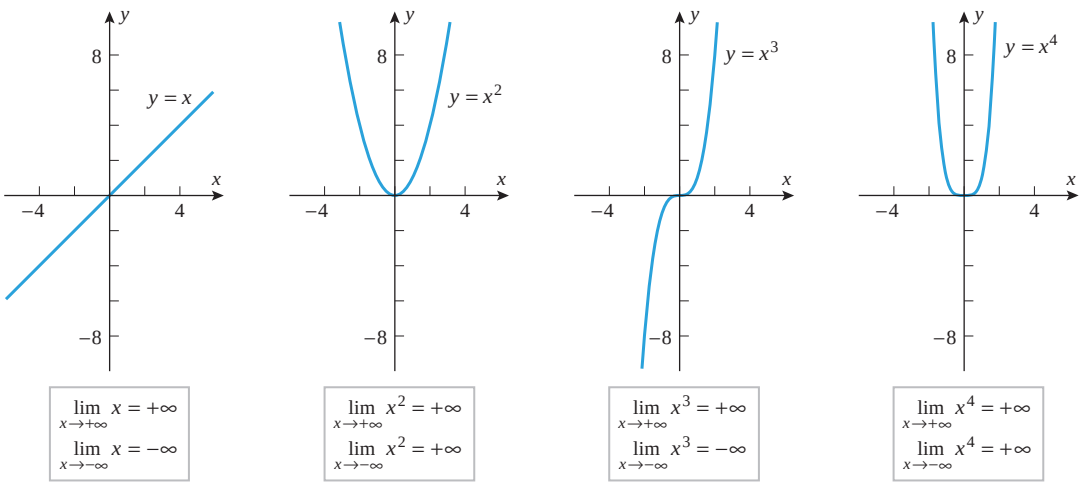
$$\lim_{x \to +\infty} f(x) = -\infty \quad \text{or} \quad \lim_{x \to -\infty} f(x) = -\infty$$

as appropriate.

## LIMITS OF $x^n$ AS $x \to \pm\infty$

Figure 1.3.5 illustrates the end behavior of the polynomials $x^n$ for $n = 1, 2, 3$, and 4. These are special cases of the following general results:

$$\lim_{x \to +\infty} x^n = +\infty, \quad n = 1, 2, 3, \ldots \qquad \lim_{x \to -\infty} x^n = \begin{cases} -\infty, & n = 1, 3, 5, \ldots \\ +\infty, & n = 2, 4, 6, \ldots \end{cases} \tag{15–16}$$



▲ **Figure 1.3.5**

Multiplying $x^n$ by a positive real number does not affect limits (15) and (16), but multiplying by a negative real number reverses the sign.

**► Example 5**

$$\lim_{x \to +\infty} 2x^5 = +\infty, \qquad \lim_{x \to -\infty} 2x^5 = -\infty$$

$$\lim_{x \to +\infty} -7x^6 = -\infty, \qquad \lim_{x \to -\infty} -7x^6 = -\infty \quad \blacktriangleleft$$

## LIMITS OF POLYNOMIALS AS $x \to \pm\infty$

There is a useful principle about polynomials which, expressed informally, states:

*The end behavior of a polynomial matches the end behavior of its highest degree term.*

More precisely, if $c_n \neq 0$, then

$$\lim_{x \to -\infty} (c_0 + c_1 x + \cdots + c_n x^n) = \lim_{x \to -\infty} c_n x^n \tag{17}$$

$$\lim_{x \to +\infty} (c_0 + c_1 x + \cdots + c_n x^n) = \lim_{x \to +\infty} c_n x^n \tag{18}$$

We can motivate these results by factoring out the highest power of $x$ from the polynomial and examining the limit of the factored expression. Thus,

$$c_0 + c_1 x + \cdots + c_n x^n = x^n \left( \frac{c_0}{x^n} + \frac{c_1}{x^{n-1}} + \cdots + c_n \right)$$

As $x \to -\infty$ or $x \to +\infty$, it follows from Example 4(a) that all of the terms with positive powers of $x$ in the denominator approach 0, so (17) and (18) are certainly plausible.

**▶ Example 6**

$$\lim_{x \to -\infty} (7x^5 - 4x^3 + 2x - 9) = \lim_{x \to -\infty} 7x^5 = -\infty$$

$$\lim_{x \to -\infty} (-4x^8 + 17x^3 - 5x + 1) = \lim_{x \to -\infty} -4x^8 = -\infty \quad \blacktriangleleft$$

## LIMITS OF RATIONAL FUNCTIONS AS $x \to \pm\infty$

One technique for determining the end behavior of a rational function is to divide each term in the numerator and denominator by the highest power of $x$ that occurs in the denominator, after which the limiting behavior can be determined using results we have already established. Here are some examples.

**▶ Example 7** Find $\lim_{x \to +\infty} \dfrac{3x + 5}{6x - 8}$.

***Solution.*** Divide each term in the numerator and denominator by the highest power of $x$ that occurs in the denominator, namely, $x^1 = x$. We obtain

$$\lim_{x \to +\infty} \frac{3x + 5}{6x - 8} = \lim_{x \to +\infty} \frac{3 + \dfrac{5}{x}}{6 - \dfrac{8}{x}}$$ Divide each term by $x$.

$$= \frac{\lim\limits_{x \to +\infty} \left(3 + \dfrac{5}{x}\right)}{\lim\limits_{x \to +\infty} \left(6 - \dfrac{8}{x}\right)}$$ Limit of a quotient is the quotient of the limits.

$$= \frac{\lim\limits_{x \to +\infty} 3 + \lim\limits_{x \to +\infty} \dfrac{5}{x}}{\lim\limits_{x \to +\infty} 6 - \lim\limits_{x \to +\infty} \dfrac{8}{x}}$$ Limit of a sum is the sum of the limits.

$$= \frac{3 + 5 \lim\limits_{x \to +\infty} \dfrac{1}{x}}{6 - 8 \lim\limits_{x \to +\infty} \dfrac{1}{x}} = \frac{3 + 0}{6 - 0} = \frac{1}{2}$$ A constant can be moved through a limit symbol; Formulas (2) and (13). $\blacktriangleleft$

▶ **Example 8** Find

$$\text{(a)}\ \lim_{x\to-\infty}\frac{4x^2-x}{2x^3-5} \qquad \text{(b)}\ \lim_{x\to+\infty}\frac{5x^3-2x^2+1}{1-3x}$$

***Solution (a).*** Divide each term in the numerator and denominator by the highest power of $x$ that occurs in the denominator, namely, $x^3$. We obtain

$$\lim_{x\to-\infty}\frac{4x^2-x}{2x^3-5}=\lim_{x\to-\infty}\frac{\dfrac{4}{x}-\dfrac{1}{x^2}}{2-\dfrac{5}{x^3}}$$

Divide each term by $x^3$.

$$=\frac{\lim\limits_{x\to-\infty}\left(\dfrac{4}{x}-\dfrac{1}{x^2}\right)}{\lim\limits_{x\to-\infty}\left(2-\dfrac{5}{x^3}\right)}$$

Limit of a quotient is the quotient of the limits.

$$=\frac{\lim\limits_{x\to-\infty}\dfrac{4}{x}-\lim\limits_{x\to-\infty}\dfrac{1}{x^2}}{\lim\limits_{x\to-\infty}2-\lim\limits_{x\to-\infty}\dfrac{5}{x^3}}$$

Limit of a difference is the difference of the limits.

$$=\frac{4\lim\limits_{x\to-\infty}\dfrac{1}{x}-\lim\limits_{x\to-\infty}\dfrac{1}{x^2}}{2-5\lim\limits_{x\to-\infty}\dfrac{1}{x^3}}=\frac{0-0}{2-0}=0$$

A constant can be moved through a limit symbol; Formula (14) and Example 4.

***Solution (b).*** Divide each term in the numerator and denominator by the highest power of $x$ that occurs in the denominator, namely, $x^1=x$. We obtain

$$\lim_{x\to+\infty}\frac{5x^3-2x^2+1}{1-3x}=\lim_{x\to+\infty}\frac{5x^2-2x+\dfrac{1}{x}}{\dfrac{1}{x}-3} \tag{19}$$

In this case we cannot argue that the limit of the quotient is the quotient of the limits because the limit of the numerator does not exist. However, we have

$$\lim_{x\to+\infty}5x^2-2x=+\infty,\qquad \lim_{x\to+\infty}\frac{1}{x}=0,\qquad \lim_{x\to+\infty}\left(\frac{1}{x}-3\right)=-3$$

Thus, the numerator on the right side of (19) approaches $+\infty$ and the denominator has a finite *negative* limit. We conclude from this that the quotient approaches $-\infty$; that is,

$$\lim_{x\to+\infty}\frac{5x^3-2x^2+1}{1-3x}=\lim_{x\to+\infty}\frac{5x^2-2x+\dfrac{1}{x}}{\dfrac{1}{x}-3}=-\infty \quad ◀$$

## A QUICK METHOD FOR FINDING LIMITS OF RATIONAL FUNCTIONS AS $x\to+\infty$ OR $x\to-\infty$

Since the end behavior of a polynomial matches the end behavior of its highest degree term, one can reasonably conclude:

*The end behavior of a rational function matches the end behavior of the quotient of the highest degree term in the numerator divided by the highest degree term in the denominator.*

▶ **Example 9** Use the preceding observation to compute the limits in Examples 7 and 8.

***Solution.***

$$\lim_{x\to+\infty}\frac{3x+5}{6x-8}=\lim_{x\to+\infty}\frac{3x}{6x}=\lim_{x\to+\infty}\frac{1}{2}=\frac{1}{2}$$

$$\lim_{x\to-\infty}\frac{4x^2-x}{2x^3-5}=\lim_{x\to-\infty}\frac{4x^2}{2x^3}=\lim_{x\to-\infty}\frac{2}{x}=0$$

$$\lim_{x\to+\infty}\frac{5x^3-2x^2+1}{1-3x}=\lim_{x\to+\infty}\frac{5x^3}{(-3x)}=\lim_{x\to+\infty}\left(-\frac{5}{3}x^2\right)=-\infty \quad \blacktriangleleft$$

## LIMITS INVOLVING RADICALS

▶ **Example 10** Find

$$\text{(a)}\ \lim_{x\to+\infty}\frac{\sqrt{x^2+2}}{3x-6} \qquad \text{(b)}\ \lim_{x\to-\infty}\frac{\sqrt{x^2+2}}{3x-6}$$

In both parts it would be helpful to manipulate the function so that the powers of $x$ are transformed to powers of $1/x$. This can be achieved in both cases by dividing the numerator and denominator by $|x|$ and using the fact that $\sqrt{x^2}=|x|$.

***Solution (a).*** As $x\to+\infty$, the values of $x$ under consideration are positive, so we can replace $|x|$ by $x$ where helpful. We obtain

$$\lim_{x\to+\infty}\frac{\sqrt{x^2+2}}{3x-6}=\lim_{x\to+\infty}\frac{\dfrac{\sqrt{x^2+2}}{|x|}}{\dfrac{3x-6}{|x|}}=\lim_{x\to+\infty}\frac{\dfrac{\sqrt{x^2+2}}{\sqrt{x^2}}}{\dfrac{3x-6}{x}}$$

$$=\lim_{x\to+\infty}\frac{\sqrt{1+\dfrac{2}{x^2}}}{3-\dfrac{6}{x}}=\frac{\lim\limits_{x\to+\infty}\sqrt{1+\dfrac{2}{x^2}}}{\lim\limits_{x\to+\infty}\left(3-\dfrac{6}{x}\right)}$$

$$=\frac{\sqrt{\lim\limits_{x\to+\infty}\left(1+\dfrac{2}{x^2}\right)}}{\lim\limits_{x\to+\infty}\left(3-\dfrac{6}{x}\right)}=\frac{\sqrt{\left(\lim\limits_{x\to+\infty}1\right)+\left(2\lim\limits_{x\to+\infty}\dfrac{1}{x^2}\right)}}{\left(\lim\limits_{x\to+\infty}3\right)-\left(6\lim\limits_{x\to+\infty}\dfrac{1}{x}\right)}$$

$$=\frac{\sqrt{1+(2\cdot 0)}}{3-(6\cdot 0)}=\frac{1}{3}$$

**TECHNOLOGY MASTERY**

It follows from Example 10 that the function

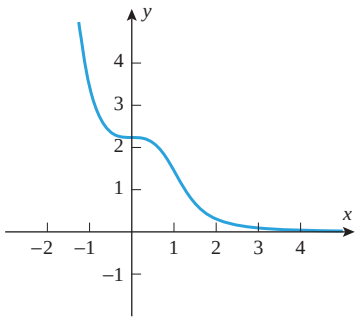
$$f(x)=\frac{\sqrt{x^2+2}}{3x-6}$$

has an asymptote of $y=\frac{1}{3}$ in the positive direction and an asymptote of $y=-\frac{1}{3}$ in the negative direction. Confirm this using a graphing utility.

***Solution (b).*** As $x\to-\infty$, the values of $x$ under consideration are negative, so we can replace $|x|$ by $-x$ where helpful. We obtain

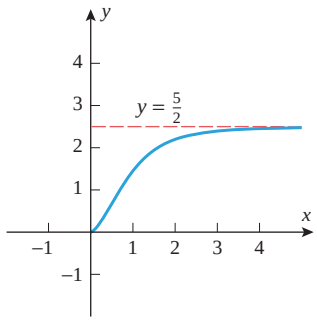
$$\lim_{x\to-\infty}\frac{\sqrt{x^2+2}}{3x-6}=\lim_{x\to-\infty}\frac{\dfrac{\sqrt{x^2+2}}{|x|}}{\dfrac{3x-6}{|x|}}=\lim_{x\to-\infty}\frac{\dfrac{\sqrt{x^2+2}}{\sqrt{x^2}}}{\dfrac{3x-6}{(-x)}}$$

$$=\lim_{x\to-\infty}\frac{\sqrt{1+\dfrac{2}{x^2}}}{-3+\dfrac{6}{x}}=-\frac{1}{3} \quad \blacktriangleleft$$



$y = \sqrt{x^6 + 5} - x^3$

(a)

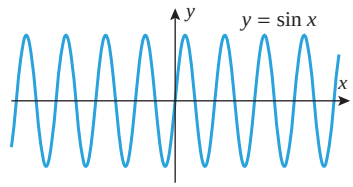


$y = \sqrt{x^6 + 5x^3} - x^3,\ x \geq 0$

(b)

▲ **Figure 1.3.6**

We noted in Section 1.1 that the standard rules of algebra do not apply to the symbols $+\infty$ and $-\infty$. Part (b) of Example 11 illustrates this. The terms $\sqrt{x^6 + 5x^3}$ and $x^3$ both approach $+\infty$ as $x \to +\infty$, but their difference does not approach 0.



There is no limit as $x \to +\infty$ or $x \to -\infty$.

▲ **Figure 1.3.7**

▶ **Example 11** Find

$$\text{(a)}\ \lim_{x \to +\infty} (\sqrt{x^6 + 5} - x^3) \qquad \text{(b)}\ \lim_{x \to +\infty} (\sqrt{x^6 + 5x^3} - x^3)$$

***Solution.*** Graphs of the functions $f(x) = \sqrt{x^6 + 5} - x^3$, and $g(x) = \sqrt{x^6 + 5x^3} - x^3$ for $x \geq 0$, are shown in Figure 1.3.6. From the graphs we might conjecture that the requested limits are 0 and $\frac{5}{2}$, respectively. To confirm this, we treat each function as a fraction with a denominator of 1 and rationalize the numerator.

$$\lim_{x \to +\infty} (\sqrt{x^6 + 5} - x^3) = \lim_{x \to +\infty} (\sqrt{x^6 + 5} - x^3) \left( \frac{\sqrt{x^6 + 5} + x^3}{\sqrt{x^6 + 5} + x^3} \right)$$

$$= \lim_{x \to +\infty} \frac{(x^6 + 5) - x^6}{\sqrt{x^6 + 5} + x^3} = \lim_{x \to +\infty} \frac{5}{\sqrt{x^6 + 5} + x^3}$$

$$= \lim_{x \to +\infty} \frac{\frac{5}{x^3}}{\sqrt{1 + \frac{5}{x^6}} + 1} \qquad \sqrt{x^6} = x^3 \text{ for } x > 0$$

$$= \frac{0}{\sqrt{1 + 0} + 1} = 0$$

$$\lim_{x \to +\infty} (\sqrt{x^6 + 5x^3} - x^3) = \lim_{x \to +\infty} (\sqrt{x^6 + 5x^3} - x^3) \left( \frac{\sqrt{x^6 + 5x^3} + x^3}{\sqrt{x^6 + 5x^3} + x^3} \right)$$

$$= \lim_{x \to +\infty} \frac{(x^6 + 5x^3) - x^6}{\sqrt{x^6 + 5x^3} + x^3} = \lim_{x \to +\infty} \frac{5x^3}{\sqrt{x^6 + 5x^3} + x^3}$$

$$= \lim_{x \to +\infty} \frac{5}{\sqrt{1 + \frac{5}{x^3}} + 1} \qquad \sqrt{x^6} = x^3 \text{ for } x > 0$$

$$= \frac{5}{\sqrt{1 + 0} + 1} = \frac{5}{2}$$ ◀

## END BEHAVIOR OF TRIGONOMETRIC, EXPONENTIAL, AND LOGARITHMIC FUNCTIONS

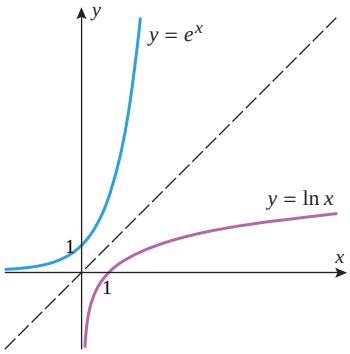
Consider the function $f(x) = \sin x$ that is graphed in Figure 1.3.7. For this function the limits as $x \to +\infty$ and as $x \to -\infty$ fail to exist not because $f(x)$ increases or decreases without bound, but rather because the values vary between $-1$ and 1 without approaching some specific real number. In general, the trigonometric functions fail to have limits as $x \to +\infty$ and as $x \to -\infty$ because of periodicity. There is no specific notation to denote this kind of behavior.

In Section 0.5 we showed that the functions $e^x$ and $\ln x$ both increase without bound as $x \to +\infty$ (Figures 0.5.8 and 0.5.9). Thus, in limit notation we have

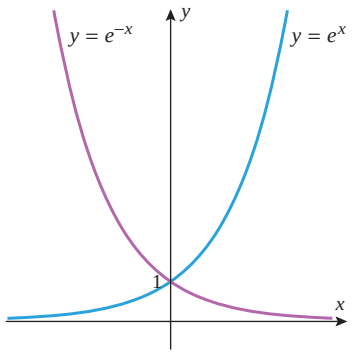
$$\lim_{x \to +\infty} \ln x = +\infty \qquad \lim_{x \to +\infty} e^x = +\infty \tag{20–21}$$

For reference, we also list the following limits, which are consistent with the graphs in Figure 1.3.8:

$$\lim_{x \to -\infty} e^x = 0 \qquad \lim_{x \to 0^+} \ln x = -\infty \tag{22–23}$$



▲ Figure 1.3.8



▲ Figure 1.3.9

Finally, the following limits can be deduced by noting that the graph of $y = e^{-x}$ is the reflection about the $y$-axis of the graph of $y = e^x$ (Figure 1.3.9).

$$\lim_{x \to +\infty} e^{-x} = 0 \qquad \lim_{x \to -\infty} e^{-x} = +\infty \tag{24–25}$$

## ✔ QUICK CHECK EXERCISES 1.3 (See page 100 for answers.)

**1.** Find the limits.

(a) $\lim_{x \to -\infty} (3 - x) =$ _____

(b) $\lim_{x \to +\infty} \left(5 - \frac{1}{x}\right) =$ _____

(c) $\lim_{x \to +\infty} \ln\left(\frac{1}{x}\right) =$ _____

(d) $\lim_{x \to +\infty} \frac{1}{e^x} =$ _____

**2.** Find the limits that exist.

(a) $\lim_{x \to -\infty} \frac{2x^2 + x}{4x^2 - 3} =$ _____

(b) $\lim_{x \to +\infty} \frac{1}{2 + \sin x} =$ _____

(c) $\lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x =$ _____

**3.** Given that

$$\lim_{x \to +\infty} f(x) = 2 \quad \text{and} \quad \lim_{x \to +\infty} g(x) = -3$$

find the limits that exist.

(a) $\lim_{x \to +\infty} [3f(x) - g(x)] =$ _____

(b) $\lim_{x \to +\infty} \frac{f(x)}{g(x)} =$ _____

(c) $\lim_{x \to +\infty} \frac{2f(x) + 3g(x)}{3f(x) + 2g(x)} =$ _____

(d) $\lim_{x \to +\infty} \sqrt{10 - f(x)g(x)} =$ _____

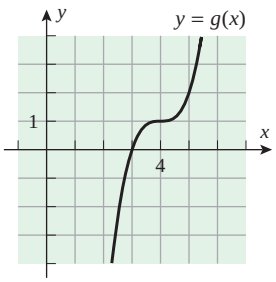
**4.** Consider the graphs of $1/x$, $\sin x$, $\ln x$, $e^x$, and $e^{-x}$. Which of these graphs has a horizontal asymptote?

## EXERCISE SET 1.3 Graphing Utility

**1–4** In these exercises, make reasonable assumptions about the end behavior of the indicated function. ■

**1.** For the function $g$ graphed in the accompanying figure, find

(a) $\lim_{x \to -\infty} g(x)$ (b) $\lim_{x \to +\infty} g(x)$.

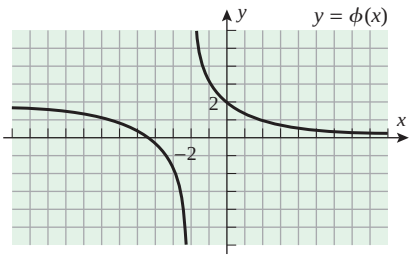


◀ Figure Ex-1

**2.** For the function $\phi$ graphed in the accompanying figure, find

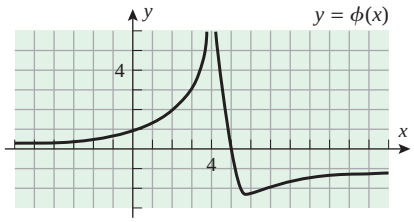
(a) $\lim_{x \to -\infty} \phi(x)$

(b) $\lim_{x \to +\infty} \phi(x)$.



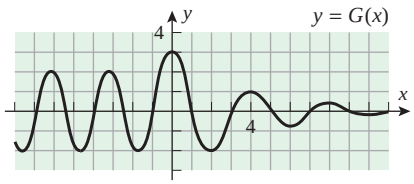
◀ Figure Ex-2

**3.** For the function $\phi$ graphed in the accompanying figure, find
(a) $\lim_{x\to-\infty}\phi(x)$ (b) $\lim_{x\to+\infty}\phi(x)$.



◀ **Figure Ex-3**

**4.** For the function $G$ graphed in the accompanying figure, find
(a) $\lim_{x\to-\infty}G(x)$ (b) $\lim_{x\to+\infty}G(x)$.



◀ **Figure Ex-4**

**5.** Given that

$$\lim_{x\to+\infty} f(x)=3,\quad \lim_{x\to+\infty} g(x)=-5,\quad \lim_{x\to+\infty} h(x)=0$$

find the limits that exist. If the limit does not exist, explain why.
(a) $\lim_{x\to+\infty}[f(x)+3g(x)]$
(b) $\lim_{x\to+\infty}[h(x)-4g(x)+1]$
(c) $\lim_{x\to+\infty}[f(x)g(x)]$ (d) $\lim_{x\to+\infty}[g(x)]^2$
(e) $\lim_{x\to+\infty}\sqrt[3]{5+f(x)}$ (f) $\lim_{x\to+\infty}\dfrac{3}{g(x)}$
(g) $\lim_{x\to+\infty}\dfrac{3h(x)+4}{x^2}$ (h) $\lim_{x\to+\infty}\dfrac{6f(x)}{5f(x)+3g(x)}$

**6.** Given that

$$\lim_{x\to-\infty} f(x)=7 \quad\text{and}\quad \lim_{x\to-\infty} g(x)=-6$$

find the limits that exist. If the limit does not exist, explain why.
(a) $\lim_{x\to-\infty}[2f(x)-g(x)]$ (b) $\lim_{x\to-\infty}[6f(x)+7g(x)]$
(c) $\lim_{x\to-\infty}[x^2+g(x)]$ (d) $\lim_{x\to-\infty}[x^2g(x)]$
(e) $\lim_{x\to-\infty}\sqrt[3]{f(x)g(x)}$ (f) $\lim_{x\to-\infty}\dfrac{g(x)}{f(x)}$
(g) $\lim_{x\to-\infty}\left[f(x)+\dfrac{g(x)}{x}\right]$ (h) $\lim_{x\to-\infty}\dfrac{xf(x)}{(2x+3)g(x)}$

**7.** (a) Complete the table and make a guess about the limit indicated.

$$f(x)=\tan^{-1}\left(\frac{1}{x}\right)\qquad \lim_{x\to0^+} f(x)$$

| $x$ | 0.1 | 0.01 | 0.001 | 0.0001 | 0.00001 | 0.000001 |
|---|---|---|---|---|---|---|
| $f(x)$ | | | | | | |

(b) Use Figure 1.3.3 to find the exact value of the limit in part (a).

**8.** Complete the table and make a guess about the limit indicated.

$$f(x)=x^{1/x}\qquad \lim_{x\to+\infty} f(x)$$

| $x$ | 10 | 100 | 1000 | 10,000 | 100,000 | 1,000,000 |
|---|---|---|---|---|---|---|
| $f(x)$ | | | | | | |

**9–40** Find the limits. ■

**9.** $\lim_{x\to+\infty}(1+2x-3x^5)$
**10.** $\lim_{x\to+\infty}(2x^3-100x+5)$
**11.** $\lim_{x\to+\infty}\sqrt{x}$
**12.** $\lim_{x\to-\infty}\sqrt{5-x}$
**13.** $\lim_{x\to+\infty}\dfrac{3x+1}{2x-5}$
**14.** $\lim_{x\to+\infty}\dfrac{5x^2-4x}{2x^2+3}$
**15.** $\lim_{y\to-\infty}\dfrac{3}{y+4}$

**36.** $\lim_{x\to-\infty}\dfrac{e^x+e^{-x}}{e^x-e^{-x}}$
**37.** $\lim_{x\to+\infty}\ln\left(\dfrac{2}{x^2}\right)$
**38.** $\lim_{x\to0^+}\ln\left(\dfrac{2}{x^2}\right)$
**39.** $\lim_{x\to+\infty}\dfrac{(x+1)^x}{x^x}$
**40.** $\lim_{x\to+\infty}\left(1+\dfrac{1}{x}\right)^{-x}$

**41–44 True–False** Determine whether the statement is true or false. Explain your answer. ■

**41.** We have $\lim_{x\to+\infty}\left(1+\dfrac{1}{x}\right)^{2x}=(1+0)^{+\infty}=1^{+\infty}=1$.

**42.** If $y = L$ is a horizontal asymptote for the curve $y = f(x)$, then

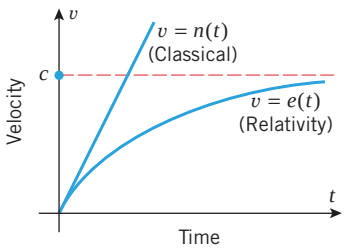
$$\lim_{x \to -\infty} f(x) = L \quad \text{and} \quad \lim_{x \to +\infty} f(x) = L$$

**43.** If $y = L$ is a horizontal asymptote for the curve $y = f(x)$, then it is possible for the graph of $f$ to intersect the line $y = L$ infinitely many times.

**44.** If a rational function $p(x)/q(x)$ has a horizontal asymptote, then the degree of $p(x)$ must equal the degree of $q(x)$.

**FOCUS ON CONCEPTS**

**45.** Assume that a particle is accelerated by a constant force. The two curves $v = n(t)$ and $v = e(t)$ in the accompanying figure provide velocity versus time curves for the particle as predicted by classical physics and by the special theory of relativity, respectively. The parameter $c$ represents the speed of light. Using the language of limits, describe the differences in the long-term predictions of the two theories.

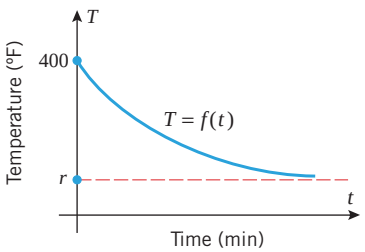


◀ **Figure Ex-45**

**46.** Let $T = f(t)$ denote the temperature of a baked potato $t$ minutes after it has been removed from a hot oven. The accompanying figure shows the temperature versus time curve for the potato, where $r$ is the temperature of the room.

(a) What is the physical significance of $\lim_{t \to 0^+} f(t)$?

(b) What is the physical significance of $\lim_{t \to +\infty} f(t)$?



◀ **Figure Ex-46**

**47.** Let

$$f(x) = \begin{cases} 2x^2 + 5, & x < 0 \\ \dfrac{3 - 5x^3}{1 + 4x + x^3}, & x \geq 0 \end{cases}$$

Find

(a) $\lim_{x \to -\infty} f(x)$ (b) $\lim_{x \to +\infty} f(x)$.

**48.** Let

$$g(t) = \begin{cases} \dfrac{2 + 3t}{5t^2 + 6}, & t < 1{,}000{,}000 \\ \dfrac{\sqrt{36t^2 - 100}}{5 - t}, & t > 1{,}000{,}000 \end{cases}$$

Find

(a) $\lim_{t \to -\infty} g(t)$ (b) $\lim_{t \to +\infty} g(t)$.

**49.** Discuss the limits of $p(x) = (1 - x)^n$ as $x \to +\infty$ and $x \to -\infty$ for positive integer values of $n$.

**50.** In each part, find examples of polynomials $p(x)$ and $q(x)$ that satisfy the stated condition and such that $p(x) \to +\infty$ and $q(x) \to +\infty$ as $x \to +\infty$.

(a) $\lim_{x \to +\infty} \dfrac{p(x)}{q(x)} = 1$ (b) $\lim_{x \to +\infty} \dfrac{p(x)}{q(x)} = 0$

(c) $\lim_{x \to +\infty} \dfrac{p(x)}{q(x)} = +\infty$ (d) $\lim_{x \to +\infty} [p(x) - q(x)] = 3$

**51.** (a) Do any of the trigonometric functions $\sin x$, $\cos x$, $\tan x$, $\cot x$, $\sec x$, and $\csc x$ have horizontal asymptotes?

(b) Do any of the trigonometric functions have vertical asymptotes? Where?

**52.** Find

$$\lim_{x \to +\infty} \frac{c_0 + c_1 x + \cdots + c_n x^n}{d_0 + d_1 x + \cdots + d_m x^m}$$

where $c_n \neq 0$ and $d_m \neq 0$. [*Hint:* Your answer will depend on whether $m < n$, $m = n$, or $m > n$.]

**FOCUS ON CONCEPTS**

**53–54** These exercises develop some versions of the ***substitution principle***, a useful tool for the evaluation of limits.

**53.** (a) Explain why we can evaluate $\lim_{x \to +\infty} e^{x^2}$ by making the substitution $t = x^2$ and writing

$$\lim_{x \to +\infty} e^{x^2} = \lim_{t \to +\infty} e^t = +\infty$$

(b) Suppose $g(x) \to +\infty$ as $x \to +\infty$. Given any function $f(x)$, explain why we can evaluate $\lim_{x \to +\infty} f[g(x)]$ by substituting $t = g(x)$ and writing

$$\lim_{x \to +\infty} f[g(x)] = \lim_{t \to +\infty} f(t)$$

(Here, "equality" is interpreted to mean that either both limits exist and are equal or that both limits fail to exist.)

(c) Why does the result in part (b) remain valid if $\lim_{x \to +\infty}$ is replaced everywhere by one of $\lim_{x \to -\infty}$, $\lim_{x \to c}$, $\lim_{x \to c^-}$, or $\lim_{x \to c^+}$?

**54.** (a) Explain why we can evaluate $\lim_{x \to +\infty} e^{-x^2}$ by making the substitution $t = -x^2$ and writing

$$\lim_{x \to +\infty} e^{-x^2} = \lim_{t \to -\infty} e^t = 0$$ *(cont.)*

(b) Suppose $g(x) \to -\infty$ as $x \to +\infty$. Given any function $f(x)$, explain why we can evaluate $\lim_{x\to+\infty} f[g(x)]$ by substituting $t = g(x)$ and writing

$$\lim_{x\to+\infty} f[g(x)] = \lim_{t\to-\infty} f(t)$$

(Here, "equality" is interpreted to mean that either both limits exist and are equal or that both limits fail to exist.)

(c) Why does the result in part (b) remain valid if $\lim_{x\to+\infty}$ is replaced everywhere by one of $\lim_{x\to-\infty}$, $\lim_{x\to c}$, $\lim_{x\to c^-}$, or $\lim_{x\to c^+}$?

**55–62** Evaluate the limit using an appropriate substitution. ■

**55.** $\lim_{x\to0^+} e^{1/x}$

**56.** $\lim_{x\to0^-} e^{1/x}$

**57.** $\lim_{x\to0^+} e^{\csc x}$

**58.** $\lim_{x\to0^-} e^{\csc x}$

**59.** $\lim_{x\to+\infty} \dfrac{\ln 2x}{\ln 3x}$ [*Hint:* $t = \ln x$]

**60.** $\lim_{x\to+\infty} [\ln(x^2 - 1) - \ln(x + 1)]$ [*Hint:* $t = x - 1$]

**61.** $\lim_{x\to+\infty} \left(1 - \dfrac{1}{x}\right)^{-x}$ [*Hint:* $t = -x$]

**62.** $\lim_{x\to+\infty} \left(1 + \dfrac{2}{x}\right)^{x}$ [*Hint:* $t = x/2$]

**63.** Let $f(x) = b^x$, where $0 < b$. Use the substitution principle to verify the asymptotic behavior of $f$ that is illustrated in Figure 0.5.1. [*Hint:* $f(x) = b^x = (e^{\ln b})^x = e^{(\ln b)x}$]

**64.** Prove that $\lim_{x\to0}(1 + x)^{1/x} = e$ by completing parts (a) and (b).

(a) Use Equation (7) and the substitution $t = 1/x$ to prove that $\lim_{x\to0^+}(1 + x)^{1/x} = e$.

(b) Use Equation (8) and the substitution $t = 1/x$ to prove that $\lim_{x\to0^-}(1 + x)^{1/x} = e$.

**65.** Suppose that the speed $v$ (in ft/s) of a skydiver $t$ seconds after leaping from a plane is given by the equation $v = 190(1 - e^{-0.168t})$.

(a) Graph $v$ versus $t$.

(b) By evaluating an appropriate limit, show that the graph of $v$ versus $t$ has a horizontal asymptote $v = c$ for an appropriate constant $c$.

(c) What is the physical significance of the constant $c$ in part (b)?

**66.** The population $p$ of the United States (in millions) in year $t$ can be modeled by the function

$$p(t) = \frac{525}{1 + 1.1e^{-0.02225(t-1990)}}$$

(a) Based on this model, what was the U.S. population in 1990?

(b) Plot $p$ versus $t$ for the 200-year period from 1950 to 2150.

(c) By evaluating an appropriate limit, show that the graph of $p$ versus $t$ has a horizontal asymptote $p = c$ for an appropriate constant $c$.

(d) What is the significance of the constant $c$ in part (c) for the population predicted by this model?

**67.** (a) Compute the (approximate) values of the terms in the sequence

$$1.01^{101},\ 1.001^{1001},\ 1.0001^{10001},\ 1.00001^{100001},$$
$$1.000001^{1000001},\ 1.0000001^{10000001}\ \ldots$$

What number do these terms appear to be approaching?

(b) Use Equation (7) to verify your answer in part (a).

(c) Let $1 \le a \le 9$ denote a positive integer. What number is approached more and more closely by the terms in the following sequence?

$$1.01^{a0a},\ 1.001^{a00a},\ 1.0001^{a000a},\ 1.00001^{a0000a},$$
$$1.000001^{a00000a},\ 1.0000001^{a000000a}\ \ldots$$

(The powers are positive integers that begin and end with the digit $a$ and have 0's in the remaining positions).

**68.** Let $f(x) = \left(1 + \dfrac{1}{x}\right)^{x}$.

(a) Prove the identity

$$f(-x) = \frac{x}{x-1} \cdot f(x-1)$$

(b) Use Equation (7) and the identity from part (a) to prove Equation (8).

**69–73** The notion of an asymptote can be extended to include curves as well as lines. Specifically, we say that curves $y = f(x)$ and $y = g(x)$ are ***asymptotic as $x \to +\infty$*** provided

$$\lim_{x\to+\infty} [f(x) - g(x)] = 0$$

and are ***asymptotic as $x \to -\infty$*** provided

$$\lim_{x\to-\infty} [f(x) - g(x)] = 0$$

In these exercises, determine a simpler function $g(x)$ such that $y = f(x)$ is asymptotic to $y = g(x)$ as $x \to +\infty$ or $x \to -\infty$. Use a graphing utility to generate the graphs of $y = f(x)$ and $y = g(x)$ and identify all vertical asymptotes. ■

**69.** $f(x) = \dfrac{x^2 - 2}{x - 2}$ [*Hint:* Divide $x - 2$ into $x^2 - 2$.]

**70.** $f(x) = \dfrac{x^3 - x + 3}{x}$

**71.** $f(x) = \dfrac{-x^3 + 3x^2 + x - 1}{x - 3}$

**72.** $f(x) = \dfrac{x^5 - x^3 + 3}{x^2 - 1}$

**73.** $f(x) = \sin x + \dfrac{1}{x - 1}$

**74. Writing** In some models for learning a skill (e.g., juggling), it is assumed that the skill level for an individual increases with practice but cannot become arbitrarily high. How do concepts of this section apply to such a model?

**75. Writing** In some population models it is assumed that a given ecological system possesses a ***carrying capacity*** $L$. Populations greater than the carrying capacity tend to decline toward $L$, while populations less than the carrying capacity tend to increase toward $L$. Explain why these assumptions are reasonable, and discuss how the concepts of this section apply to such a model.

## ✔ QUICK CHECK ANSWERS 1.3

**1.** (a) $+\infty$ (b) 5 (c) $-\infty$ (d) 0 **2.** (a) $\frac{1}{2}$ (b) does not exist (c) $e$ **3.** (a) 9 (b) $-\frac{2}{3}$ (c) does not exist (d) 4 **4.** $1/x$, $e^x$, and $e^{-x}$ each has a horizontal asymptote.

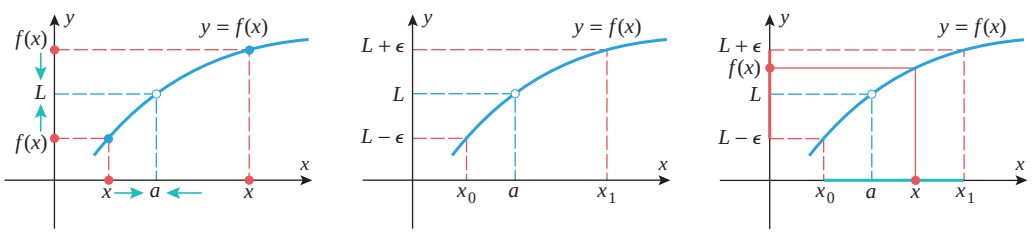
# 1.4 LIMITS (DISCUSSED MORE RIGOROUSLY)

*In the previous sections of this chapter we focused on the discovery of values of limits, either by sampling selected $x$-values or by applying limit theorems that were stated without proof. Our main goal in this section is to define the notion of a limit precisely, thereby making it possible to establish limits with certainty and to prove theorems about them. This will also provide us with a deeper understanding of some of the more subtle properties of functions.*

## MOTIVATION FOR THE DEFINITION OF A TWO-SIDED LIMIT

The statement $\lim_{x \to a} f(x) = L$ can be interpreted informally to mean that we can make the value of $f(x)$ as close as we like to the real number $L$ by making the value of $x$ sufficiently close to $a$. It is our goal to make the informal phrases "as close as we like to $L$" and "sufficiently close to $a$" mathematically precise.

To do this, consider the function $f$ graphed in Figure 1.4.1*a* for which $f(x) \to L$ as $x \to a$. For visual simplicity we have drawn the graph of $f$ to be increasing on an open interval containing $a$, and we have intentionally placed a hole in the graph at $x = a$ to emphasize that $f$ need not be defined at $x = a$ to have a limit there.



▲ **Figure 1.4.1**

Next, let us choose any positive number $\epsilon$ and ask how close $x$ must be to $a$ in order for the values of $f(x)$ to be within $\epsilon$ units of $L$. We can answer this geometrically by drawing horizontal lines from the points $L + \epsilon$ and $L - \epsilon$ on the $y$-axis until they meet the curve $y = f(x)$, and then drawing vertical lines from those points on the curve to the $x$-axis (Figure 1.4.1*b*). As indicated in the figure, let $x_0$ and $x_1$ be the points where those vertical lines intersect the $x$-axis.

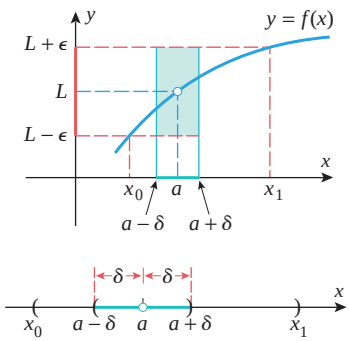
Now imagine that $x$ gets closer and closer to $a$ (from either side). Eventually, $x$ will lie inside the interval $(x_0, x_1)$, which is marked in green in Figure 1.4.1*c*; and when this happens, the value of $f(x)$ will fall between $L - \epsilon$ and $L + \epsilon$, marked in red in the figure. Thus, we conclude:

> *If $f(x) \to L$ as $x \to a$, then for any positive number $\epsilon$, we can find an open interval $(x_0, x_1)$ on the $x$-axis that contains $a$ and has the property that for each $x$ in that interval (except possibly for $x = a$), the value of $f(x)$ is between $L - \epsilon$ and $L + \epsilon$.*

What is important about this result is that it holds no matter how small we make $\epsilon$. However, making $\epsilon$ smaller and smaller forces $f(x)$ *closer and closer* to $L$—which is precisely the concept we were trying to capture mathematically.

Observe that in Figure 1.4.1 the interval $(x_0, x_1)$ extends farther on the right side of $a$ than on the left side. However, for many purposes it is preferable to have an interval that extends the same distance on both sides of $a$. For this purpose, let us choose any positive number $\delta$ that is smaller than both $x_1 - a$ and $a - x_0$, and consider the interval

$$(a - \delta, a + \delta)$$



▲ **Figure 1.4.2**

This interval extends the same distance $\delta$ on both sides of $a$ and lies inside of the interval $(x_0, x_1)$ (Figure 1.4.2). Moreover, the condition

$$L - \epsilon < f(x) < L + \epsilon \tag{1}$$

holds for every $x$ in this interval (except possibly $x = a$), since this condition holds on the larger interval $(x_0, x_1)$.

Since (1) can be expressed as

$$|f(x) - L| < \epsilon$$

and the condition that $x$ lies in the interval $(a - \delta, a + \delta)$, but $x \neq a$, can be expressed as

$$0 < |x - a| < \delta$$

we are led to the following precise definition of a two-sided limit.

The definitions of one-sided limits require minor adjustments to Definition 1.4.1. For example, for a limit from the right we need only assume that $f(x)$ is defined on an interval $(a, b)$ extending to the right of $a$ and that the $\epsilon$ condition is met for $x$ in an interval $a < x < a + \delta$ extending to the right of $a$. A similar adjustment must be made for a limit from the left. (See Exercise 27.)

**1.4.1 LIMIT DEFINITION** Let $f(x)$ be defined for all $x$ in some open interval containing the number $a$, with the possible exception that $f(x)$ need not be defined at $a$. We will write

$$\lim_{x \to a} f(x) = L$$

if given any number $\epsilon > 0$ we can find a number $\delta > 0$ such that

$$|f(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta$$

This definition, which is attributed to the German mathematician Karl Weierstrass and is commonly called the "epsilon-delta" definition of a two-sided limit, makes the transition from an informal concept of a limit to a precise definition. Specifically, the informal phrase "as close as we like to $L$" is given quantitative meaning by our ability to choose the positive number $\epsilon$ arbitrarily, and the phrase "sufficiently close to $a$" is quantified by the positive number $\delta$.

In the preceding sections we illustrated various numerical and graphical methods for *guessing* at limits. Now that we have a precise definition to work with, we can actually

confirm the validity of those guesses with mathematical proof. Here is a typical example of such a proof.

**▶ Example 1** Use Definition 1.4.1 to prove that $\lim_{x \to 2} (3x - 5) = 1$.

***Solution.*** We must show that given any positive number $\epsilon$, we can find a positive number $\delta$ such that

$$|\underbrace{(3x - 5)}_{f(x)} - \underbrace{1}_{L}| < \epsilon \quad \text{if} \quad 0 < |x - \underbrace{2}_{a}| < \delta \tag{2}$$

There are two things to do. First, we must *discover* a value of $\delta$ for which this statement holds, and then we must *prove* that the statement holds for that $\delta$. For the discovery part we begin by simplifying (2) and writing it as

$$|3x - 6| < \epsilon \quad \text{if} \quad 0 < |x - 2| < \delta$$

Next we will rewrite this statement in a form that will facilitate the discovery of an appropriate $\delta$:

$$\begin{aligned} 3|x - 2| &< \epsilon \quad \text{if} \quad 0 < |x - 2| < \delta \\ |x - 2| &< \epsilon/3 \quad \text{if} \quad 0 < |x - 2| < \delta \end{aligned} \tag{3}$$

It should be self-evident that this last statement holds if $\delta = \epsilon/3$, which completes the discovery portion of our work. Now we need to prove that (2) holds for this choice of $\delta$. However, statement (2) is equivalent to (3), and (3) holds with $\delta = \epsilon/3$, so (2) also holds with $\delta = \epsilon/3$. This proves that $\lim_{x \to 2} (3x - 5) = 1$. ◀

This example illustrates the general form of a limit proof: We *assume* that we are given a positive number $\epsilon$, and we try to *prove* that we can find a positive number $\delta$ such that

$$|f(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta \tag{4}$$

This is done by first discovering $\delta$, and then proving that the discovered $\delta$ works. Since the argument has to be general enough to work for all positive values of $\epsilon$, the quantity $\delta$ has to be expressed as a function of $\epsilon$. In Example 1 we found the function $\delta = \epsilon/3$ by some simple algebra; however, most limit proofs require a little more algebraic and logical ingenuity. Thus, if you find our ensuing discussion of "$\epsilon$-$\delta$" proofs challenging, do not become discouraged; the concepts and techniques are intrinsically difficult. In fact, a precise understanding of limits evaded the finest mathematical minds for more than 150 years after the basic concepts of calculus were discovered.

**Karl Weierstrass (1815–1897)** Weierstrass, the son of a customs officer, was born in Ostenfelde, Germany. As a youth Weierstrass showed outstanding skills in languages and mathematics. However, at the urging of his dominant father, Weierstrass entered the law and commerce program at the University of Bonn. To the chagrin of his family, the rugged and congenial young man concentrated instead on fencing and beer drinking. Four years later he returned home without a degree. In 1839 Weierstrass entered the Academy of Münster to study for a career in secondary education, and he met and studied under an excellent mathematician named Christof Gudermann. Gudermann's ideas greatly influenced the work of Weierstrass. After receiving his teaching certificate, Weierstrass spent the next 15 years in secondary education teaching German, geography, and mathematics. In addition, he taught handwriting to small children. During this period much of Weierstrass's mathematical work was ignored because he was a secondary schoolteacher and not a college professor. Then, in 1854, he published a paper of major importance that created a sensation in the mathematics world and catapulted him to international fame overnight. He was immediately given an honorary Doctorate at the University of Königsberg and began a new career in college teaching at the University of Berlin in 1856. In 1859 the strain of his mathematical research caused a temporary nervous breakdown and led to spells of dizziness that plagued him for the rest of his life. Weierstrass was a brilliant teacher and his classes overflowed with multitudes of auditors. In spite of his fame, he never lost his early beer-drinking congeniality and was always in the company of students, both ordinary and brilliant. Weierstrass was acknowledged as the leading mathematical analyst in the world. He and his students opened the door to the modern school of mathematical analysis.

[*Image: http://commons.wikimedia.org/wiki/File:Karl_Weierstrass.jpg*]

▶ **Example 2** Prove that $\lim_{x \to 0^+} \sqrt{x} = 0$.

***Solution.*** Note that the domain of $\sqrt{x}$ is $0 \le x$, so it is valid to discuss the limit as $x \to 0^+$. We must show that given $\epsilon > 0$, there exists a $\delta > 0$ such that

$$|\sqrt{x} - 0| < \epsilon \quad \text{if} \quad 0 < x - 0 < \delta$$

or more simply,

$$\sqrt{x} < \epsilon \quad \text{if} \quad 0 < x < \delta \tag{5}$$

In Example 2 the limit from the left and the two-sided limit do not exist at $x = 0$ because $\sqrt{x}$ is defined only for nonnegative values of $x$.

But, by squaring both sides of the inequality $\sqrt{x} < \epsilon$, we can rewrite (5) as

$$x < \epsilon^2 \quad \text{if} \quad 0 < x < \delta \tag{6}$$

It should be self-evident that (6) is true if $\delta = \epsilon^2$; and since (6) is a reformulation of (5), we have shown that (5) holds with $\delta = \epsilon^2$. This proves that $\lim_{x \to 0^+} \sqrt{x} = 0$. ◀

## THE VALUE OF $\delta$ IS NOT UNIQUE

In preparation for our next example, we note that the value of $\delta$ in Definition 1.4.1 is not unique; once we have found a value of $\delta$ that fulfills the requirements of the definition, then any *smaller* positive number $\delta_1$ will also fulfill those requirements. That is, if it is true that

$$|f(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta$$

then it will also be true that

$$|f(x) - L| < \epsilon \quad \text{if} \quad 0 < |x - a| < \delta_1$$

▲ **Figure 1.4.3**

This is because $\{x : 0 < |x - a| < \delta_1\}$ is a subset of $\{x : 0 < |x - a| < \delta\}$ (Figure 1.4.3), and hence if $|f(x) - L| < \epsilon$ is satisfied for all $x$ in the larger set, then it will automatically be satisfied for all $x$ in the subset. Thus, in Example 1, where we used $\delta = \epsilon/3$, we could have used any smaller value of $\delta$ such as $\delta = \epsilon/4$, $\delta = \epsilon/5$, or $\delta = \epsilon/6$.

▶ **Example 3** Prove that $\lim_{x \to 3} x^2 = 9$.

***Solution.*** We must show that given any positive number $\epsilon$, we can find a positive number $\delta$ such that

$$|x^2 - 9| < \epsilon \quad \text{if} \quad 0 < |x - 3| < \delta \tag{7}$$

Because $|x - 3|$ occurs on the right side of this "if statement," it will be helpful to factor the left side to introduce a factor of $|x - 3|$. This yields the following alternative form of (7):

$$|x + 3||x - 3| < \epsilon \quad \text{if} \quad 0 < |x - 3| < \delta \tag{8}$$

If you are wondering how we knew to make the restriction $\delta \le 1$, as opposed to $\delta \le 5$ or $\delta \le \frac{1}{2}$, for example, the answer is that 1 is merely a convenient choice—any restriction of the form $\delta \le c$ would work equally well.

We wish to bound the factor $|x + 3|$. If we knew, for example, that $\delta \le 1$, then we would have $-1 < x - 3 < 1$, so $5 < x + 3 < 7$, and consequently $|x + 3| < 7$. Thus, if $\delta \le 1$ and $0 < |x - 3| < \delta$, then

$$|x + 3||x - 3| < 7\delta$$

It follows that (8) will be satisfied for any positive $\delta$ such that $\delta \le 1$ and $7\delta < \epsilon$. We can achieve this by taking $\delta$ to be the minimum of the numbers 1 and $\epsilon/7$, which is sometimes written as $\delta = \min(1, \epsilon/7)$. This proves that $\lim_{x \to 3} x^2 = 9$. ◀

## LIMITS AS $x \to \pm\infty$

In Section 1.3 we discussed the limits

$$\lim_{x \to +\infty} f(x) = L \quad \text{and} \quad \lim_{x \to -\infty} f(x) = L$$

from an intuitive point of view. The first limit can be interpreted to mean that we can make the value of $f(x)$ as close as we like to $L$ by taking $x$ sufficiently large, and the second can be interpreted to mean that we can make the value of $f(x)$ as close as we like to $L$ by taking $x$ sufficiently far to the left of 0. These ideas are captured in the following definitions and are illustrated in Figure 1.4.4.

**1.4.2 DEFINITION** Let $f(x)$ be defined for all $x$ in some infinite open interval extending in the positive $x$-direction. We will write

$$\lim_{x \to +\infty} f(x) = L$$

if given any number $\epsilon > 0$, there corresponds a positive number $N$ such that

$$|f(x) - L| < \epsilon \quad \text{if} \quad x > N$$

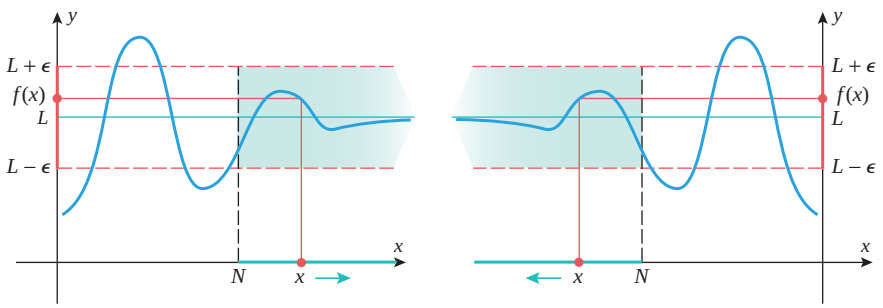
**1.4.3 DEFINITION** Let $f(x)$ be defined for all $x$ in some infinite open interval extending in the negative $x$-direction. We will write

$$\lim_{x \to -\infty} f(x) = L$$

if given any number $\epsilon > 0$, there corresponds a negative number $N$ such that

$$|f(x) - L| < \epsilon \quad \text{if} \quad x < N$$

To see how these definitions relate to our informal concepts of these limits, suppose that $f(x) \to L$ as $x \to +\infty$, and for a given $\epsilon$ let $N$ be the positive number described in Definition 1.4.2. If $x$ is allowed to increase indefinitely, then eventually $x$ will lie in the interval $(N, +\infty)$, which is marked in green in Figure 1.4.4*a*; when this happens, the value of $f(x)$ will fall between $L - \epsilon$ and $L + \epsilon$, marked in red in the figure. Since this is true for all positive values of $\epsilon$ (no matter how small), we can force the values of $f(x)$ as close as we like to $L$ by making $N$ sufficiently large. This agrees with our informal concept of this limit. Similarly, Figure 1.4.4*b* illustrates Definition 1.4.3.



▲ **Figure 1.4.4**

► **Example 4** Prove that $\lim_{x \to +\infty} \frac{1}{x} = 0$.

***Solution.*** Applying Definition 1.4.2 with $f(x) = 1/x$ and $L = 0$, we must show that given $\epsilon > 0$, we can find a number $N > 0$ such that

$$\left|\frac{1}{x} - 0\right| < \epsilon \quad \text{if} \quad x > N \tag{9}$$

Because $x \to +\infty$ we can assume that $x > 0$. Thus, we can eliminate the absolute values in this statement and rewrite it as

$$\frac{1}{x} < \epsilon \quad \text{if} \quad x > N$$

or, on taking reciprocals,

$$x > \frac{1}{\epsilon} \quad \text{if} \quad x > N \tag{10}$$

It is self-evident that $N = 1/\epsilon$ satisfies this requirement, and since (10) and (9) are equivalent for $x > 0$, the proof is complete. ◀

## INFINITE LIMITS

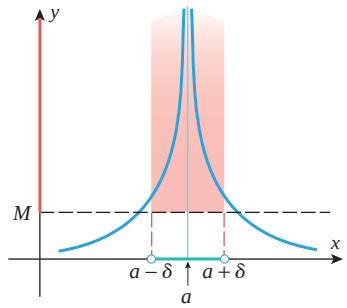
In Section 1.1 we discussed limits of the following type from an intuitive viewpoint:

$$\lim_{x \to a} f(x) = +\infty, \qquad \lim_{x \to a} f(x) = -\infty \tag{11}$$

$$\lim_{x \to a^+} f(x) = +\infty, \qquad \lim_{x \to a^+} f(x) = -\infty \tag{12}$$

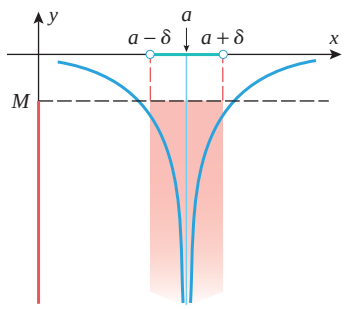
$$\lim_{x \to a^-} f(x) = +\infty, \qquad \lim_{x \to a^-} f(x) = -\infty \tag{13}$$

Recall that each of these expressions describes a particular way in which the limit fails to exist. The $+\infty$ indicates that the limit fails to exist because $f(x)$ increases without bound, and the $-\infty$ indicates that the limit fails to exist because $f(x)$ decreases without bound. These ideas are captured more precisely in the following definitions and are illustrated in Figure 1.4.5.



$f(x) > M$ if $0 < |x - a| < \delta$

(a)



$f(x) < M$ if $0 < |x - a| < \delta$

(b)

▲ **Figure 1.4.5**

**1.4.4 DEFINITION** Let $f(x)$ be defined for all $x$ in some open interval containing $a$, except that $f(x)$ need not be defined at $a$. We will write

$$\lim_{x \to a} f(x) = +\infty$$

if given any positive number $M$, we can find a number $\delta > 0$ such that $f(x)$ satisfies

$$f(x) > M \quad \text{if} \quad 0 < |x - a| < \delta$$

**1.4.5 DEFINITION** Let $f(x)$ be defined for all $x$ in some open interval containing $a$, except that $f(x)$ need not be defined at $a$. We will write

$$\lim_{x \to a} f(x) = -\infty$$

if given any negative number $M$, we can find a number $\delta > 0$ such that $f(x)$ satisfies

$$f(x) < M \quad \text{if} \quad 0 < |x - a| < \delta$$

How would you define these limits?

$$\lim_{x \to a^+} f(x) = +\infty \qquad \lim_{x \to a^+} f(x) = -\infty$$
$$\lim_{x \to a^-} f(x) = +\infty \qquad \lim_{x \to a^-} f(x) = -\infty$$
$$\lim_{x \to +\infty} f(x) = +\infty \qquad \lim_{x \to +\infty} f(x) = -\infty$$
$$\lim_{x \to -\infty} f(x) = +\infty \qquad \lim_{x \to -\infty} f(x) = -\infty$$

To see how these definitions relate to our informal concepts of these limits, suppose that $f(x) \to +\infty$ as $x \to a$, and for a given $M$ let $\delta$ be the corresponding positive number described in Definition 1.4.4. Next, imagine that $x$ gets closer and closer to $a$ (from either side). Eventually, $x$ will lie in the interval $(a - \delta, a + \delta)$, which is marked in green in Figure 1.4.5*a*; when this happens the value of $f(x)$ will be greater than $M$, marked in red in

the figure. Since this is true for any positive value of $M$ (no matter how large), we can force the values of $f(x)$ to be as large as we like by making $x$ sufficiently close to $a$. This agrees with our informal concept of this limit. Similarly, Figure 1.4.5*b* illustrates Definition 1.4.5.

**▶ Example 5** Prove that $\lim_{x\to 0} \dfrac{1}{x^2} = +\infty$.

***Solution.*** Applying Definition 1.4.4 with $f(x) = 1/x^2$ and $a = 0$, we must show that given a number $M > 0$, we can find a number $\delta > 0$ such that

$$\frac{1}{x^2} > M \quad \text{if} \quad 0 < |x - 0| < \delta \tag{14}$$

or, on taking reciprocals and simplifying,

$$x^2 < \frac{1}{M} \quad \text{if} \quad 0 < |x| < \delta \tag{15}$$

But $x^2 < 1/M$ if $|x| < 1/\sqrt{M}$, so that $\delta = 1/\sqrt{M}$ satisfies (15). Since (14) is equivalent to (15), the proof is complete. ◀

## ✔ QUICK CHECK EXERCISES 1.4 (See page 109 for answers.)

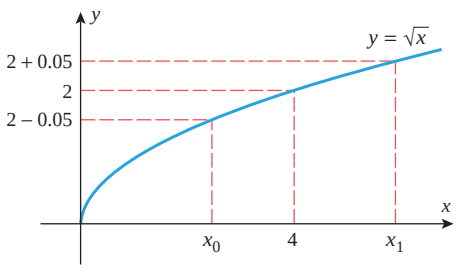
1. The definition of a two-sided limit states: $\lim_{x\to a} f(x) = L$ if given any number _____ there is a number _____ such that $|f(x) - L| < \epsilon$ if _____.
2. Suppose that $f(x)$ is a function such that for any given $\epsilon > 0$, the condition $0 < |x - 1| < \epsilon/2$ guarantees that $|f(x) - 5| < \epsilon$. What limit results from this property?
3. Suppose that $\epsilon$ is any positive number. Find the largest value of $\delta$ such that $|5x - 10| < \epsilon$ if $0 < |x - 2| < \delta$.
4. The definition of limit at $+\infty$ states: $\lim_{x\to+\infty} f(x) = L$ if given any number _____ there is a positive number _____ such that $|f(x) - L| < \epsilon$ if _____.
5. Find the smallest positive number $N$ such that for each $x > N$, the value of $f(x) = 1/\sqrt{x}$ is within 0.01 of 0.

## EXERCISE SET 1.4 Graphing Utility

1. (a) Find the largest open interval, centered at the origin on the $x$-axis, such that for each $x$ in the interval the value of the function $f(x) = x + 2$ is within 0.1 unit of the number $f(0) = 2$.
   (b) Find the largest open interval, centered at $x = 3$, such that for each $x$ in the interval the value of the function $f(x) = 4x - 5$ is within 0.01 unit of the number $f(3) = 7$.
   (c) Find the largest open interval, centered at $x = 4$, such that for each $x$ in the interval the value of the function $f(x) = x^2$ is within 0.001 unit of the number $f(4) = 16$.

2. In each part, find the largest open interval, centered at $x = 0$, such that for each $x$ in the interval the value of $f(x) = 2x + 3$ is within $\epsilon$ units of the number $f(0) = 3$.
   (a) $\epsilon = 0.1$ (b) $\epsilon = 0.01$
   (c) $\epsilon = 0.0012$

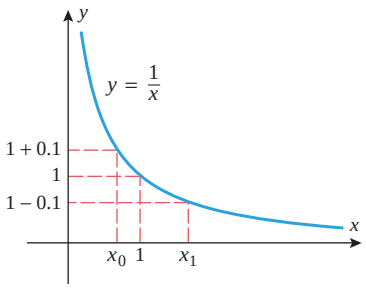
3. (a) Find the values of $x_0$ and $x_1$ in the accompanying figure.
   (b) Find a positive number $\delta$ such that $|\sqrt{x} - 2| < 0.05$ if $0 < |x - 4| < \delta$.



*Not drawn to scale*

▲ **Figure Ex-3**

4. (a) Find the values of $x_0$ and $x_1$ in the accompanying figure on the next page.
   (b) Find a positive number $\delta$ such that $|(1/x) - 1| < 0.1$ if $0 < |x - 1| < \delta$.



*Not drawn to scale* ◀ **Figure Ex-4**

**5.** Generate the graph of $f(x) = x^3 - 4x + 5$ with a graphing utility, and use the graph to find a number $\delta$ such that $|f(x) - 2| < 0.05$ if $0 < |x - 1| < \delta$. [*Hint:* Show that the inequality $|f(x) - 2| < 0.05$ can be rewritten as $1.95 < x^3 - 4x + 5 < 2.05$, and estimate the values of $x$ for which $x^3 - 4x + 5 = 1.95$ and $x^3 - 4x + 5 = 2.05$.]

**6.** Use the method of Exercise 5 to find a number $\delta$ such that $|\sqrt{5x+1} - 4| < 0.5$ if $0 < |x - 3| < \delta$.

**7.** Let $f(x) = x + \sqrt{x}$ with $L = \lim_{x\to 1} f(x)$ and let $\epsilon = 0.2$. Use a graphing utility and its trace feature to find a positive number $\delta$ such that $|f(x) - L| < \epsilon$ if $0 < |x - 1| < \delta$.

**8.** Let $f(x) = (\sin 2x)/x$ and use a graphing utility to conjecture the value of $L = \lim_{x\to 0} f(x)$. Then let $\epsilon = 0.1$ and use the graphing utility and its trace feature to find a positive number $\delta$ such that $|f(x) - L| < \epsilon$ if $0 < |x| < \delta$.

**9–16** A positive number $\epsilon$ and the limit $L$ of a function $f$ at $a$ are given. Find a number $\delta$ such that $|f(x) - L| < \epsilon$ if $0 < |x - a| < \delta$. ■

**9.** $\lim_{x\to 4} 2x = 8;\ \epsilon = 0.1$

**10.** $\lim_{x\to 3} (5x - 2) = 13;\ \epsilon = 0.01$

**11.** $\lim_{x\to 3} \dfrac{x^2 - 9}{x - 3} = 6;\ \epsilon = 0.05$

**12.** $\lim_{x\to -1/2} \dfrac{4x^2 - 1}{2x + 1} = -2;\ \epsilon = 0.05$

**13.** $\lim_{x\to 2} x^3 = 8;\ \epsilon = 0.001$

**14.** $\lim_{x\to 4} \sqrt{x} = 2;\ \epsilon = 0.001$

**15.** $\lim_{x\to 5} \dfrac{1}{x} = \dfrac{1}{5};\ \epsilon = 0.05$

**16.** $\lim_{x\to 0} |x| = 0;\ \epsilon = 0.05$

**17–26** Use Definition 1.4.1 to prove that the limit is correct. ■

**17.** $\lim_{x\to 2} 3 = 3$

**18.** $\lim_{x\to 4} (x + 2) = 6$

**19.** $\lim_{x\to 5} 3x = 15$

**20.** $\lim_{x\to -1} (7x + 5) = -2$

**21.** $\lim_{x\to 0} \dfrac{2x^2 + x}{x} = 1$

**22.** $\lim_{x\to -3} \dfrac{x^2 - 9}{x + 3} = -6$

**23.** $\lim_{x\to 1} f(x) = 3$, where $f(x) = \begin{cases} x + 2, & x \neq 1 \\ 10, & x = 1 \end{cases}$

**24.** $\lim_{x\to 2} f(x) = 5$, where $f(x) = \begin{cases} 9 - 2x, & x \neq 2 \\ 49, & x = 2 \end{cases}$

**25.** $\lim_{x\to 0} |x| = 0$

**26.** $\lim_{x\to 2} f(x) = 5$, where $f(x) = \begin{cases} 9 - 2x, & x < 2 \\ 3x - 1, & x > 2 \end{cases}$

**FOCUS ON CONCEPTS**

**27.** Give rigorous definitions of $\lim_{x\to a^+} f(x) = L$ and $\lim_{x\to a^-} f(x) = L$.

**28.** Consider the statement that $\lim_{x\to a} |f(x) - L| = 0$.

(a) Using Definition 1.4.1, write down precisely what this limit statement means.

(b) Explain why your answer to part (a) shows that

$$\lim_{x\to a} |f(x) - L| = 0 \quad \text{if and only if} \quad \lim_{x\to a} f(x) = L$$

**29.** (a) Show that

$$|(3x^2 + 2x - 20) - 300| = |3x + 32| \cdot |x - 10|$$

(b) Find an upper bound for $|3x + 32|$ if $x$ satisfies $|x - 10| < 1$.

(c) Fill in the blanks to complete a proof that

$$\lim_{x\to 10} [3x^2 + 2x - 20] = 300$$

Suppose that $\epsilon > 0$. Set $\delta = \min(1, _____)$ and assume that $0 < |x - 10| < \delta$. Then

$$\begin{aligned} |(3x^2 + 2x - 20) - 300| &= |3x + 32| \cdot |x - 10| \\ &< _____ \cdot |x - 10| \\ &< _____ \cdot _____ \\ &= \epsilon \end{aligned}$$

**30.** (a) Show that

$$\left| \frac{28}{3x + 1} - 4 \right| = \left| \frac{12}{3x + 1} \right| \cdot |x - 2|$$

(b) Is $|12/(3x + 1)|$ bounded if $|x - 2| < 4$? If not, explain; if so, give a bound.

(c) Is $|12/(3x + 1)|$ bounded if $|x - 2| < 1$? If not, explain; if so, give a bound.

(d) Fill in the blanks to complete a proof that

$$\lim_{x\to 2} \left[ \frac{28}{3x + 1} \right] = 4$$

Suppose that $\epsilon > 0$. Set $\delta = \min(1, _____)$ and assume that $0 < |x - 2| < \delta$. Then

$$\begin{aligned} \left| \frac{28}{3x + 1} - 4 \right| &= \left| \frac{12}{3x + 1} \right| \cdot |x - 2| \\ &< _____ \cdot |x - 2| \\ &< _____ \cdot _____ \\ &= \epsilon \end{aligned}$$

**31–36** Use Definition 1.4.1 to prove that the stated limit is correct. In each case, to show that $\lim_{x\to a} f(x) = L$, factor $|f(x) - L|$ in the form

$$|f(x) - L| = |\text{“something”}| \cdot |x - a|$$

and then bound the size of |“something”| by putting restrictions on the size of $\delta$. ■

**31.** $\lim_{x\to 1} 2x^2 = 2$ [*Hint:* Assume $\delta \le 1$.]

# 1.5 CONTINUITY

*A thrown baseball cannot vanish at some point and reappear someplace else to continue its motion. Thus, we perceive the path of the ball as an unbroken curve. In this section, we translate "unbroken curve" into a precise mathematical formulation called continuity, and develop some fundamental properties of continuous curves.*

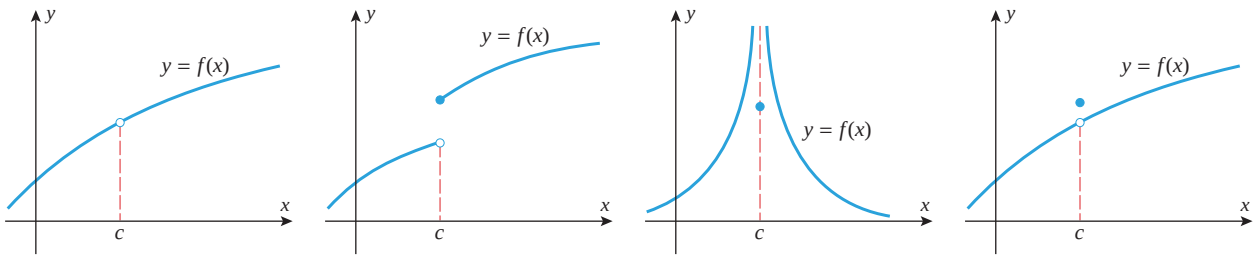
Joseph Helfenberger/iStockphoto

*A baseball moves along a "continuous" trajectory after leaving the pitcher's hand.*

## DEFINITION OF CONTINUITY

Intuitively, the graph of a function can be described as a "continuous curve" if it has no breaks or holes. To make this idea more precise we need to understand what properties of a function can cause breaks or holes. Referring to Figure 1.5.1, we see that the graph of a function has a break or hole if any of the following conditions occur:

- The function $f$ is undefined at $c$ (Figure 1.5.1$a$).
- The limit of $f(x)$ does not exist as $x$ approaches $c$ (Figures 1.5.1$b$, 1.5.1$c$).
- The value of the function and the value of the limit at $c$ are different (Figure 1.5.1$d$).



▲ **Figure 1.5.1**

This suggests the following definition.

**1.5.1 DEFINITION** A function $f$ is said to be ***continuous at $x = c$*** provided the following conditions are satisfied:

1. $f(c)$ is defined.
2. $\lim_{x \to c} f(x)$ exists.
3. $\lim_{x \to c} f(x) = f(c)$.

The third condition in Definition 1.5.1 actually implies the first two, since it is tacitly understood in the statement

$$\lim_{x \to c} f(x) = f(c)$$

that the limit exists and the function is defined at $c$. Thus, when we want to establish continuity at $c$ our usual procedure will be to verify the third condition only.

If one or more of the conditions of this definition fails to hold, then we will say that $f$ has a ***discontinuity at $x = c$***. Each function drawn in Figure 1.5.1 illustrates a discontinuity at $x = c$. In Figure 1.5.1$a$, the function is not defined at $c$, violating the first condition of Definition 1.5.1. In Figure 1.5.1$b$, the one-sided limits of $f(x)$ as $x$ approaches $c$ both exist but are not equal. Thus, $\lim_{x \to c} f(x)$ does not exist, and this violates the second condition of Definition 1.5.1. We will say that a function like that in Figure 1.5.1$b$ has a ***jump discontinuity*** at $c$. In Figure 1.5.1$c$, the one-sided limits of $f(x)$ as $x$ approaches $c$ are infinite. Thus, $\lim_{x \to c} f(x)$ does not exist, and this violates the second condition of Definition 1.5.1. We will say that a function like that in Figure 1.5.1$c$ has an ***infinite discontinuity*** at $c$. In Figure 1.5.1$d$, the function is defined at $c$ and $\lim_{x \to c} f(x)$ exists, but these two values are not equal, violating the third condition of Definition 1.5.1. We will

say that a function like that in Figure 1.5.1*d* has a ***removable discontinuity*** at $c$. Exercises 33 and 34 help to explain why discontinuities of this type are given this name.

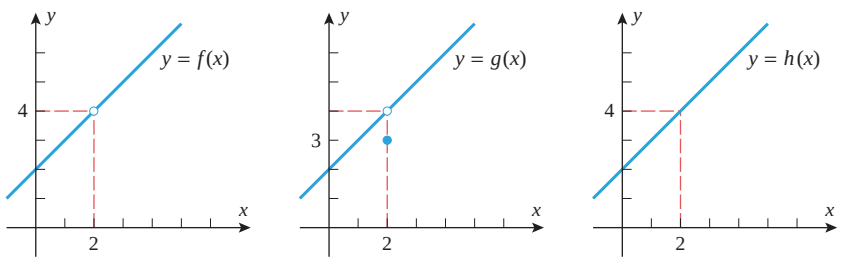
**▶ Example 1** Determine whether the following functions are continuous at $x = 2$.

$$f(x) = \frac{x^2 - 4}{x - 2}, \qquad g(x) = \begin{cases} \dfrac{x^2 - 4}{x - 2}, & x \neq 2 \\ 3, & x = 2, \end{cases} \qquad h(x) = \begin{cases} \dfrac{x^2 - 4}{x - 2}, & x \neq 2 \\ 4, & x = 2 \end{cases}$$

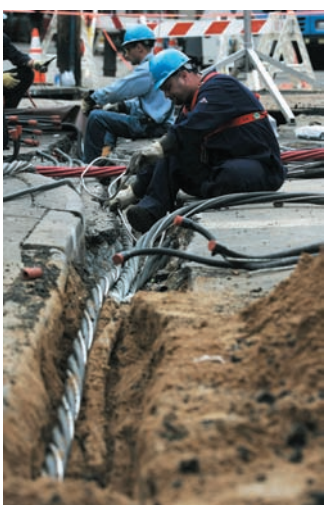
***Solution.*** In each case we must determine whether the limit of the function as $x \to 2$ is the same as the value of the function at $x = 2$. In all three cases the functions are identical, except at $x = 2$, and hence all three have the same limit at $x = 2$, namely,

$$\lim_{x \to 2} f(x) = \lim_{x \to 2} g(x) = \lim_{x \to 2} h(x) = \lim_{x \to 2} \frac{x^2 - 4}{x - 2} = \lim_{x \to 2} (x + 2) = 4$$

The function $f$ is undefined at $x = 2$, and hence is not continuous at $x = 2$ (Figure 1.5.2*a*). The function $g$ is defined at $x = 2$, but its value there is $g(2) = 3$, which is not the same as the limit as $x$ approaches 2; hence, $g$ is also not continuous at $x = 2$ (Figure 1.5.2*b*). The value of the function $h$ at $x = 2$ is $h(2) = 4$, which is the same as the limit as $x$ approaches 2; hence, $h$ is continuous at $x = 2$ (Figure 1.5.2*c*). (Note that the function $h$ could have been written more simply as $h(x) = x + 2$, but we wrote it in piecewise form to emphasize its relationship to $f$ and $g$.) ◀



▲ **Figure 1.5.2**

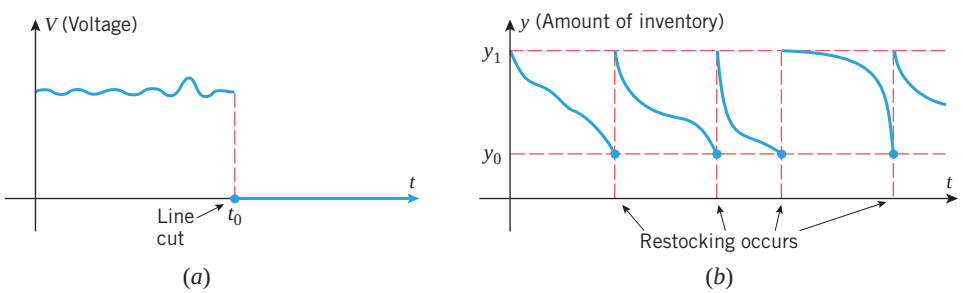


Chris Hondros/Getty Images

*A poor connection in a transmission cable can cause a discontinuity in the electrical signal it carries.*

## CONTINUITY IN APPLICATIONS

In applications, discontinuities often signal the occurrence of important physical events. For example, Figure 1.5.3*a* is a graph of voltage versus time for an underground cable that is accidentally cut by a work crew at time $t = t_0$ (the voltage drops to zero when the line is cut). Figure 1.5.3*b* shows the graph of inventory versus time for a company that restocks its warehouse to $y_1$ units when the inventory falls to $y_0$ units. The discontinuities occur at those times when restocking occurs.



▲ **Figure 1.5.3**

## CONTINUITY ON AN INTERVAL

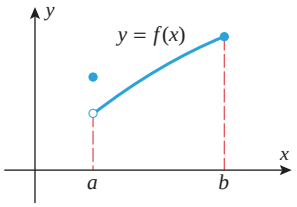
If a function $f$ is continuous at each number in an open interval $(a, b)$, then we say that $f$ is ***continuous on (a, b)***. This definition applies to infinite open intervals of the form $(a, +\infty)$, $(-\infty, b)$, and $(-\infty, +\infty)$. In the case where $f$ is continuous on $(-\infty, +\infty)$, we will say that $f$ is ***continuous everywhere***.

Because Definition 1.5.1 involves a two-sided limit, that definition does not generally apply at the endpoints of a closed interval $[a, b]$ or at the endpoint of an interval of the form $[a, b)$, $(a, b]$, $(-\infty, b]$, or $[a, +\infty)$. To remedy this problem, we will agree that a function is continuous at an endpoint of an interval if its value at the endpoint is equal to the appropriate one-sided limit at that endpoint. For example, the function graphed in Figure 1.5.4 is continuous at the right endpoint of the interval $[a, b]$ because

$$\lim_{x \to b^-} f(x) = f(b)$$

but it is not continuous at the left endpoint because

$$\lim_{x \to a^+} f(x) \neq f(a)$$



▲ Figure 1.5.4

In general, we will say a function $f$ is ***continuous from the left*** at $c$ if

$$\lim_{x \to c^-} f(x) = f(c)$$

and is ***continuous from the right*** at $c$ if

$$\lim_{x \to c^+} f(x) = f(c)$$

Using this terminology we define continuity on a closed interval as follows.

**1.5.2 DEFINITION** A function $f$ is said to be ***continuous on a closed interval [a, b]*** if the following conditions are satisfied:

1. $f$ is continuous on $(a, b)$.
2. $f$ is continuous from the right at $a$.
3. $f$ is continuous from the left at $b$.

Modify Definition 1.5.2 appropriately so that it applies to intervals of the form $[a, +\infty)$, $(-\infty, b]$, $(a, b]$, and $[a, b)$.

▶ **Example 2** What can you say about the continuity of the function $f(x) = \sqrt{9 - x^2}$?

***Solution.*** Because the natural domain of this function is the closed interval $[-3, 3]$, we will need to investigate the continuity of $f$ on the open interval $(-3, 3)$ and at the two endpoints. If $c$ is any point in the interval $(-3, 3)$, then it follows from Theorem 1.2.2(*e*) that

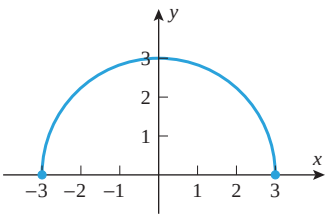
$$\lim_{x \to c} f(x) = \lim_{x \to c} \sqrt{9 - x^2} = \sqrt{\lim_{x \to c} (9 - x^2)} = \sqrt{9 - c^2} = f(c)$$

which proves $f$ is continuous at each point in the interval $(-3, 3)$. The function $f$ is also continuous at the endpoints since

$$\lim_{x \to 3^-} f(x) = \lim_{x \to 3^-} \sqrt{9 - x^2} = \sqrt{\lim_{x \to 3^-} (9 - x^2)} = 0 = f(3)$$

$$\lim_{x \to -3^+} f(x) = \lim_{x \to -3^+} \sqrt{9 - x^2} = \sqrt{\lim_{x \to -3^+} (9 - x^2)} = 0 = f(-3)$$

Thus, $f$ is continuous on the closed interval $[-3, 3]$ (Figure 1.5.5). ◀



▲ Figure 1.5.5

## SOME PROPERTIES OF CONTINUOUS FUNCTIONS

The following theorem, which is a consequence of Theorem 1.2.2, will enable us to reach conclusions about the continuity of functions that are obtained by adding, subtracting, multiplying, and dividing continuous functions.

**1.5.3 THEOREM** *If the functions $f$ and $g$ are continuous at $c$, then*

(*a*) $f + g$ *is continuous at* $c$.

(*b*) $f - g$ *is continuous at* $c$.

(*c*) $fg$ *is continuous at* $c$.

(*d*) $f/g$ *is continuous at* $c$ *if* $g(c) \neq 0$ *and has a discontinuity at* $c$ *if* $g(c) = 0$.

We will prove part (*d*). The remaining proofs are similar and will be left to the exercises.

**PROOF** First, consider the case where $g(c) = 0$. In this case $f(c)/g(c)$ is undefined, so the function $f/g$ has a discontinuity at $c$.

Next, consider the case where $g(c) \neq 0$. To prove that $f/g$ is continuous at $c$, we must show that

$$\lim_{x \to c} \frac{f(x)}{g(x)} = \frac{f(c)}{g(c)} \tag{1}$$

Since $f$ and $g$ are continuous at $c$,

$$\lim_{x \to c} f(x) = f(c) \quad \text{and} \quad \lim_{x \to c} g(x) = g(c)$$

Thus, by Theorem 1.2.2(*d*)

$$\lim_{x \to c} \frac{f(x)}{g(x)} = \frac{\lim\limits_{x \to c} f(x)}{\lim\limits_{x \to c} g(x)} = \frac{f(c)}{g(c)}$$

which proves (1). ■

## CONTINUITY OF POLYNOMIALS AND RATIONAL FUNCTIONS

The general procedure for showing that a function is continuous everywhere is to show that it is continuous at an *arbitrary* point. For example, we know from Theorem 1.2.3 that if $p(x)$ is a polynomial and $a$ is *any* real number, then

$$\lim_{x \to a} p(x) = p(a)$$

This shows that polynomials are continuous everywhere. Moreover, since rational functions are ratios of polynomials, it follows from part (*d*) of Theorem 1.5.3 that rational functions are continuous at points other than the zeros of the denominator, and at these zeros they have discontinuities. Thus, we have the following result.

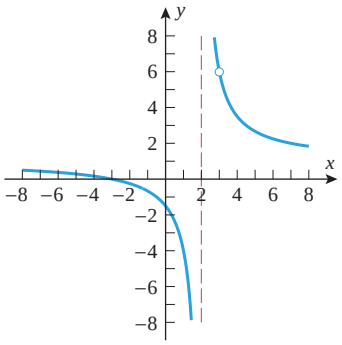
**1.5.4 THEOREM**

(*a*) *A polynomial is continuous everywhere.*

(*b*) *A rational function is continuous at every point where the denominator is nonzero, and has discontinuities at the points where the denominator is zero.*

**TECHNOLOGY MASTERY**

If you use a graphing utility to generate the graph of the equation in Example 3, there is a good chance you will see the discontinuity at $x = 2$ but not at $x = 3$. Try it, and explain what you think is happening.



▲ Figure 1.5.6

**▶ Example 3** For what values of $x$ is there a discontinuity in the graph of

$$y = \frac{x^2 - 9}{x^2 - 5x + 6}?$$

***Solution.*** The function being graphed is a rational function, and hence is continuous at every number where the denominator is nonzero. Solving the equation

$$x^2 - 5x + 6 = 0$$

yields discontinuities at $x = 2$ and at $x = 3$ (Figure 1.5.6). ◀

**▶ Example 4** Show that $|x|$ is continuous everywhere (Figure 0.1.9).

***Solution.*** We can write $|x|$ as

$$|x| = \begin{cases} x & \text{if} \quad x > 0 \\ 0 & \text{if} \quad x = 0 \\ -x & \text{if} \quad x < 0 \end{cases}$$

so $|x|$ is the same as the polynomial $x$ on the interval $(0, +\infty)$ and is the same as the polynomial $-x$ on the interval $(-\infty, 0)$. But polynomials are continuous everywhere, so $x = 0$ is the only possible discontinuity for $|x|$. Since $|0| = 0$, to prove the continuity at $x = 0$ we must show that

$$\lim_{x \to 0} |x| = 0 \tag{2}$$

Because the piecewise formula for $|x|$ changes at 0, it will be helpful to consider the one-sided limits at 0 rather than the two-sided limit. We obtain

$$\lim_{x \to 0^+} |x| = \lim_{x \to 0^+} x = 0 \quad \text{and} \quad \lim_{x \to 0^-} |x| = \lim_{x \to 0^-} (-x) = 0$$

Thus, (2) holds and $|x|$ is continuous at $x = 0$. ◀

## CONTINUITY OF COMPOSITIONS

The following theorem, whose proof is given in Appendix J, will be useful for calculating limits of compositions of functions.

In words, Theorem 1.5.5 states that a limit symbol can be moved through a function sign provided the limit of the expression inside the function sign exists and the function is continuous at this limit.

**1.5.5 THEOREM** *If* $\lim_{x \to c} g(x) = L$ *and if the function* $f$ *is continuous at* $L$, *then* $\lim_{x \to c} f(g(x)) = f(L)$. *That is,*

$$\lim_{x \to c} f(g(x)) = f\left(\lim_{x \to c} g(x)\right)$$

*This equality remains valid if* $\lim_{x \to c}$ *is replaced everywhere by one of* $\lim_{x \to c^+}$, $\lim_{x \to c^-}$, $\lim_{x \to +\infty}$, *or* $\lim_{x \to -\infty}$.

In the special case of this theorem where $f(x) = |x|$, the fact that $|x|$ is continuous everywhere allows us to write

$$\lim_{x \to c} |g(x)| = \left|\lim_{x \to c} g(x)\right| \tag{3}$$

provided $\lim_{x \to c} g(x)$ exists. Thus, for example,

$$\lim_{x \to 3} |5 - x^2| = \left|\lim_{x \to 3} (5 - x^2)\right| = |-4| = 4$$

The following theorem is concerned with the continuity of compositions of functions; the first part deals with continuity at a specific number and the second with continuity everywhere.

**1.5.6 THEOREM**

(*a*) *If the function $g$ is continuous at $c$, and the function $f$ is continuous at $g(c)$, then the composition $f \circ g$ is continuous at $c$.*

(*b*) *If the function $g$ is continuous everywhere and the function $f$ is continuous everywhere, then the composition $f \circ g$ is continuous everywhere.*

**PROOF** We will prove part (*a*) only; the proof of part (*b*) can be obtained by applying part (*a*) at an arbitrary number $c$. To prove that $f \circ g$ is continuous at $c$, we must show that the value of $f \circ g$ and the value of its limit are the same at $x = c$. But this is so, since we can write

$$\lim_{x \to c} (f \circ g)(x) = \lim_{x \to c} f(g(x)) = f\left(\lim_{x \to c} g(x)\right) = f(g(c)) = (f \circ g)(c) \quad \blacksquare$$

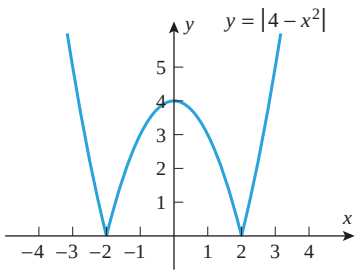
Theorem 1.5.5 — $g$ is continuous at $c$.

Can the absolute value of a function that is not continuous everywhere be continuous everywhere? Justify your answer.

We know from Example 4 that the function $|x|$ is continuous everywhere. Thus, if $g(x)$ is continuous at $c$, then by part (*a*) of Theorem 1.5.6, the function $|g(x)|$ must also be continuous at $c$; and, more generally, if $g(x)$ is continuous everywhere, then so is $|g(x)|$. Stated informally:

*The absolute value of a continuous function is continuous.*

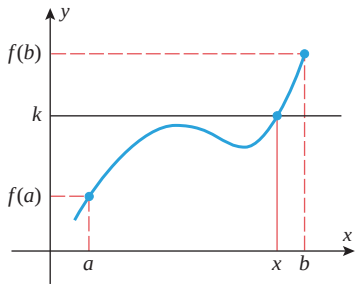
For example, the polynomial $g(x) = 4 - x^2$ is continuous everywhere, so we can conclude that the function $|4 - x^2|$ is also continuous everywhere (Figure 1.5.7).



▲ **Figure 1.5.7**

## THE INTERMEDIATE-VALUE THEOREM

Figure 1.5.8 shows the graph of a function that is continuous on the closed interval $[a, b]$. The figure suggests that if we draw any horizontal line $y = k$, where $k$ is between $f(a)$ and $f(b)$, then that line will cross the curve $y = f(x)$ at least once over the interval $[a, b]$. Stated in numerical terms, if $f$ is continuous on $[a, b]$, then the function $f$ must take on every value $k$ between $f(a)$ and $f(b)$ at least once as $x$ varies from $a$ to $b$. For example, the polynomial $p(x) = x^5 - x + 3$ has a value of 3 at $x = 1$ and a value of 33 at $x = 2$. Thus, it follows from the continuity of $p$ that the equation $x^5 - x + 3 = k$ has at least one solution in the interval $[1, 2]$ for every value of $k$ between 3 and 33. This idea is stated more precisely in the following theorem.



▲ **Figure 1.5.8**

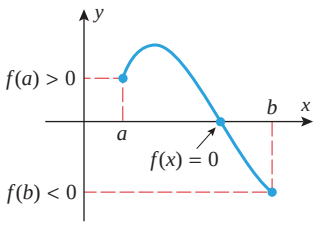
**1.5.7 THEOREM** (***Intermediate-Value Theorem***) *If $f$ is continuous on a closed interval $[a, b]$ and $k$ is any number between $f(a)$ and $f(b)$, inclusive, then there is at least one number $x$ in the interval $[a, b]$ such that $f(x) = k$.*

Although this theorem is intuitively obvious, its proof depends on a mathematically precise development of the real number system, which is beyond the scope of this text.

## APPROXIMATING ROOTS USING THE INTERMEDIATE-VALUE THEOREM

A variety of problems can be reduced to solving an equation $f(x) = 0$ for its roots. Sometimes it is possible to solve for the roots exactly using algebra, but often this is not possible and one must settle for decimal approximations of the roots. One procedure for approximating roots is based on the following consequence of the Intermediate-Value Theorem.

**1.5.8 THEOREM** *If $f$ is continuous on $[a, b]$, and if $f(a)$ and $f(b)$ are nonzero and have opposite signs, then there is at least one solution of the equation $f(x) = 0$ in the interval $(a, b)$.*



▲ Figure 1.5.9

This result, which is illustrated in Figure 1.5.9, can be proved as follows.

**PROOF** Since $f(a)$ and $f(b)$ have opposite signs, 0 is between $f(a)$ and $f(b)$. Thus, by the Intermediate-Value Theorem there is at least one number $x$ in the interval $[a, b]$ such that $f(x) = 0$. However, $f(a)$ and $f(b)$ are nonzero, so $x$ must lie in the interval $(a, b)$, which completes the proof. ■

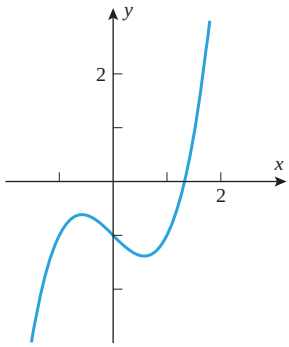
Before we illustrate how this theorem can be used to approximate roots, it will be helpful to discuss some standard terminology for describing errors in approximations. If $x$ is an approximation to a quantity $x_0$, then we call

$$\epsilon = |x - x_0|$$

the ***absolute error*** or (less precisely) the ***error*** in the approximation. The terminology in Table 1.5.1 is used to describe the size of such errors.

**Table 1.5.1**

| ERROR | DESCRIPTION |
|---|---|
| $\|x - x_0\| \le 0.1$ | $x$ approximates $x_0$ with an error of at most 0.1. |
| $\|x - x_0\| \le 0.01$ | $x$ approximates $x_0$ with an error of at most 0.01. |
| $\|x - x_0\| \le 0.001$ | $x$ approximates $x_0$ with an error of at most 0.001. |
| $\|x - x_0\| \le 0.0001$ | $x$ approximates $x_0$ with an error of at most 0.0001. |
| $\|x - x_0\| \le 0.5$ | $x$ approximates $x_0$ to the nearest integer. |
| $\|x - x_0\| \le 0.05$ | $x$ approximates $x_0$ to 1 decimal place (i.e., to the nearest tenth). |
| $\|x - x_0\| \le 0.005$ | $x$ approximates $x_0$ to 2 decimal places (i.e., to the nearest hundredth). |
| $\|x - x_0\| \le 0.0005$ | $x$ approximates $x_0$ to 3 decimal places (i.e., to the nearest thousandth). |



▲ Figure 1.5.10

**► Example 5** The equation

$$x^3 - x - 1 = 0$$

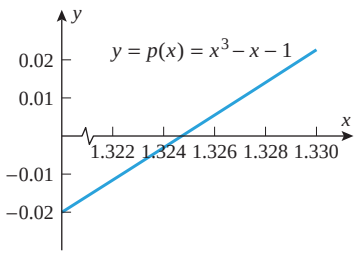
cannot be solved algebraically very easily because the left side has no simple factors. However, if we graph $p(x) = x^3 - x - 1$ with a graphing utility (Figure 1.5.10), then we are led to conjecture that there is one real root and that this root lies inside the interval $[1, 2]$. The existence of a root in this interval is also confirmed by Theorem 1.5.8, since $p(1) = -1$ and $p(2) = 5$ have opposite signs. Approximate this root to two decimal-place accuracy.

***Solution.*** Our objective is to approximate the unknown root $x_0$ with an error of at most 0.005. It follows that if we can find an interval of length 0.01 that contains the root, then the midpoint of that interval will approximate the root with an error of at most $\frac{1}{2}(0.01) = 0.005$, which will achieve the desired accuracy.

We know that the root $x_0$ lies in the interval $[1, 2]$. However, this interval has length 1, which is too large. We can pinpoint the location of the root more precisely by dividing the interval $[1, 2]$ into 10 equal parts and evaluating $p$ at the points of subdivision using a calculating utility (Table 1.5.2). In this table $p(1.3)$ and $p(1.4)$ have opposite signs, so we know that the root lies in the interval $[1.3, 1.4]$. This interval has length 0.1, which is still too large, so we repeat the process by dividing the interval $[1.3, 1.4]$ into 10 parts and evaluating $p$ at the points of subdivision; this yields Table 1.5.3, which tells us that the root is inside the interval $[1.32, 1.33]$ (Figure 1.5.11). Since this interval has length 0.01, its midpoint 1.325 will approximate the root with an error of at most 0.005. Thus, $x_0 \approx 1.325$ to two decimal-place accuracy. ◀

**Table 1.5.2**

| $x$ | 1 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 | 1.6 | 1.7 | 1.8 | 1.9 | 2 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| $p(x)$ | −1 | −0.77 | −0.47 | −0.10 | 0.34 | 0.88 | 1.50 | 2.21 | 3.03 | 3.96 | 5 |



▲ **Figure 1.5.11**

**Table 1.5.3**

| $x$ | 1.3 | 1.31 | 1.32 | 1.33 | 1.34 | 1.35 | 1.36 | 1.37 | 1.38 | 1.39 | 1.4 |
|---|---|---|---|---|---|---|---|---|---|---|---|
| $p(x)$ | −0.103 | −0.062 | −0.020 | 0.023 | 0.066 | 0.110 | 0.155 | 0.201 | 0.248 | 0.296 | 0.344 |

**REMARK**

To say that $x$ approximates $x_0$ to $n$ decimal places does *not* mean that the first $n$ decimal places of $x$ and $x_0$ will be the same when the numbers are rounded to $n$ decimal places. For example, $x = 1.084$ approximates $x_0 = 1.087$ to two decimal places because $|x - x_0| = 0.003\ (< 0.005)$. However, if we round these values to two decimal places, then we obtain $x \approx 1.08$ and $x_0 \approx 1.09$. Thus, if you approximate a number to $n$ decimal places, then you should display that approximation to at least $n + 1$ decimal places to preserve the accuracy.

**TECHNOLOGY MASTERY**

Use a graphing or calculating utility to show that the root $x_0$ in Example 5 can be approximated as $x_0 \approx 1.3245$ to three decimal-place accuracy.

## ✔ QUICK CHECK EXERCISES 1.5 (See page 120 for answers.)

**1.** What three conditions are satisfied if $f$ is continuous at $x = c$?

**2.** Suppose that $f$ and $g$ are continuous functions such that $f(2) = 1$ and $\lim_{x \to 2} [f(x) + 4g(x)] = 13$. Find

(a) $g(2)$

(b) $\lim_{x \to 2} g(x)$.

**3.** Suppose that $f$ and $g$ are continuous functions such that $\lim_{x \to 3} g(x) = 5$ and $f(3) = -2$. Find $\lim_{x \to 3} [f(x)/g(x)]$.

**4.** For what values of $x$, if any, is the function

$$f(x) = \frac{x^2 - 16}{x^2 - 5x + 4}$$

discontinuous?

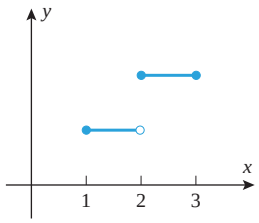
**5.** Suppose that a function $f$ is continuous everywhere and that $f(-2) = 3$, $f(-1) = -1$, $f(0) = -4$, $f(1) = 1$, and $f(2) = 5$. Does the Intermediate-Value Theorem guarantee that $f$ has a root on the following intervals?

(a) $[-2, -1]$ (b) $[-1, 0]$ (c) $[-1, 1]$ (d) $[0, 2]$

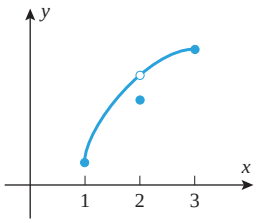
## EXERCISE SET 1.5 Graphing Utility

**1–4** Let $f$ be the function whose graph is shown. On which of the following intervals, if any, is $f$ continuous?
(a) $[1, 3]$ (b) $(1, 3)$ (c) $[1, 2]$
(d) $(1, 2)$ (e) $[2, 3]$ (f) $(2, 3)$
For each interval on which $f$ is not continuous, indicate which conditions for the continuity of $f$ do not hold. ■

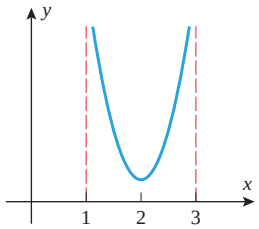
**1.**



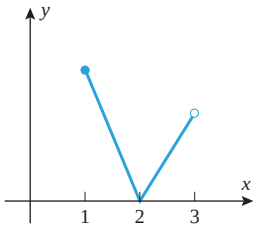
**2.**



**3.**



**4.**



**5.** Consider the functions

$$f(x) = \begin{cases} 1, & x \neq 4 \\ -1, & x = 4 \end{cases} \quad \text{and} \quad g(x) = \begin{cases} 4x - 10, & x \neq 4 \\ -6, & x = 4 \end{cases}$$

In each part, is the given function continuous at $x = 4$?
(a) $f(x)$ (b) $g(x)$ (c) $-g(x)$ (d) $|f(x)|$
(e) $f(x)g(x)$ (f) $g(f(x))$ (g) $g(x) - 6f(x)$

**6.** Consider the functions

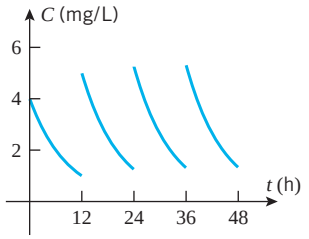
$$f(x) = \begin{cases} 1, & 0 \leq x \\ 0, & x < 0 \end{cases} \quad \text{and} \quad g(x) = \begin{cases} 0, & 0 \leq x \\ 1, & x < 0 \end{cases}$$

In each part, is the given function continuous at $x = 0$?
(a) $f(x)$ (b) $g(x)$ (c) $f(-x)$ (d) $|g(x)|$
(e) $f(x)g(x)$ (f) $g(f(x))$ (g) $f(x) + g(x)$

### FOCUS ON CONCEPTS

**7.** In each part sketch the graph of a function $f$ that satisfies the stated conditions.
(a) $f$ is continuous everywhere except at $x = 3$, at which point it is continuous from the right.
(b) $f$ has a two-sided limit at $x = 3$, but it is not continuous at $x = 3$.
(c) $f$ is not continuous at $x = 3$, but if its value at $x = 3$ is changed from $f(3) = 1$ to $f(3) = 0$, it becomes continuous at $x = 3$.
(d) $f$ is continuous on the interval $[0, 3)$ and is defined on the closed interval $[0, 3]$; but $f$ is not continuous on the interval $[0, 3]$.

**8.** The accompanying figure models the concentration $C$ of medication in the bloodstream of a patient over a 48-hour period of time. Discuss the significance of the discontinuities in the graph.



◀ **Figure Ex-8**

**9.** A student parking lot at a university charges \$2.00 for the first half hour (or any part) and \$1.00 for each subsequent half hour (or any part) up to a daily maximum of \$10.00.
(a) Sketch a graph of cost as a function of the time parked.
(b) Discuss the significance of the discontinuities in the graph to a student who parks there.

**10.** In each part determine whether the function is continuous or not, and explain your reasoning.
(a) The Earth's population as a function of time.
(b) Your exact height as a function of time.
(c) The cost of a taxi ride in your city as a function of the distance traveled.
(d) The volume of a melting ice cube as a function of time.

**11–22** Find values of $x$, if any, at which $f$ is not continuous. ■

**11.** $f(x) = 5x^4 - 3x + 7$

**12.** $f(x) = \sqrt[3]{x - 8}$

**13.** $f(x) = \dfrac{x + 2}{x^2 + 4}$

**14.** $f(x) = \dfrac{x + 2}{x^2 - 4}$

**15.** $f(x) = \dfrac{x}{2x^2 + x}$

**16.** $f(x) = \dfrac{2x + 1}{4x^2 + 4x + 5}$

**17.** $f(x) = \dfrac{3}{x} + \dfrac{x - 1}{x^2 - 1}$

**18.** $f(x) = \dfrac{5}{x} + \dfrac{2x}{x + 4}$

**19.** $f(x) = \dfrac{x^2 + 6x + 9}{|x| + 3}$

**20.** $f(x) = \left| 4 - \dfrac{8}{x^4 + x} \right|$

**21.** $f(x) = \begin{cases} 2x + 3, & x \leq 4 \\ 7 + \dfrac{16}{x}, & x > 4 \end{cases}$

**22.** $f(x) = \begin{cases} \dfrac{3}{x - 1}, & x \neq 1 \\ 3, & x = 1 \end{cases}$

**23–28 True–False** Determine whether the statement is true or false. Explain your answer. ■

**23.** If $f(x)$ is continuous at $x = c$, then so is $|f(x)|$.

**24.** If $|f(x)|$ is continuous at $x = c$, then so is $f(x)$.

**25.** If $f$ and $g$ are discontinuous at $x = c$, then so is $f + g$.

**26.** If $f$ and $g$ are discontinuous at $x = c$, then so is $fg$.

**27.** If $\sqrt{f(x)}$ is continuous at $x = c$, then so is $f(x)$.

**28.** If $f(x)$ is continuous at $x = c$, then so is $\sqrt{f(x)}$.

**29–30** Find a value of the constant $k$, if possible, that will make the function continuous everywhere. ■

**29.** (a) $f(x) = \begin{cases} 7x - 2, & x \le 1 \\ kx^2, & x > 1 \end{cases}$

(b) $f(x) = \begin{cases} kx^2, & x \le 2 \\ 2x + k, & x > 2 \end{cases}$

**30.** (a) $f(x) = \begin{cases} 9 - x^2, & x \ge -3 \\ k/x^2, & x < -3 \end{cases}$

(b) $f(x) = \begin{cases} 9 - x^2, & x \ge 0 \\ k/x^2, & x < 0 \end{cases}$

**31.** Find values of the constants $k$ and $m$, if possible, that will make the function $f$ continuous everywhere.

$$f(x) = \begin{cases} x^2 + 5, & x > 2 \\ m(x + 1) + k, & -1 < x \le 2 \\ 2x^3 + x + 7, & x \le -1 \end{cases}$$

**32.** On which of the following intervals is

$$f(x) = \frac{1}{\sqrt{x - 2}}$$

continuous?

(a) $[2, +\infty)$ (b) $(-\infty, +\infty)$ (c) $(2, +\infty)$ (d) $[1, 2)$

**33–36** A function $f$ is said to have a ***removable discontinuity*** at $x = c$ if $\lim_{x \to c} f(x)$ exists but $f$ is not continuous at $x = c$, either because $f$ is not defined at $c$ or because the definition for $f(c)$ differs from the value of the limit. This terminology will be needed in these exercises. ■

**33.** (a) Sketch the graph of a function with a removable discontinuity at $x = c$ for which $f(c)$ is undefined.

(b) Sketch the graph of a function with a removable discontinuity at $x = c$ for which $f(c)$ is defined.

**34.** (a) The terminology *removable discontinuity* is appropriate because a removable discontinuity of a function $f$ at $x = c$ can be "removed" by redefining the value of $f$ appropriately at $x = c$. What value for $f(c)$ removes the discontinuity?

(b) Show that the following functions have removable discontinuities at $x = 1$, and sketch their graphs.

$$f(x) = \frac{x^2 - 1}{x - 1} \quad \text{and} \quad g(x) = \begin{cases} 1, & x > 1 \\ 0, & x = 1 \\ 1, & x < 1 \end{cases}$$

(c) What values should be assigned to $f(1)$ and $g(1)$ to remove the discontinuities?

**35–36** Find the values of $x$ (if any) at which $f$ is not continuous, and determine whether each such value is a removable discontinuity. ■

**35.** (a) $f(x) = \dfrac{|x|}{x}$ (b) $f(x) = \dfrac{x^2 + 3x}{x + 3}$

(c) $f(x) = \dfrac{x - 2}{|x| - 2}$

**36.** (a) $f(x) = \dfrac{x^2 - 4}{x^3 - 8}$ (b) $f(x) = \begin{cases} 2x - 3, & x \le 2 \\ x^2, & x > 2 \end{cases}$

(c) $f(x) = \begin{cases} 3x^2 + 5, & x \ne 1 \\ 6, & x = 1 \end{cases}$

**37.** (a) Use a graphing utility to generate the graph of the function $f(x) = (x + 3)/(2x^2 + 5x - 3)$, and then use the graph to make a conjecture about the number and locations of all discontinuities.

(b) Check your conjecture by factoring the denominator.

**38.** (a) Use a graphing utility to generate the graph of the function $f(x) = x/(x^3 - x + 2)$, and then use the graph to make a conjecture about the number and locations of all discontinuities.

(b) Use the Intermediate-Value Theorem to approximate the locations of all discontinuities to two decimal places.

**39.** Prove that $f(x) = x^{3/5}$ is continuous everywhere, carefully justifying each step.

**40.** Prove that $f(x) = 1/\sqrt{x^4 + 7x^2 + 1}$ is continuous everywhere, carefully justifying each step.

**41.** Prove:

(a) part $(a)$ of Theorem 1.5.3

(b) part $(b)$ of Theorem 1.5.3

(c) part $(c)$ of Theorem 1.5.3.

**42.** Prove part $(b)$ of Theorem 1.5.4.

**43.** (a) Use Theorem 1.5.5 to prove that if $f$ is continuous at $x = c$, then $\lim_{h \to 0} f(c + h) = f(c)$.

(b) Prove that if $\lim_{h \to 0} f(c + h) = f(c)$, then $f$ is continuous at $x = c$. [*Hint:* What does this limit tell you about the continuity of $g(h) = f(c + h)$?]

(c) Conclude from parts (a) and (b) that $f$ is continuous at $x = c$ if and only if $\lim_{h \to 0} f(c + h) = f(c)$.

**44.** Prove: If $f$ and $g$ are continuous on $[a, b]$, and $f(a) > g(a)$, $f(b) < g(b)$, then there is at least one solution of the equation $f(x) = g(x)$ in $(a, b)$. [*Hint:* Consider $f(x) - g(x)$.]

**FOCUS ON CONCEPTS**

**45.** Give an example of a function $f$ that is defined on a closed interval, and whose values at the endpoints have opposite signs, but for which the equation $f(x) = 0$ has no solution in the interval.

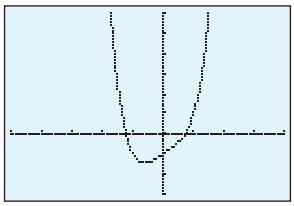
**46.** Let $f$ be the function whose graph is shown in Exercise 2. For each interval, determine (i) whether the hypothesis of the Intermediate-Value Theorem is satisfied, and (ii) whether the conclusion of the Intermediate-Value Theorem is satisfied.

(a) $[1, 2]$ (b) $[2, 3]$ (c) $[1, 3]$

**47.** Show that the equation $x^3 + x^2 - 2x = 1$ has at least one solution in the interval $[-1, 1]$.

**48.** Prove: If $p(x)$ is a polynomial of odd degree, then the equation $p(x) = 0$ has at least one real solution.

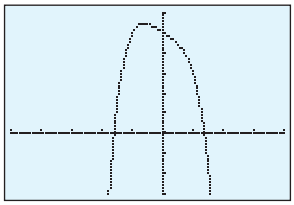
**49.** The accompanying figure shows the graph of the equation $y = x^4 + x - 1$. Use the method of Example 5 to approximate the $x$-intercepts with an error of at most 0.05.



[−5, 4] × [−3, 6]
xScl = 1, yScl = 1

◀ **Figure Ex-49**

**50.** The accompanying figure shows the graph of the equation $y = 5 - x - x^4$. Use the method of Example 5 to approximate the roots of the equation $5 - x - x^4 = 0$ to two decimal-place accuracy.



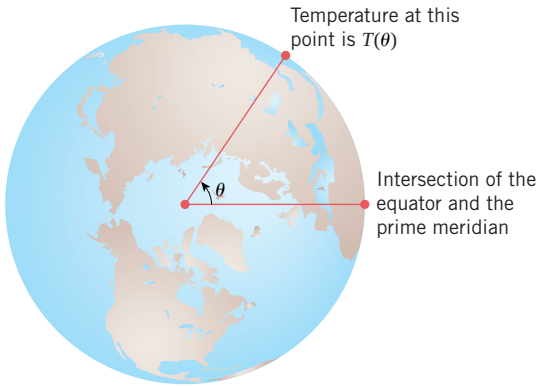
[−5, 4] × [−3, 6]
xScl = 1, yScl = 1

◀ **Figure Ex-50**

**51.** Use the fact that $\sqrt{5}$ is a solution of $x^2 - 5 = 0$ to approximate $\sqrt{5}$ with an error of at most 0.005.

**52.** A sprinter, who is timed with a stopwatch, runs a hundred yard dash in 10 s. The stopwatch is reset to 0, and the sprinter is timed jogging back to the starting block. Show that there is at least one point on the track at which the reading on the stopwatch during the sprint is the same as the reading during the return jog. [*Hint:* Use the result in Exercise 44.]

**53.** Prove that there exist points on opposite sides of the equator that are at the same temperature. [*Hint:* Consider the accompanying figure, which shows a view of the equator from a point above the North Pole. Assume that the temperature $T(\theta)$ is a continuous function of the angle $\theta$, and consider the function $f(\theta) = T(\theta + \pi) - T(\theta)$.]



▲ **Figure Ex-53**

**54.** Let $R$ denote an elliptical region in the $xy$-plane, and define $f(z)$ to be the area within $R$ that is on, or to the left of, the vertical line $x = z$. Prove that $f$ is a continuous function of $z$. [*Hint:* Assume the ellipse is between the horizontal lines $y = a$ and $y = b$, $a < b$. Argue that $|f(z_1) - f(z_2)| \le (b - a) \cdot |z_1 - z_2|$.]

**55.** Let $R$ denote an elliptical region in the plane. For any line $L$, prove there is a line perpendicular to $L$ that divides $R$ in half by area. [*Hint:* Introduce coordinates so that $L$ is the $x$-axis. Use the result in Exercise 54 and the Intermediate-Value Theorem.]

**56.** Suppose that $f$ is continuous on the interval [0, 1] and that $0 \le f(x) \le 1$ for all $x$ in this interval.

(a) Sketch the graph of $y = x$ together with a possible graph for $f$ over the interval [0, 1].

(b) Use the Intermediate-Value Theorem to help prove that there is at least one number $c$ in the interval [0, 1] such that $f(c) = c$.

**57.** **Writing** It is often assumed that changing physical quantities such as the height of a falling object or the weight of a melting snowball, are continuous functions of time. Use specific examples to discuss the merits of this assumption.

**58.** **Writing** The Intermediate-Value Theorem (Theorem 1.5.7) is an example of what is known as an "existence theorem." In your own words, describe how to recognize an existence theorem, and discuss some of the ways in which an existence theorem can be useful.

# 1.6 CONTINUITY OF TRIGONOMETRIC, EXPONENTIAL, AND INVERSE FUNCTIONS

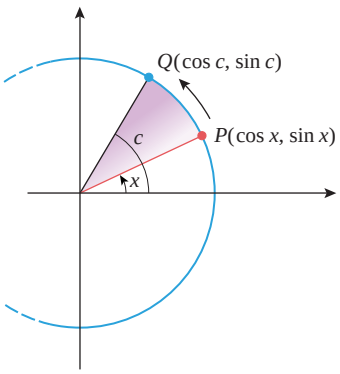
*In this section we will discuss the continuity properties of trigonometric functions, exponential functions, and inverses of various continuous functions. We will also discuss some important limits involving such functions.*

## CONTINUITY OF TRIGONOMETRIC FUNCTIONS

Recall from trigonometry that the graphs of $\sin x$ and $\cos x$ are drawn as continuous curves. We will not formally prove that these functions are continuous, but we can motivate this fact by letting $c$ be a fixed angle in radian measure and $x$ a variable angle in radian measure. If, as illustrated in Figure 1.6.1, the angle $x$ approaches the angle $c$, then the point $P(\cos x, \sin x)$ moves along the unit circle toward $Q(\cos c, \sin c)$, and the coordinates of $P$ approach the corresponding coordinates of $Q$. This implies that

$$\lim_{x \to c} \sin x = \sin c \quad \text{and} \quad \lim_{x \to c} \cos x = \cos c \tag{1}$$

Thus, $\sin x$ and $\cos x$ are continuous at the arbitrary point $c$; that is, these functions are continuous everywhere.



As $x$ approaches $c$ the point $P$ approaches the point $Q$.

▲ **Figure 1.6.1**

The formulas in (1) can be used to find limits of the remaining trigonometric functions by expressing them in terms of $\sin x$ and $\cos x$; for example, if $\cos c \neq 0$, then

$$\lim_{x \to c} \tan x = \lim_{x \to c} \frac{\sin x}{\cos x} = \frac{\sin c}{\cos c} = \tan c$$

Thus, we are led to the following theorem.

Theorem 1.6.1 implies that the six basic trigonometric functions are continuous on their domains. In particular, $\sin x$ and $\cos x$ are continuous everywhere.

**1.6.1 THEOREM** *If $c$ is any number in the natural domain of the stated trigonometric function, then*

$$\lim_{x \to c} \sin x = \sin c \qquad \lim_{x \to c} \cos x = \cos c \qquad \lim_{x \to c} \tan x = \tan c$$
$$\lim_{x \to c} \csc x = \csc c \qquad \lim_{x \to c} \sec x = \sec c \qquad \lim_{x \to c} \cot x = \cot c$$

▶ **Example 1** Find the limit

$$\lim_{x \to 1} \cos\left(\frac{x^2 - 1}{x - 1}\right)$$

***Solution.*** Since the cosine function is continuous everywhere, it follows from Theorem 1.5.5 that

$$\lim_{x \to 1} \cos(g(x)) = \cos\left(\lim_{x \to 1} g(x)\right)$$

provided $\lim_{x \to 1} g(x)$ exists. Thus,

$$\lim_{x \to 1} \cos\left(\frac{x^2 - 1}{x - 1}\right) = \lim_{x \to 1} \cos(x + 1) = \cos\left(\lim_{x \to 1} (x + 1)\right) = \cos 2 \quad \blacktriangleleft$$

## CONTINUITY OF INVERSE FUNCTIONS

Since the graphs of a one-to-one function $f$ and its inverse $f^{-1}$ are reflections of one another about the line $y = x$, it is clear geometrically that if the graph of $f$ has no breaks or holes in it, then neither does the graph of $f^{-1}$. This, and the fact that the range of $f$ is the domain of $f^{-1}$, suggests the following result, which we state without formal proof.

To paraphrase Theorem 1.6.2, *the inverse of a continuous function is continuous.*

**1.6.2 THEOREM** *If $f$ is a one-to-one function that is continuous at each point of its domain, then $f^{-1}$ is continuous at each point of its domain; that is, $f^{-1}$ is continuous at each point in the range of $f$.*

▶ **Example 2** Use Theorem 1.6.2 to prove that $\sin^{-1} x$ is continuous on the interval $[-1, 1]$.

***Solution.*** Recall that $\sin^{-1} x$ is the inverse of the restricted sine function whose domain is the interval $[-\pi/2, \pi/2]$ and whose range is the interval $[-1, 1]$ (Definition 0.4.6 and Figure 0.4.13). Since $\sin x$ is continuous on the interval $[-\pi/2, \pi/2]$, Theorem 1.6.2 implies $\sin^{-1} x$ is continuous on the interval $[-1, 1]$. ◀

Arguments similar to the solution of Example 2 show that each of the inverse trigonometric functions defined in Section 0.4 is continuous at each point of its domain.

When we introduced the exponential function $f(x) = b^x$ in Section 0.5, we assumed that its graph is a curve without breaks, gaps, or holes; that is, we assumed that the graph of $y = b^x$ is a continuous curve. This assumption and Theorem 1.6.2 imply the following theorem, which we state without formal proof.

**1.6.3 THEOREM** *Let $b > 0, b \neq 1$.*

(*a*) *The function $b^x$ is continuous on $(-\infty, +\infty)$.*

(*b*) *The function $\log_b x$ is continuous on $(0, +\infty)$.*

▶ **Example 3** Where is the function $f(x) = \dfrac{\tan^{-1} x + \ln x}{x^2 - 4}$ continuous?

***Solution.*** The fraction will be continuous at all points where the numerator and denominator are both continuous and the denominator is nonzero. Since $\tan^{-1} x$ is continuous everywhere and $\ln x$ is continuous if $x > 0$, the numerator is continuous if $x > 0$. The denominator, being a polynomial, is continuous everywhere, so the fraction will be continuous at all points where $x > 0$ and the denominator is nonzero. Thus, $f$ is continuous on the intervals $(0, 2)$ and $(2, +\infty)$. ◀

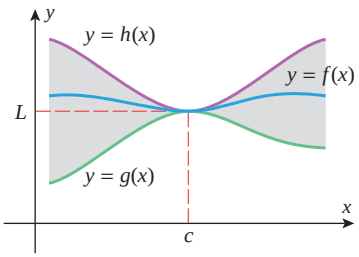
## OBTAINING LIMITS BY SQUEEZING

In Section 1.1 we used numerical evidence to conjecture that

$$\lim_{x \to 0} \frac{\sin x}{x} = 1 \tag{2}$$

However, this limit is not easy to establish with certainty. The limit is an indeterminate form of type $0/0$, and there is no simple algebraic manipulation that one can perform to obtain the limit. Later in the text we will develop general methods for finding limits of indeterminate forms, but in this particular case we can use a technique called *squeezing*.

The method of squeezing is used to prove that $f(x) \to L$ as $x \to c$ by "trapping" or "squeezing" $f$ between two functions, $g$ and $h$, whose limits as $x \to c$ are known with *certainty* to be $L$. As illustrated in Figure 1.6.2, this forces $f$ to have a limit of $L$ as well. This is the idea behind the following theorem, which we state without proof.



▲ **Figure 1.6.2**

**1.6.4 THEOREM** (*The Squeezing Theorem*) *Let $f$, $g$, and $h$ be functions satisfying*

$$g(x) \le f(x) \le h(x)$$

*for all $x$ in some open interval containing the number $c$, with the possible exception that the inequalities need not hold at $c$. If $g$ and $h$ have the same limit as $x$ approaches $c$, say*

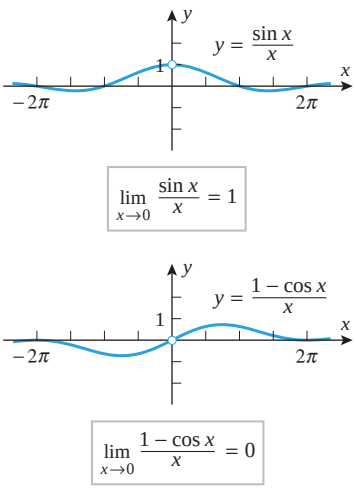
$$\lim_{x \to c} g(x) = \lim_{x \to c} h(x) = L$$

*then $f$ also has this limit as $x$ approaches $c$, that is,*

$$\lim_{x \to c} f(x) = L$$

The Squeezing Theorem also holds for one-sided limits and limits at $+\infty$ and $-\infty$. How do you think the hypotheses would change in those cases?

To illustrate how the Squeezing Theorem works, we will prove the following results, which are illustrated in Figure 1.6.3.



▲ **Figure 1.6.3**

**1.6.5 THEOREM**

$$(a) \quad \lim_{x \to 0} \frac{\sin x}{x} = 1 \qquad (b) \quad \lim_{x \to 0} \frac{1 - \cos x}{x} = 0$$

**PROOF** ***(a)*** In this proof we will interpret $x$ as an angle in radian measure, and we will assume to start that $0 < x < \pi/2$. As illustrated in Figure 1.6.4, the area of a sector with central angle $x$ and radius 1 lies between the areas of two triangles, one with area $\frac{1}{2}\tan x$ and the other with area $\frac{1}{2}\sin x$. Since the sector has area $\frac{1}{2}x$ (see marginal note), it follows that

$$\frac{1}{2}\tan x \ge \frac{1}{2}x \ge \frac{1}{2}\sin x$$

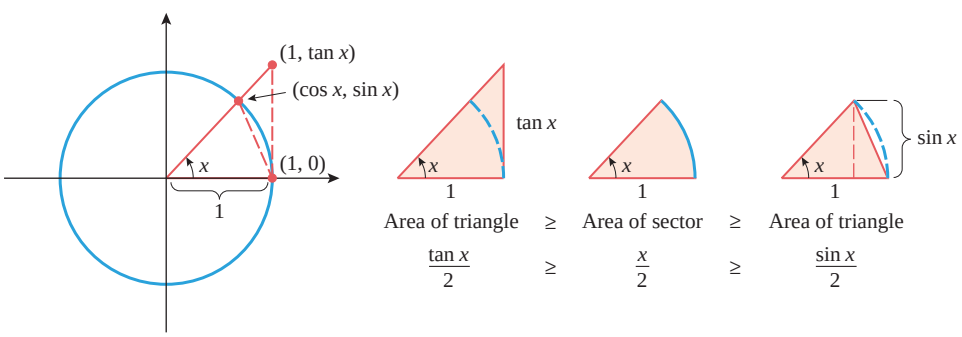
Multiplying through by $2/(\sin x)$ and using the fact that $\sin x > 0$ for $0 < x < \pi/2$, we obtain

$$\frac{1}{\cos x} \ge \frac{x}{\sin x} \ge 1$$

Next, taking reciprocals reverses the inequalities, so we obtain

$$\cos x \le \frac{\sin x}{x} \le 1 \tag{3}$$

which squeezes the function $(\sin x)/x$ between the functions $\cos x$ and 1. Although we derived these inequalities by assuming that $0 < x < \pi/2$, they also hold for $-\pi/2 < x < 0$ [since replacing $x$ by $-x$ and using the identities $\sin(-x) = -\sin x$, and $\cos(-x) = \cos x$



▶ **Figure 1.6.4**

leaves (3) unchanged]. Finally, since

$$\lim_{x\to 0}\cos x = 1 \quad \text{and} \quad \lim_{x\to 0} 1 = 1$$

the Squeezing Theorem implies that

$$\lim_{x\to 0}\frac{\sin x}{x} = 1$$

**PROOF (*b*)** For this proof we will use the limit in part (*a*), the continuity of the sine function, and the trigonometric identity $\sin^2 x = 1 - \cos^2 x$. We obtain

$$\lim_{x\to 0}\frac{1-\cos x}{x} = \lim_{x\to 0}\left[\frac{1-\cos x}{x}\cdot\frac{1+\cos x}{1+\cos x}\right] = \lim_{x\to 0}\frac{\sin^2 x}{(1+\cos x)x}$$
$$= \left(\lim_{x\to 0}\frac{\sin x}{x}\right)\left(\lim_{x\to 0}\frac{\sin x}{1+\cos x}\right) = (1)\left(\frac{0}{1+1}\right) = 0 \quad \blacksquare$$

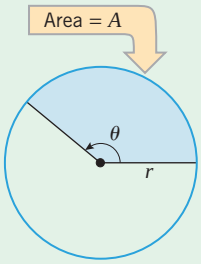
Recall that the area $A$ of a sector of radius $r$ and central angle $\theta$ is

$$A = \frac{1}{2}r^2\theta$$

This can be derived from the relationship

$$\frac{A}{\pi r^2} = \frac{\theta}{2\pi}$$

which states that the area of the sector is to the area of the circle as the central angle of the sector is to the central angle of the circle.



### ▶ Example 4

Find

(a) $\lim_{x\to 0}\dfrac{\tan x}{x}$ (b) $\lim_{\theta\to 0}\dfrac{\sin 2\theta}{\theta}$ (c) $\lim_{x\to 0}\dfrac{\sin 3x}{\sin 5x}$

***Solution (a).***

$$\lim_{x\to 0}\frac{\tan x}{x} = \lim_{x\to 0}\left(\frac{\sin x}{x}\cdot\frac{1}{\cos x}\right) = \left(\lim_{x\to 0}\frac{\sin x}{x}\right)\left(\lim_{x\to 0}\frac{1}{\cos x}\right) = (1)(1) = 1$$

***Solution (b).*** The trick is to multiply and divide by 2, which will make the denominator the same as the argument of the sine function [just as in Theorem 1.6.5(*a*)]:

$$\lim_{\theta\to 0}\frac{\sin 2\theta}{\theta} = \lim_{\theta\to 0} 2\cdot\frac{\sin 2\theta}{2\theta} = 2\lim_{\theta\to 0}\frac{\sin 2\theta}{2\theta}$$

Now make the substitution $x = 2\theta$, and use the fact that $x\to 0$ as $\theta\to 0$. This yields

$$\lim_{\theta\to 0}\frac{\sin 2\theta}{\theta} = 2\lim_{\theta\to 0}\frac{\sin 2\theta}{2\theta} = 2\lim_{x\to 0}\frac{\sin x}{x} = 2(1) = 2$$

**TECHNOLOGY MASTERY**

Use a graphing utility to confirm the limits in Example 4, and if you have a CAS, use it to obtain the limits.

***Solution (c).***

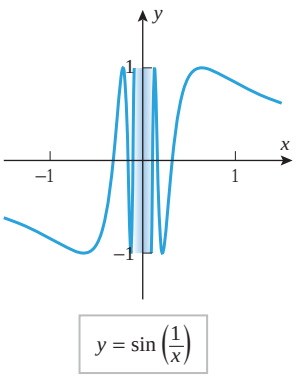
$$\lim_{x\to 0}\frac{\sin 3x}{\sin 5x} = \lim_{x\to 0}\frac{\dfrac{\sin 3x}{x}}{\dfrac{\sin 5x}{x}} = \lim_{x\to 0}\frac{3\cdot\dfrac{\sin 3x}{3x}}{5\cdot\dfrac{\sin 5x}{5x}} = \frac{3\cdot 1}{5\cdot 1} = \frac{3}{5} \quad \blacktriangleleft$$

### ▶ Example 5

Discuss the limits

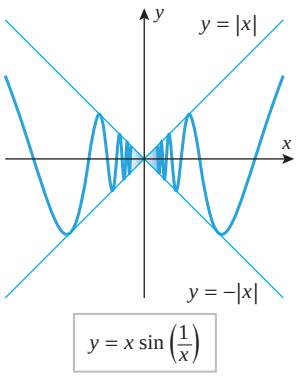
(a) $\lim_{x\to 0}\sin\left(\dfrac{1}{x}\right)$ (b) $\lim_{x\to 0} x\sin\left(\dfrac{1}{x}\right)$

***Solution (a).*** Let us view $1/x$ as an angle in radian measure. As $x\to 0^+$, the angle $1/x$ approaches $+\infty$, so the values of $\sin(1/x)$ keep oscillating between $-1$ and 1 without approaching a limit. Similarly, as $x\to 0^-$, the angle $1/x$ approaches $-\infty$, so again the values of $\sin(1/x)$ keep oscillating between $-1$ and 1 without approaching a limit. These conclusions are consistent with the graph shown in Figure 1.6.5. Note that the oscillations become more and more rapid as $x\to 0$ because $1/x$ increases (or decreases) more and more rapidly as $x$ approaches 0.



▲ **Figure 1.6.5**

Confirm (4) by considering the cases $x > 0$ and $x < 0$ separately.



▲ Figure 1.6.6

***Solution (b).*** Since

$$-1 \le \sin\left(\frac{1}{x}\right) \le 1$$

it follows that if $x \neq 0$, then

$$-|x| \le x \sin\left(\frac{1}{x}\right) \le |x| \tag{4}$$

Since $|x| \to 0$ as $x \to 0$, the inequalities in (4) and the Squeezing Theorem imply that

$$\lim_{x \to 0} x \sin\left(\frac{1}{x}\right) = 0$$

This is consistent with the graph shown in Figure 1.6.6. ◀

**REMARK** It follows from part (b) of this example that the function

$$f(x) = \begin{cases} x \sin(1/x), & x \neq 0 \\ 0, & x = 0 \end{cases}$$

is continuous at $x = 0$, since the value of the function and the value of the limit are the same at 0. This shows that the behavior of a function can be very complex in the vicinity of $x = c$, even though the function is continuous at $c$.

## ✔ QUICK CHECK EXERCISES 1.6 (See page 128 for answers.)

**1.** In each part, is the given function continuous on the interval $[0, \pi/2)$?
(a) $\sin x$ (b) $\cos x$ (c) $\tan x$ (d) $\csc x$

**2.** Evaluate
(a) $\lim_{x \to 0} \dfrac{\sin x}{x}$
(b) $\lim_{x \to 0} \dfrac{1 - \cos x}{x}$.

**3.** Suppose a function $f$ has the property that for all real numbers $x$

$$3 - |x| \le f(x) \le 3 + |x|$$

From this we can conclude that $f(x) \to$ _____ as $x \to$ _____.

**4.** In each part, give the largest interval on which the function is continuous.
(a) $e^x$ (b) $\ln x$ (c) $\sin^{-1} x$ (d) $\tan^{-1} x$

## EXERCISE SET 1.6 Graphing Utility

**1–8** Find the discontinuities, if any. ■

**1.** $f(x) = \sin(x^2 - 2)$

**2.** $f(x) = \cos\left(\dfrac{x}{x - \pi}\right)$

**3.** $f(x) = |\cot x|$

**4.** $f(x) = \sec x$

**5.** $f(x) = \csc x$

**59.** $\lim_{x\to 0}\frac{\sin^{-1}5x}{x}$

**60.** $\lim_{x\to 1}\frac{\sin^{-1}(x-1)}{x^2-1}$

## FOCUS ON CONCEPTS

**61.** Use the Squeezing Theorem to show that

$$\lim_{x\to 0} x\cos\frac{50\pi}{x}=0$$

and illustrate the principle involved by using a graphing utility to graph the equations $y=|x|$, $y=-|x|$, and $y=x\cos(50\pi/x)$ on the same screen in the window $[-1,1]\times[-1,1]$.

**62.** Use the Squeezing Theorem to show that

$$\lim_{x\to 0} x^2\sin\left(\frac{50\pi}{\sqrt[3]{x}}\right)=0$$

and illustrate the principle involved by using a graphing utility to graph the equations $y=x^2$, $y=-x^2$, and $y=x^2\sin(50\pi/\sqrt[3]{x})$ on the same screen in the window $[-0.5,0.5]\times[-0.25,0.25]$.

**63.** In Example 5 we used the Squeezing Theorem to prove that

$$\lim_{x\to 0} x\sin\left(\frac{1}{x}\right)=0$$

Why couldn't we have obtained the same result by writing

$$\lim_{x\to 0} x\sin\left(\frac{1}{x}\right)=\lim_{x\to 0} x\cdot\lim_{x\to 0}\sin\left(\frac{1}{x}\right)$$
$$=0\cdot\lim_{x\to 0}\sin\left(\frac{1}{x}\right)=0?$$

**64.** Sketch the graphs of the curves $y=1-x^2$, $y=\cos x$, and $y=f(x)$, where $f$ is a function that satisfies the inequalities

$$1-x^2\le f(x)\le\cos x$$

for all $x$ in the interval $(-\pi/2,\pi/2)$. What can you say about the limit of $f(x)$ as $x\to 0$? Explain.

**65.** Sketch the graphs of the curves $y=1/x$, $y=-1/x$, and $y=f(x)$, where $f$ is a function that satisfies the inequalities

$$-\frac{1}{x}\le f(x)\le\frac{1}{x}$$

for all $x$ in the interval $[1,+\infty)$. What can you say about the limit of $f(x)$ as $x\to+\infty$? Explain your reasoning.

**66.** Draw pictures analogous to Figure 1.6.2 that illustrate the Squeezing Theorem for limits of the forms $\lim_{x\to+\infty} f(x)$ and $\lim_{x\to-\infty} f(x)$.

**67.** (a) Use the Intermediate-Value Theorem to show that the equation $x=\cos x$ has at least one solution in the interval $[0,\pi/2]$.

(b) Show graphically that there is exactly one solution in the interval.

(c) Approximate the solution to three decimal places.

**68.** (a) Use the Intermediate-Value Theorem to show that the equation $x+\sin x=1$ has at least one solution in the interval $[0,\pi/6]$.

(b) Show graphically that there is exactly one solution in the interval.

(c) Approximate the solution to three decimal places.

**69.** In the study of falling objects near the surface of the Earth, the ***acceleration g due to gravity*** is commonly taken to be a constant 9.8 m/s$^2$. However, the elliptical shape of the Earth and other factors cause variations in this value that depend on latitude. The following formula, known as the World Geodetic System 1984 (WGS 84) Ellipsoidal Gravity Formula, is used to predict the value of $g$ at a latitude of $\phi$ degrees (either north or south of the equator):

$$g=9.7803253359\frac{1+0.0019318526461\sin^2\phi}{\sqrt{1-0.0066943799901\sin^2\phi}}\ \text{m/s}^2$$

(*cont.*)

(a) Use a graphing utility to graph the curve $y = g(\phi)$ for $0° \le \phi \le 90°$. What do the values of $g$ at $\phi = 0°$ and at $\phi = 90°$ tell you about the WGS 84 ellipsoid model for the Earth?

(b) Show that $g = 9.8\ \text{m/s}^2$ somewhere between latitudes of $38°$ and $39°$.

**70. Writing** In your own words, explain the *practical value* of the Squeezing Theorem.

**71. Writing** A careful examination of the proof of Theorem 1.6.5 raises the issue of whether the proof might actually be a circular argument! Read the article "A Circular Argument" by Fred Richman in the March 1993 issue of *The College Mathematics Journal*, and write a short report on the author's principal points.

**3.** (a) Approximate the value for the limit

$$\lim_{x\to 0} \frac{3^x - 2^x}{x}$$

to three decimal places by constructing an appropriate table of values.

(b) Confirm your approximation using graphical evidence.

C **4.** Approximate

$$\lim_{x\to 3} \frac{2^x - 8}{x - 3}$$

both by looking at a graph and by calculating values for some appropriate choices of $x$. Compare your answer with the value produced by a CAS.

**5–10** Find the limits. ■

**5.** $\lim_{x\to -1} \dfrac{x^3 - x^2}{x - 1}$ **6.** $\lim_{x\to 1} \dfrac{x^3 - x^2}{x - 1}$

**7.** $\lim_{x\to -3} \dfrac{3x + 9}{x^2 + 4x + 3}$ **8.** $\lim_{x\to 2^-} \dfrac{x + 2}{x - 2}$

**9.** $\lim_{x\to +\infty} \dfrac{(2x-1)^5}{(3x^2 + 2x - 7)(x^3 - 9x)}$

**10.** $\lim_{x\to 0} \dfrac{\sqrt{x^2 + 4} - 2}{x^2}$

**11.** In each part, find the horizontal asymptotes, if any.

(a) $y = \dfrac{2x - 7}{x^2 - 4x}$ (b) $y = \dfrac{x^3 - x^2 + 10}{3x^2 - 4x}$

(c) $y = \dfrac{2x^2 - 6}{x^2 + 5x}$

**12.** In each part, find $\lim_{x\to a} f(x)$, if it exists, where $a$ is replaced by $0, 5^+, -5^-, -5, 5, -\infty$, and $+\infty$.

(a) $f(x) = \sqrt{5 - x}$

(b) $f(x) = \begin{cases} (x-5)/|x-5|, & x \ne 5 \\ 0, & x = 5 \end{cases}$

**13–20** Find the limits. ■

**13.** $\lim_{x\to 0} \dfrac{\sin 3x}{\tan 3x}$ **14.** $\lim_{x\to 0} \dfrac{x \sin x}{1 - \cos x}$

**15.** $\lim_{x\to 0} \dfrac{3x - \sin(kx)}{x}$, $k \ne 0$

**16.** $\lim_{\theta\to 0} \tan\left(\dfrac{1 - \cos\theta}{\theta}\right)$

**17.** $\lim_{t\to \pi/2^+} e^{\tan t}$ **18.** $\lim_{\theta\to 0^+} \ln(\sin 2\theta) - \ln(\tan\theta)$

**19.** $\lim_{x \to +\infty} \left(1 + \frac{3}{x}\right)^{-x}$ **20.** $\lim_{x \to +\infty} \left(1 + \frac{a}{x}\right)^{bx}, \quad a, b > 0$

**21.** If \$1000 is invested in an account that pays 7% interest compounded $n$ times each year, then in 10 years there will be $1000(1 + 0.07/n)^{10n}$ dollars in the account. How much money will be in the account in 10 years if the interest is compounded quarterly ($n = 4$)? Monthly ($n = 12$)? Daily ($n = 365$)? Determine the amount of money that will be in the account in 10 years if the interest is compounded *continuously*, that is, as $n \to +\infty$.

**22.** (a) Write a paragraph or two that describes how the limit of a function can fail to exist at $x = a$, and accompany your description with some specific examples.
(b) Write a paragraph or two that describes how the limit of a function can fail to exist as $x \to +\infty$ or $x \to -\infty$, and accompany your description with some specific examples.
(c) Write a paragraph or two that describes how a function can fail to be continuous at $x = a$, and accompany your description with some specific examples.

**23.** (a) Find a formula for a rational function that has a vertical asymptote at $x = 1$ and a horizontal asymptote at $y = 2$.
(b) Check your work by using a graphing utility to graph the function.

**24.** Paraphrase the $\epsilon$-$\delta$ definition for $\lim_{x \to a} f(x) = L$ in terms of a graphing utility viewing window centered at the point $(a, L)$.

**25.** Suppose that $f(x)$ is a function and that for any given $\epsilon > 0$, the condition $0 < |x - 2| < \frac{3}{4}\epsilon$ guarantees that $|f(x) - 5| < \epsilon$.
(a) What limit is described by this statement?
(b) Find a value of $\delta$ such that $0 < |x - 2| < \delta$ guarantees that $|8f(x) - 40| < 0.048$.

**26.** The limit

$$\lim_{x \to 0} \frac{\sin x}{x} = 1$$

ensures that there is a number $\delta$ such that

$$\left| \frac{\sin x}{x} - 1 \right| < 0.001$$

if $0 < |x| < \delta$. Estimate the largest such $\delta$.

**27.** In each part, a positive number $\epsilon$ and the limit $L$ of a function $f$ at $a$ are given. Find a number $\delta$ such that $|f(x) - L| < \epsilon$ if $0 < |x - a| < \delta$.
(a) $\lim_{x \to 2} (4x - 7) = 1; \ \epsilon = 0.01$
(b) $\lim_{x \to 3/2} \frac{4x^2 - 9}{2x - 3} = 6; \ \epsilon = 0.05$
(c) $\lim_{x \to 4} x^2 = 16; \ \epsilon = 0.001$

**28.** Use Definition 1.4.1 to prove the stated limits are correct.
(a) $\lim_{x \to 2} (4x - 7) = 1$ (b) $\lim_{x \to 3/2} \frac{4x^2 - 9}{2x - 3} = 6$

**29.** Suppose that $f$ is continuous at $x_0$ and that $f(x_0) > 0$. Give either an $\epsilon$-$\delta$ proof or a convincing verbal argument to show that there must be an open interval containing $x_0$ on which $f(x) > 0$.

**30.** (a) Let

$$f(x) = \frac{\sin x - \sin 1}{x - 1}$$

Approximate $\lim_{x \to 1} f(x)$ by graphing $f$ and calculating values for some appropriate choices of $x$.
(b) Use the identity

$$\sin \alpha - \sin \beta = 2 \sin \frac{\alpha - \beta}{2} \cos \frac{\alpha + \beta}{2}$$

to find the exact value of $\lim_{x \to 1} f(x)$.

**31.** Find values of $x$, if any, at which the given function is not continuous.
(a) $f(x) = \frac{x}{x^2 - 1}$ (b) $f(x) = |x^3 - 2x^2|$
(c) $f(x) = \frac{x + 3}{|x^2 + 3x|}$

**32.** Determine where $f$ is continuous.
(a) $f(x) = \frac{x}{|x| - 3}$ (b) $f(x) = \cos^{-1}\left(\frac{1}{x}\right)$
(c) $f(x) = e^{\ln x}$

**33.** Suppose that

$$f(x) = \begin{cases} -x^4 + 3, & x \le 2 \\ x^2 + 9, & x > 2 \end{cases}$$

Is $f$ continuous everywhere? Justify your conclusion.

**34.** One dictionary describes a continuous function as "one whose value at each point is closely approached by its values at neighboring points."
(a) How would you explain the meaning of the terms "neighboring points" and "closely approached" to a nonmathematician?
(b) Write a paragraph that explains why the dictionary definition is consistent with Definition 1.5.1.

**35.** Show that the conclusion of the Intermediate-Value Theorem may be false if $f$ is not continuous on the interval $[a, b]$.

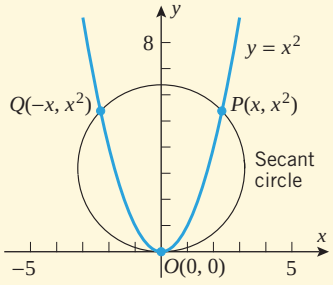
**36.** Suppose that $f$ is continuous on the interval $[0, 1]$, that $f(0) = 2$, and that $f$ has no zeros in the interval. Prove that $f(x) > 0$ for all $x$ in $[0, 1]$.

**37.** Show that the equation $x^4 + 5x^3 + 5x - 1 = 0$ has at least two real solutions in the interval $[-6, 2]$.

## CHAPTER 1 MAKING CONNECTIONS

In Section 1.1 we developed the notion of a tangent line to a graph at a given point by considering it as a limiting position of secant lines through that point (Figure 1.1.4*a*). In these exercises we will develop an analogous idea in which secant lines are replaced by "secant circles" and the tangent line is replaced by a "tangent circle" (called the ***osculating circle***). We begin with the graph of $y = x^2$.

**1.** Recall that there is a unique circle through any three noncollinear points in the plane. For any positive real number $x$, consider the unique "secant circle" that passes through the fixed point $O(0, 0)$ and the variable points $Q(-x, x^2)$ and $P(x, x^2)$ (see the accompanying figure). Use plane geometry to explain why the center of this circle is the intersection of the $y$-axis and the perpendicular bisector of segment $OP$.

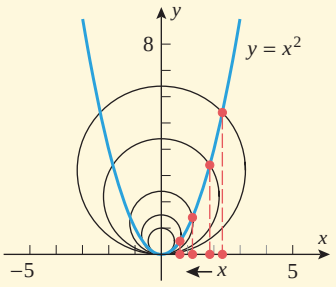


◀ **Figure Ex-1**

**2.** (a) Let $(0, C(x))$ denote the center of the circle in Exercise 1 and show that

$$C(x) = \tfrac{1}{2}x^2 + \tfrac{1}{2}$$

(b) Show that as $x \to 0^+$, the secant circles approach a limiting position given by the circle that passes through the origin and is centered at $\left(0, \frac{1}{2}\right)$. As shown in the accompanying figure, this circle is the osculating circle to the graph of $y = x^2$ at the origin.



◀ **Figure Ex-2**

**3.** Show that if we replace the curve $y = x^2$ by the curve $y = f(x)$, where $f$ is an even function, then the formula for $C(x)$ becomes

$$C(x) = \frac{1}{2}\left[f(0) + f(x) + \frac{x^2}{f(x) - f(0)}\right]$$

[Here we assume that $f(x) \neq f(0)$ for positive values of $x$ close to 0.] If $\lim_{x \to 0^+} C(x) = L \neq f(0)$, then we define the osculating circle to the curve $y = f(x)$ at $(0, f(0))$ to be the unique circle through $(0, f(0))$ with center $(0, L)$. If $C(x)$ does not have a finite limit different from $f(0)$ as $x \to 0^+$, then we say that the curve has no osculating circle at $(0, f(0))$.

**4.** In each part, determine the osculating circle to the curve $y = f(x)$ at $(0, f(0))$, if it exists.

(a) $f(x) = 4x^2$ (b) $f(x) = x^2 \cos x$

(c) $f(x) = |x|$ (d) $f(x) = x \sin x$

(e) $f(x) = \cos x$

(f) $f(x) = x^2 g(x)$, where $g(x)$ is an even continuous function with $g(0) \neq 0$

(g) $f(x) = x^4$

# 2 THE DERIVATIVE

Photo by Kirby Lee/WireImage/Getty Images

*One of the crowning achievements of calculus is its ability to capture continuous motion mathematically, allowing that motion to be analyzed instant by instant.*

Many real-world phenomena involve changing quantities—the speed of a rocket, the inflation of currency, the number of bacteria in a culture, the shock intensity of an earthquake, the voltage of an electrical signal, and so forth. In this chapter we will develop the concept of a "derivative," which is the mathematical tool for studying the rate at which one quantity changes relative to another. The study of rates of change is closely related to the geometric concept of a tangent line to a curve, so we will also be discussing the general definition of a tangent line and methods for finding its slope and equation.

## 2.1 TANGENT LINES AND RATES OF CHANGE

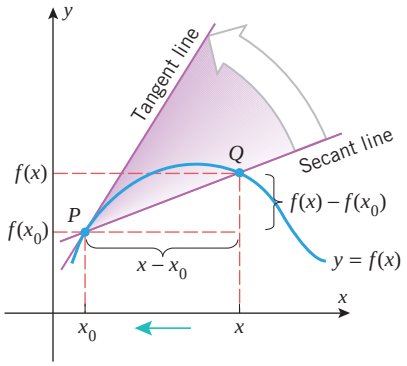
*In this section we will discuss three ideas: tangent lines to curves, the velocity of an object moving along a line, and the rate at which one variable changes relative to another. Our goal is to show how these seemingly unrelated ideas are, in actuality, closely linked.*

### TANGENT LINES

In Example 1 of Section 1.1, we showed how the notion of a limit could be used to find an equation of a tangent line to a curve. At that stage in the text we did not have precise definitions of tangent lines and limits to work with, so the argument was intuitive and informal. However, now that limits have been defined precisely, we are in a position to give a mathematical definition of the tangent line to a curve $y = f(x)$ at a point $P(x_0, f(x_0))$ on the curve. As illustrated in Figure 2.1.1, consider a point $Q(x, f(x))$ on the curve that is distinct from $P$, and compute the slope $m_{PQ}$ of the secant line through $P$ and $Q$:

$$m_{PQ} = \frac{f(x) - f(x_0)}{x - x_0}$$

If we let $x$ approach $x_0$, then the point $Q$ will move along the curve and approach the point $P$. If the secant line through $P$ and $Q$ approaches a limiting position as $x \to x_0$, then we will regard that position to be the position of the tangent line at $P$. Stated another way, if the slope $m_{PQ}$ of the secant line through $P$ and $Q$ approaches a limit as $x \to x_0$, then we regard that limit to be the slope $m_{\text{tan}}$ of the tangent line at $P$. Thus, we make the following definition.



▶ **Figure 2.1.1**

**2.1.1 DEFINITION** Suppose that $x_0$ is in the domain of the function $f$. The ***tangent line*** to the curve $y = f(x)$ at the point $P(x_0, f(x_0))$ is the line with equation

$$y - f(x_0) = m_{\tan}(x - x_0)$$

where

$$m_{\tan} = \lim_{x \to x_0} \frac{f(x) - f(x_0)}{x - x_0} \tag{1}$$

provided the limit exists. For simplicity, we will also call this the tangent line to $y = f(x)$ at $x_0$.

▶ **Example 1** Use Definition 2.1.1 to find an equation for the tangent line to the parabola $y = x^2$ at the point $P\,(1, 1)$, and confirm the result agrees with that obtained in Example 1 of Section 1.1.

***Solution.*** Applying Formula (1) with $f(x) = x^2$ and $x_0 = 1$, we have

$$\begin{aligned} m_{\tan} &= \lim_{x \to 1} \frac{f(x) - f(1)}{x - 1} \\ &= \lim_{x \to 1} \frac{x^2 - 1}{x - 1} \\ &= \lim_{x \to 1} \frac{(x - 1)(x + 1)}{x - 1} = \lim_{x \to 1} (x + 1) = 2 \end{aligned}$$

Thus, the tangent line to $y = x^2$ at $(1, 1)$ has equation

$$y - 1 = 2(x - 1) \quad \text{or equivalently} \quad y = 2x - 1$$

which agrees with Example 1 of Section 1.1. ◀

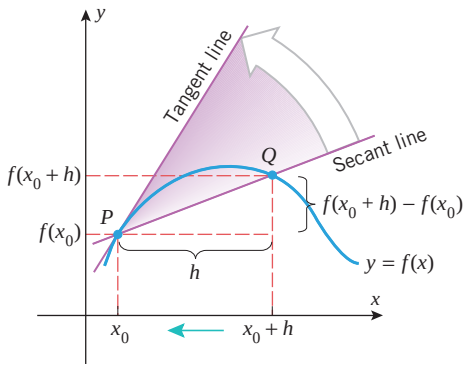
There is an alternative way of expressing Formula (1) that is commonly used. If we let $h$ denote the difference

$$h = x - x_0$$

then the statement that $x \to x_0$ is equivalent to the statement $h \to 0$, so we can rewrite (1) in terms of $x_0$ and $h$ as

$$m_{\tan} = \lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h} \tag{2}$$

Figure 2.1.2 shows how Formula (2) expresses the slope of the tangent line as a limit of slopes of secant lines.



▶ **Figure 2.1.2**

▶ **Example 2** Compute the slope in Example 1 using Formula (2).

Formulas (1) and (2) for $m_{\tan}$ usually lead to indeterminate forms of type $0/0$, so you will generally need to perform algebraic simplifications or use other methods to determine limits of such indeterminate forms.

***Solution.*** Applying Formula (2) with $f(x) = x^2$ and $x_0 = 1$, we obtain

$$m_{\tan} = \lim_{h \to 0} \frac{f(1+h) - f(1)}{h}$$

$$= \lim_{h \to 0} \frac{(1+h)^2 - 1^2}{h}$$

$$= \lim_{h \to 0} \frac{1 + 2h + h^2 - 1}{h} = \lim_{h \to 0} (2 + h) = 2$$

which agrees with the slope found in Example 1. ◀

▶ **Example 3** Find an equation for the tangent line to the curve $y = 2/x$ at the point $(2, 1)$ on this curve.

***Solution.*** First, we will find the slope of the tangent line by applying Formula (2) with $f(x) = 2/x$ and $x_0 = 2$. This yields

$$m_{\tan} = \lim_{h \to 0} \frac{f(2+h) - f(2)}{h}$$

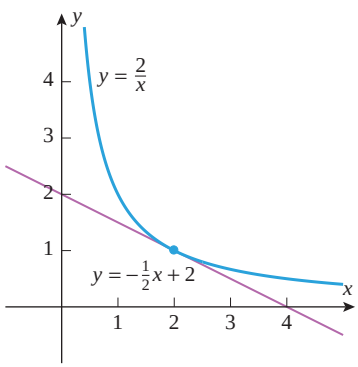
$$= \lim_{h \to 0} \frac{\dfrac{2}{2+h} - 1}{h} = \lim_{h \to 0} \frac{\left(\dfrac{2 - (2+h)}{2+h}\right)}{h}$$

$$= \lim_{h \to 0} \frac{-h}{h(2+h)} = -\left(\lim_{h \to 0} \frac{1}{2+h}\right) = -\frac{1}{2}$$

Thus, an equation of the tangent line at $(2, 1)$ is

$$y - 1 = -\tfrac{1}{2}(x - 2) \quad \text{or equivalently} \quad y = -\tfrac{1}{2}x + 2$$

(see Figure 2.1.3). ◀



▲ **Figure 2.1.3**

▶ **Example 4** Find the slopes of the tangent lines to the curve $y = \sqrt{x}$ at $x_0 = 1$, $x_0 = 4$, and $x_0 = 9$.

***Solution.*** We could compute each of these slopes separately, but it will be more efficient to find the slope for a general value of $x_0$ and then substitute the specific numerical values. Proceeding in this way we obtain

$$\begin{aligned} m_{\tan} &= \lim_{h\to 0} \frac{f(x_0+h)-f(x_0)}{h} \\ &= \lim_{h\to 0} \frac{\sqrt{x_0+h}-\sqrt{x_0}}{h} \\ &= \lim_{h\to 0} \frac{\sqrt{x_0+h}-\sqrt{x_0}}{h} \cdot \frac{\sqrt{x_0+h}+\sqrt{x_0}}{\sqrt{x_0+h}+\sqrt{x_0}} \\ &= \lim_{h\to 0} \frac{x_0+h-x_0}{h(\sqrt{x_0+h}+\sqrt{x_0})} \\ &= \lim_{h\to 0} \frac{h}{h(\sqrt{x_0+h}+\sqrt{x_0})} \\ &= \lim_{h\to 0} \frac{1}{\sqrt{x_0+h}+\sqrt{x_0}} = \frac{1}{2\sqrt{x_0}} \end{aligned}$$

Rationalize the numerator to help eliminate the indeterminate form of the limit.

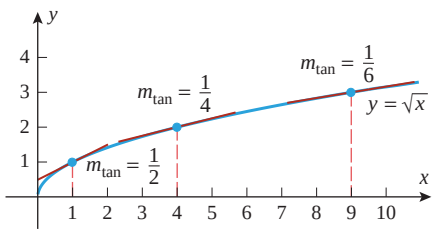
The slopes at $x_0 = 1, 4$, and 9 can now be obtained by substituting these values into our general formula for $m_{\tan}$. Thus,

$$\text{slope at } x_0 = 1\text{: } \frac{1}{2\sqrt{1}} = \frac{1}{2}$$

$$\text{slope at } x_0 = 4\text{: } \frac{1}{2\sqrt{4}} = \frac{1}{4}$$

$$\text{slope at } x_0 = 9\text{: } \frac{1}{2\sqrt{9}} = \frac{1}{6}$$

(see Figure 2.1.4). ◀



▶ **Figure 2.1.4**

## VELOCITY

Carlos Santa Maria/iStockphoto

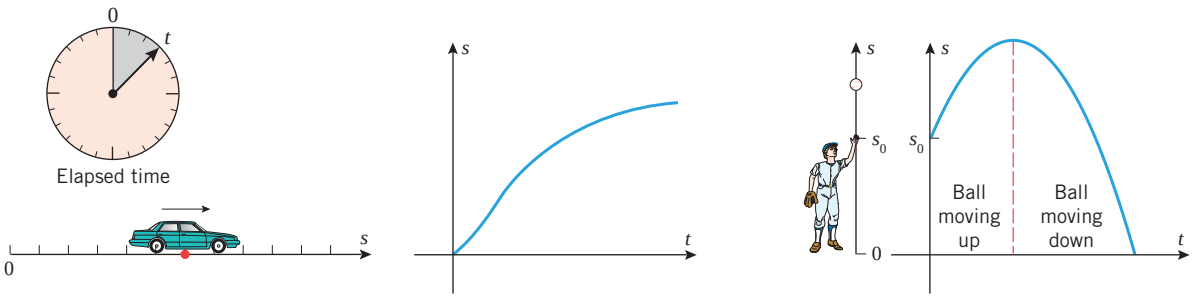
*The velocity of an airplane describes its speed and direction.*

One of the important themes in calculus is the study of motion. To describe the motion of an object completely, one must specify its ***speed*** (how fast it is going) and the direction in which it is moving. The speed and the direction of motion together comprise what is called the ***velocity*** of the object. For example, knowing that the speed of an aircraft is 500 mi/h tells us how fast it is going, but not which way it is moving. In contrast, knowing that the velocity of the aircraft is 500 mi/h *due south* pins down the speed and the direction of motion.

Later, we will study the motion of objects that move along curves in two- or three-dimensional space, but for now we will only consider motion along a line; this is called ***rectilinear motion***. Some examples are a piston moving up and down in a cylinder, a race

car moving along a straight track, an object dropped from the top of a building and falling straight down, a ball thrown straight up and then falling down along the same line, and so forth.

For computational purposes, we will assume that a particle in rectilinear motion moves along a coordinate line, which we will call the $s$-axis. A graphical description of rectilinear motion along an $s$-axis can be obtained by making a plot of the $s$-coordinate of the particle versus the elapsed time $t$ from starting time $t = 0$. This is called the ***position versus time curve*** for the particle. Figure 2.1.5 shows two typical position versus time curves. The first is for a car that starts at the origin and moves only in the positive direction of the $s$-axis. In this case $s$ increases as $t$ increases. The second is for a ball that is thrown straight up in the positive direction of an $s$-axis from some initial height $s_0$ and then falls straight down in the negative direction. In this case $s$ increases as the ball moves up and decreases as it moves down.



▲ **Figure 2.1.5**

If a particle in rectilinear motion moves along an $s$-axis so that its position coordinate function of the elapsed time $t$ is

$$s = f(t) \tag{3}$$

then $f$ is called the ***position function of the particle***; the graph of (3) is the position versus time curve. The ***average velocity*** of the particle over a time interval $[t_0, t_0 + h]$, $h > 0$, is defined to be

$$v_{\text{ave}} = \frac{\text{change in position}}{\text{time elapsed}} = \frac{f(t_0 + h) - f(t_0)}{h} \tag{4}$$

Show that (4) is also correct for a time interval $[t_0 + h, t_0]$, $h < 0$.

The change in position

$$f(t_0 + h) - f(t_0)$$

is also called the ***displacement*** of the particle over the time interval between $t_0$ and $t_0 + h$.

▶ **Example 5** Suppose that $s = f(t) = 1 + 5t - 2t^2$ is the position function of a particle, where $s$ is in meters and $t$ is in seconds. Find the average velocities of the particle over the time intervals (a) [0, 2] and (b) [2, 3].

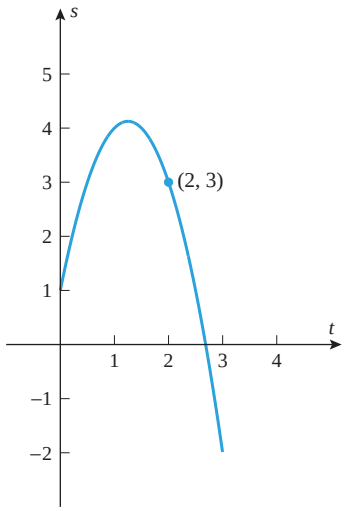
***Solution (a).*** Applying (4) with $t_0 = 0$ and $h = 2$, we see that the average velocity is

$$v_{\text{ave}} = \frac{f(t_0 + h) - f(t_0)}{h} = \frac{f(2) - f(0)}{2} = \frac{3 - 1}{2} = \frac{2}{2} = 1 \text{ m/s}$$

***Solution (b).*** Applying (4) with $t_0 = 2$ and $h = 1$, we see that the average velocity is

$$v_{\text{ave}} = \frac{f(t_0 + h) - f(t_0)}{h} = \frac{f(3) - f(2)}{1} = \frac{-2 - 3}{1} = \frac{-5}{1} = -5 \text{ m/s} \quad ◀$$

For a particle in rectilinear motion, average velocity describes its behavior over an *interval* of time. We are interested in the particle's "instantaneous velocity," which describes



▲ Figure 2.1.6

**Table 2.1.1**

| TIME INTERVAL | AVERAGE VELOCITY (m/s) |
|---|---|
| $2.0 \le t \le 3.0$ | −5 |
| $2.0 \le t \le 2.1$ | −3.2 |
| $2.0 \le t \le 2.01$ | −3.02 |
| $2.0 \le t \le 2.001$ | −3.002 |
| $2.0 \le t \le 2.0001$ | −3.0002 |

Note the negative values for the velocities in Example 6. This is consistent with the fact that the object is moving in the negative direction along the $s$-axis.

its behavior at a specific *instant* in time. Formula (4) is not directly applicable for computing instantaneous velocity because the "time elapsed" at a specific instant is zero, so (4) is undefined. One way to circumvent this problem is to compute average velocities for small time intervals between $t = t_0$ and $t = t_0 + h$. These average velocities may be viewed as approximations to the "instantaneous velocity" of the particle at time $t_0$. If these average velocities have a limit as $h$ approaches zero, then we can take that limit to be the *instantaneous velocity* of the particle at time $t_0$. Here is an example.

▶ **Example 6** Consider the particle in Example 5, whose position function is

$$s = f(t) = 1 + 5t - 2t^2$$

The position of the particle at time $t = 2$ s is $s = 3$ m (Figure 2.1.6). Find the particle's instantaneous velocity at time $t = 2$ s.

***Solution.*** As a first approximation to the particle's instantaneous velocity at time $t = 2$ s, let us recall from Example 5(b) that the average velocity over the time interval from $t = 2$ to $t = 3$ is $v_{\text{ave}} = -5$ m/s. To improve on this initial approximation we will compute the average velocity over a succession of smaller and smaller time intervals. We leave it to you to verify the results in Table 2.1.1. The average velocities in this table appear to be approaching a limit of $-3$ m/s, providing strong evidence that the instantaneous velocity at time $t = 2$ s is $-3$ m/s. To confirm this analytically, we start by computing the object's average velocity over a general time interval between $t = 2$ and $t = 2 + h$ using Formula (4):

$$v_{\text{ave}} = \frac{f(2+h) - f(2)}{h} = \frac{[1 + 5(2+h) - 2(2+h)^2] - 3}{h}$$

The object's instantaneous velocity at time $t = 2$ is calculated as a limit as $h \to 0$:

$$\begin{aligned} \text{instantaneous velocity} &= \lim_{h \to 0} \frac{[1 + 5(2+h) - 2(2+h)^2] - 3}{h} \\ &= \lim_{h \to 0} \frac{-2 + (10 + 5h) - (8 + 8h + 2h^2)}{h} \\ &= \lim_{h \to 0} \frac{-3h - 2h^2}{h} = \lim_{h \to 0} (-3 - 2h) = -3 \end{aligned}$$

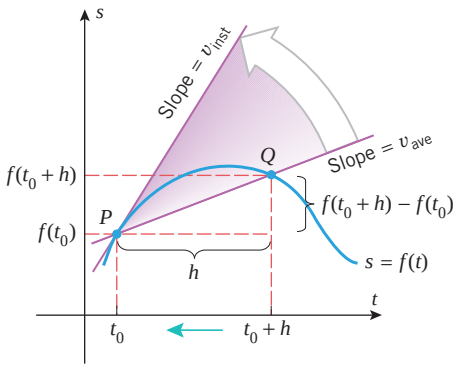
This confirms our numerical conjecture that the instantaneous velocity after 2 s is $-3$ m/s. ◀

Consider a particle in rectilinear motion with position function $s = f(t)$. Motivated by Example 6, we define the instantaneous velocity $v_{\text{inst}}$ of the particle at time $t_0$ to be the limit as $h \to 0$ of its average velocities $v_{\text{ave}}$ over time intervals between $t = t_0$ and $t = t_0 + h$. Thus, from (4) we obtain

$$v_{\text{inst}} = \lim_{h \to 0} \frac{f(t_0 + h) - f(t_0)}{h} \tag{5}$$

Confirm the solution to Example 5(b) by computing the slope of an appropriate secant line.

Geometrically, the average velocity $v_{\text{ave}}$ between $t = t_0$ and $t = t_0 + h$ is the slope of the secant line through points $P(t_0, f(t_0))$ and $Q(t_0 + h, f(t_0 + h))$ on the position versus time curve, and the instantaneous velocity $v_{\text{inst}}$ at time $t_0$ is the slope of the tangent line to the position versus time curve at the point $P(t_0, f(t_0))$ (Figure 2.1.7).

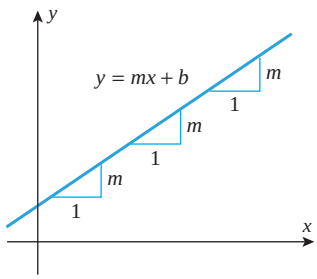


▶ **Figure 2.1.7**

## SLOPES AND RATES OF CHANGE

Velocity can be viewed as *rate of change*—the rate of change of position with respect to time. Rates of change occur in other applications as well. For example:

- A microbiologist might be interested in the rate at which the number of bacteria in a colony changes with time.
- An engineer might be interested in the rate at which the length of a metal rod changes with temperature.
- An economist might be interested in the rate at which production cost changes with the quantity of a product that is manufactured.
- A medical researcher might be interested in the rate at which the radius of an artery changes with the concentration of alcohol in the bloodstream.



A 1-unit increase in $x$ always produces an $m$-unit change in $y$.

▲ **Figure 2.1.8**

Our next objective is to define precisely what is meant by the "rate of change of $y$ with respect to $x$" when $y$ is a function of $x$. In the case where $y$ is a linear function of $x$, say $y = mx + b$, the slope $m$ is the natural measure of the rate of change of $y$ with respect to $x$. As illustrated in Figure 2.1.8, each 1-unit increase in $x$ anywhere along the line produces an $m$-unit change in $y$, so we see that $y$ changes at a constant rate with respect to $x$ along the line and that $m$ measures this rate of change.

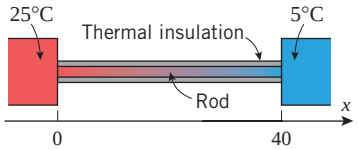
▶ **Example 7** Find the rate of change of $y$ with respect to $x$ if

(a) $y = 2x - 1$ (b) $y = -5x + 1$

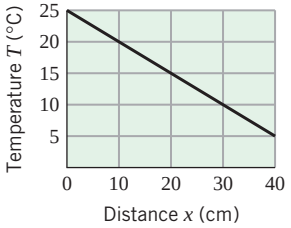
***Solution.*** In part (a) the rate of change of $y$ with respect to $x$ is $m = 2$, so each 1-unit increase in $x$ produces a 2-unit increase in $y$. In part (b) the rate of change of $y$ with respect to $x$ is $m = -5$, so each 1-unit increase in $x$ produces a 5-unit decrease in $y$. ◀

In applied problems, changing the units of measurement can change the slope of a line, so it is essential to include the units when calculating the slope and describing rates of change. The following example illustrates this.

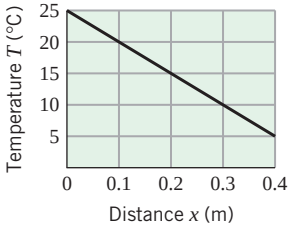
▶ **Example 8** Suppose that a uniform rod of length 40 cm (= 0.4 m) is thermally insulated around the lateral surface and that the exposed ends of the rod are held at constant temperatures of 25°C and 5°C, respectively (Figure 2.1.9*a*). It is shown in physics that under appropriate conditions the graph of the temperature $T$ versus the distance $x$ from the left-hand end of the rod will be a straight line. Parts (*b*) and (*c*) of Figure 2.1.9 show two



(a)

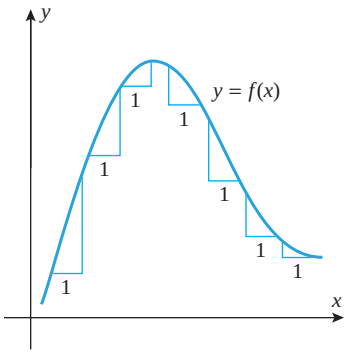


(b)



(c)

▲ **Figure 2.1.9**



▲ **Figure 2.1.10**

such graphs: one in which $x$ is measured in centimeters and one in which it is measured in meters. The slopes in the two cases are

$$m = \frac{5-25}{40-0} = \frac{-20}{40} = -0.5 \tag{6}$$

$$m = \frac{5-25}{0.4-0} = \frac{-20}{0.4} = -50 \tag{7}$$

The slope in (6) implies that the temperature *decreases* at a rate of 0.5°C per centimeter of distance from the left end of the rod, and the slope in (7) implies that the temperature decreases at a rate of 50°C per meter of distance from the left end of the rod. The two statements are equivalent physically, even though the slopes differ. ◀

Although the rate of change of $y$ with respect to $x$ is constant along a nonvertical line $y = mx + b$, this is not true for a general curve $y = f(x)$. For example, in Figure 2.1.10 the change in $y$ that results from a 1-unit increase in $x$ tends to have greater magnitude in regions where the curve rises or falls rapidly than in regions where it rises or falls slowly. As with velocity, we will distinguish between the average rate of change over an interval and the instantaneous rate of change at a specific point.

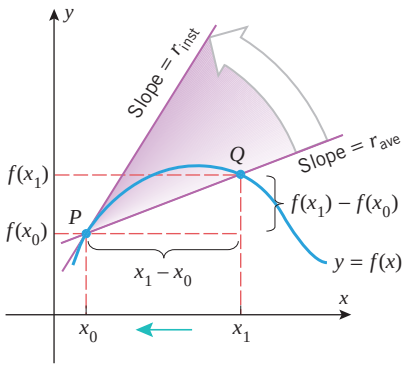
If $y = f(x)$, then we define the ***average rate of change of y with respect to x over the interval*** $[x_0, x_1]$ to be

$$r_{\text{ave}} = \frac{f(x_1) - f(x_0)}{x_1 - x_0} \tag{8}$$

and we define the ***instantaneous rate of change of y with respect to x at*** $x_0$ to be

$$r_{\text{inst}} = \lim_{x_1 \to x_0} \frac{f(x_1) - f(x_0)}{x_1 - x_0} \tag{9}$$

Geometrically, the average rate of change of $y$ with respect to $x$ over the interval $[x_0, x_1]$ is the slope of the secant line through the points $P(x_0, f(x_0))$ and $Q(x_1, f(x_1))$ (Figure 2.1.11), and the instantaneous rate of change of $y$ with respect to $x$ at $x_0$ is the slope of the tangent line at the point $P(x_0, f(x_0))$ (since it is the limit of the slopes of the secant lines through $P$).



▶ **Figure 2.1.11**

If desired, we can let $h = x_1 - x_0$, and rewrite (8) and (9) as

$$r_{\text{ave}} = \frac{f(x_0 + h) - f(x_0)}{h} \tag{10}$$

$$r_{\text{inst}} = \lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h} \tag{11}$$

**▶ Example 9** Let $y = x^2 + 1$.

(a) Find the average rate of change of $y$ with respect to $x$ over the interval $[3, 5]$.

(b) Find the instantaneous rate of change of $y$ with respect to $x$ when $x = -4$.

***Solution (a).*** We will apply Formula (8) with $f(x) = x^2 + 1$, $x_0 = 3$, and $x_1 = 5$. This yields

$$r_{\text{ave}} = \frac{f(x_1) - f(x_0)}{x_1 - x_0} = \frac{f(5) - f(3)}{5 - 3} = \frac{26 - 10}{2} = 8$$

Thus, $y$ increases an average of 8 units per unit increase in $x$ over the interval $[3, 5]$.

***Solution (b).*** We will apply Formula (9) with $f(x) = x^2 + 1$ and $x_0 = -4$. This yields

$$r_{\text{inst}} = \lim_{x_1 \to x_0} \frac{f(x_1) - f(x_0)}{x_1 - x_0} = \lim_{x_1 \to -4} \frac{f(x_1) - f(-4)}{x_1 - (-4)} = \lim_{x_1 \to -4} \frac{(x_1^2 + 1) - 17}{x_1 + 4}$$

$$= \lim_{x_1 \to -4} \frac{x_1^2 - 16}{x_1 + 4} = \lim_{x_1 \to -4} \frac{(x_1 + 4)(x_1 - 4)}{x_1 + 4} = \lim_{x_1 \to -4} (x_1 - 4) = -8$$

Thus, a small increase in $x$ from $x = -4$ will produce approximately an 8-fold decrease in $y$. ◀

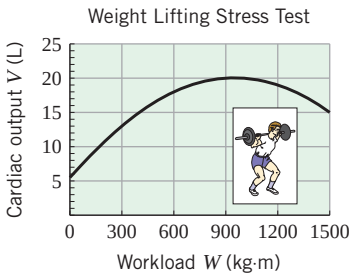
Perform the calculations in Example 9 using Formulas (10) and (11).

## RATES OF CHANGE IN APPLICATIONS

In applied problems, average and instantaneous rates of change must be accompanied by appropriate units. In general, the units for a rate of change of $y$ with respect to $x$ are obtained by "dividing" the units of $y$ by the units of $x$ and then simplifying according to the standard rules of algebra. Here are some examples:

- If $y$ is in degrees Fahrenheit (°F) and $x$ is in inches (in), then a rate of change of $y$ with respect to $x$ has units of degrees Fahrenheit per inch (°F/in).
- If $y$ is in feet per second (ft/s) and $x$ is in seconds (s), then a rate of change of $y$ with respect to $x$ has units of feet per second per second (ft/s/s), which would usually be written as ft/s$^2$.
- If $y$ is in newton-meters (N·m) and $x$ is in meters (m), then a rate of change of $y$ with respect to $x$ has units of newtons (N), since N·m/m = N.
- If $y$ is in foot-pounds (ft·lb) and $x$ is in hours (h), then a rate of change of $y$ with respect to $x$ has units of foot-pounds per hour (ft·lb/h).

**▶ Example 10** The limiting factor in athletic endurance is cardiac output, that is, the volume of blood that the heart can pump per unit of time during an athletic competition. Figure 2.1.12 shows a stress-test graph of cardiac output $V$ in liters (L) of blood versus workload $W$ in kilogram-meters (kg·m) for 1 minute of weight lifting. This graph illustrates the known medical fact that cardiac output increases with the workload, but after reaching a peak value begins to decrease.



▲ Figure 2.1.12

(a) Use the secant line shown in Figure 2.1.13*a* to estimate the average rate of change of cardiac output with respect to workload as the workload increases from 300 to 1200 kg·m.

(b) Use the line segment shown in Figure 2.1.13*b* to estimate the instantaneous rate of change of cardiac output with respect to workload at the point where the workload is 300 kg·m.

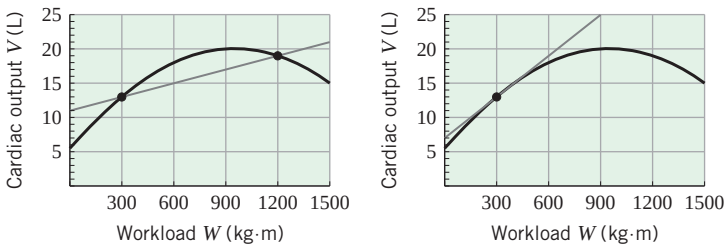
***Solution (a).*** Using the estimated points (300, 13) and (1200, 19) to find the slope of the secant line, we obtain

$$r_{\text{ave}} \approx \frac{19-13}{1200-300} \approx 0.0067 \frac{\text{L}}{\text{kg·m}}$$

This means that on average a 1-unit increase in workload produced a 0.0067 L increase in cardiac output over the interval.

***Solution (b).*** We estimate the slope of the cardiac output curve at $W = 300$ by sketching a line that appears to meet the curve at $W = 300$ with slope equal to that of the curve (Figure 2.1.13*b*). Estimating points (0, 7) and (900, 25) on this line, we obtain

$$r_{\text{inst}} \approx \frac{25-7}{900-0} = 0.02 \frac{\text{L}}{\text{kg·m}} \quad \blacktriangleleft$$



▶ **Figure 2.1.13**

## ✔ QUICK CHECK EXERCISES 2.1 (See page 143 for answers.)

**1.** The slope $m_{\tan}$ of the tangent line to the curve $y = f(x)$ at the point $P(x_0, f(x_0))$ is given by

$$m_{\tan} = \lim_{x \to x_0} _____ = \lim_{h \to 0} _____$$

**2.** The tangent line to the curve $y = (x-1)^2$ at the point $(-1, 4)$ has equation $4x + y = 0$. Thus, the value of the limit

$$\lim_{x \to -1} \frac{x^2 - 2x - 3}{x + 1}$$

is _____.

**3.** A particle is moving along an $s$-axis, where $s$ is in feet. During the first 5 seconds of motion, the position of the particle is given by

$$s = 10 - (3-t)^2, \quad 0 \le t \le 5$$

Use this position function to complete each part.

(a) Initially, the particle moves a distance of _____ ft in the (positive/negative) _____ direction; then it reverses direction, traveling a distance of _____ ft during the remainder of the 5-second period.

(b) The average velocity of the particle over the 5-second period is _____.

**4.** Let $s = f(t)$ be the equation of a position versus time curve for a particle in rectilinear motion, where $s$ is in meters and $t$ is in seconds. Assume that $s = -1$ when $t = 2$ and that the instantaneous velocity of the particle at this instant is 3 m/s. The equation of the tangent line to the position versus time curve at time $t = 2$ is _____.

**5.** Suppose that $y = x^2 + x$.

(a) The average rate of change of $y$ with respect to $x$ over the interval $2 \le x \le 5$ is _____.

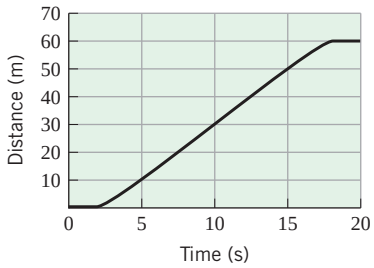
(b) The instantaneous rate of change of $y$ with respect to $x$ at $x = 2$, $r_{\text{inst}}$, is given by the limit _____.

## EXERCISE SET 2.1

**1.** The accompanying figure on the next page shows the position versus time curve for an elevator that moves upward a distance of 60 m and then discharges its passengers.

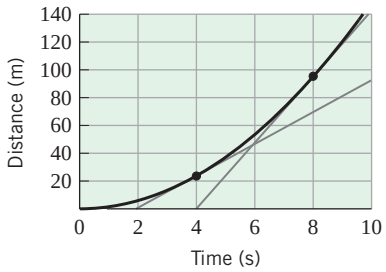
(a) Estimate the instantaneous velocity of the elevator at $t = 10$ s.

(b) Sketch a velocity versus time curve for the motion of the elevator for $0 \le t \le 20$.



◀ **Figure Ex-1**

**2.** The accompanying figure shows the position versus time curve for an automobile over a period of time of 10 s. Use the line segments shown in the figure to estimate the instantaneous velocity of the automobile at time $t = 4$ s and again at time $t = 8$ s.



◀ **Figure Ex-2**

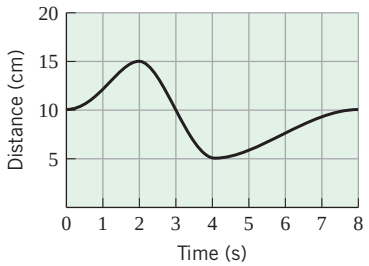
**3.** The accompanying figure shows the position versus time curve for a certain particle moving along a straight line. Estimate each of the following from the graph:

(a) the average velocity over the interval $0 \le t \le 3$

(b) the values of $t$ at which the instantaneous velocity is zero

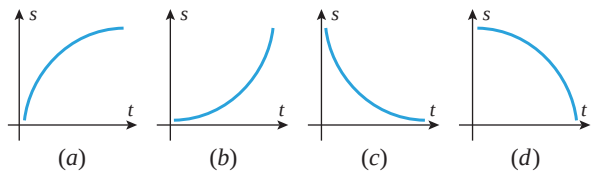
(c) the values of $t$ at which the instantaneous velocity is either a maximum or a minimum

(d) the instantaneous velocity when $t = 3$ s.



◀ **Figure Ex-3**

**4.** The accompanying figure shows the position versus time curves of four different particles moving on a straight line. For each particle, determine whether its instantaneous velocity is increasing or decreasing with time.



▲ **Figure Ex-4**

**FOCUS ON CONCEPTS**

**5.** If a particle moves at constant velocity, what can you say about its position versus time curve?

**6.** An automobile, initially at rest, begins to move along a straight track. The velocity increases steadily until suddenly the driver sees a concrete barrier in the road and applies the brakes sharply at time $t_0$. The car decelerates rapidly, but it is too late—the car crashes into the barrier at time $t_1$ and instantaneously comes to rest. Sketch a position versus time curve that might represent the motion of the car. Indicate how characteristics of your curve correspond to the events of this scenario.

**7–10** For each exercise, sketch a curve and a line $L$ satisfying the stated conditions. ■

**7.** $L$ is tangent to the curve and intersects the curve in at least two points.

**8.** $L$ intersects the curve in exactly one point, but $L$ is not tangent to the curve.

**9.** $L$ is tangent to the curve at two different points.

**10.** $L$ is tangent to the curve at two different points and intersects the curve at a third point.

**11–14** A function $y = f(x)$ and values of $x_0$ and $x_1$ are given.

(a) Find the average rate of change of $y$ with respect to $x$ over the interval $[x_0, x_1]$.

(b) Find the instantaneous rate of change of $y$ with respect to $x$ at the specified value of $x_0$.

(c) Find the instantaneous rate of change of $y$ with respect to $x$ at an arbitrary value of $x_0$.

(d) The average rate of change in part (a) is the slope of a certain secant line, and the instantaneous rate of change in part (b) is the slope of a certain tangent line. Sketch the graph of $y = f(x)$ together with those two lines. ■

**11.** $y = 2x^2;\ x_0 = 0,\ x_1 = 1$ **12.** $y = x^3;\ x_0 = 1,\ x_1 = 2$

**13.** $y = 1/x;\ x_0 = 2,\ x_1 = 3$ **14.** $y = 1/x^2;\ x_0 = 1,\ x_1 = 2$

**15–18** A function $y = f(x)$ and an $x$-value $x_0$ are given.

(a) Find a formula for the slope of the tangent line to the graph of $f$ at a general point $x = x_0$.

(b) Use the formula obtained in part (a) to find the slope of the tangent line for the given value of $x_0$. ■

**15.** $f(x) = x^2 - 1;\ x_0 = -1$

**16.** $f(x) = x^2 + 3x + 2;\ x_0 = 2$

**17.** $f(x) = x + \sqrt{x};\ x_0 = 1$

**18.** $f(x) = 1/\sqrt{x};\ x_0 = 4$

**19–22 True–False** Determine whether the statement is true or false. Explain your answer. ■

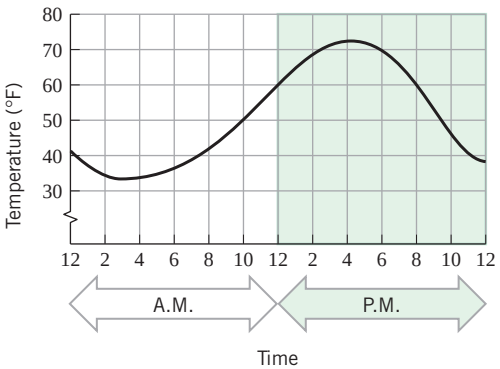
**19.** If $\lim_{x \to 1} \dfrac{f(x) - f(1)}{x - 1} = 3$, then $\lim_{h \to 0} \dfrac{f(1+h) - f(1)}{h} = 3$.

**20.** A tangent line to a curve $y = f(x)$ is a particular kind of secant line to the curve.

**21.** The velocity of an object represents a change in the object's position.

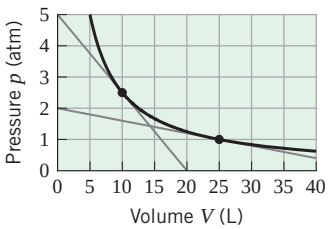
**22.** A 50-foot horizontal metal beam is supported on either end by concrete pillars and a weight is placed on the middle of the beam. If $f(x)$ models how many inches the center of the beam sags when the weight measures $x$ tons, then the units of the rate of change of $y = f(x)$ with respect to $x$ are inches/ton.

**23.** Suppose that the outside temperature versus time curve over a 24-hour period is as shown in the accompanying figure.
(a) Estimate the maximum temperature and the time at which it occurs.
(b) The temperature rise is fairly linear from 8 A.M. to 2 P.M. Estimate the rate at which the temperature is increasing during this time period.
(c) Estimate the time at which the temperature is decreasing most rapidly. Estimate the instantaneous rate of change of temperature with respect to time at this instant.



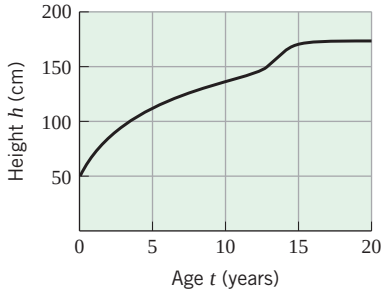
▲ **Figure Ex-23**

**24.** The accompanying figure shows the graph of the pressure $p$ in atmospheres (atm) versus the volume $V$ in liters (L) of 1 mole of an ideal gas at a constant temperature of 300 K (kelvins). Use the line segments shown in the figure to estimate the rate of change of pressure with respect to volume at the points where $V = 10$ L and $V = 25$ L.



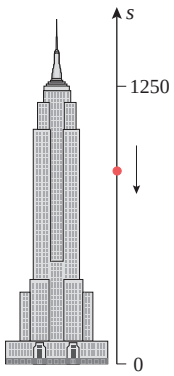
◀ **Figure Ex-24**

**25.** The accompanying figure shows the graph of the height $h$ in centimeters versus the age $t$ in years of an individual from birth to age 20.
(a) When is the growth rate greatest?
(b) Estimate the growth rate at age 5.
(c) At approximately what age between 10 and 20 is the growth rate greatest? Estimate the growth rate at this age.
(d) Draw a rough graph of the growth rate versus age.



◀ **Figure Ex-25**

**26.** An object is released from rest (its initial velocity is zero) from the Empire State Building at a height of 1250 ft above street level (Figure Ex-26). The height of the object can be modeled by the position function $s = f(t) = 1250 - 16t^2$.
(a) Verify that the object is still falling at $t = 5$ s.
(b) Find the average velocity of the object over the time interval from $t = 5$ to $t = 6$ s.
(c) Find the object's instantaneous velocity at time $t = 5$ s.



◀ **Figure Ex-26**

**27.** During the first 40 s of a rocket flight, the rocket is propelled straight up so that in $t$ seconds it reaches a height of $s = 0.3t^3$ ft.
(a) How high does the rocket travel in 40 s?
(b) What is the average velocity of the rocket during the first 40 s?
(c) What is the average velocity of the rocket during the first 1000 ft of its flight?
(d) What is the instantaneous velocity of the rocket at the end of 40 s?

**28.** An automobile is driven down a straight highway such that after $0 \le t \le 12$ seconds it is $s = 4.5t^2$ feet from its initial position. *(cont.)*

(a) Find the average velocity of the car over the interval [0, 12].
(b) Find the instantaneous velocity of the car at $t = 6$.

**29.** A robot moves in the positive direction along a straight line so that after $t$ minutes its distance is $s = 6t^4$ feet from the origin.
(a) Find the average velocity of the robot over the interval [2, 4].
(b) Find the instantaneous velocity at $t = 2$.

**30. Writing** Discuss how the tangent line to the graph of a function $y = f(x)$ at a point $P(x_0, f(x_0))$ is defined in terms of secant lines to the graph through point $P$.

**31. Writing** A particle is in rectilinear motion during the time interval $0 \le t \le 2$. Explain the connection between the instantaneous velocity of the particle at time $t = 1$ and the average velocities of the particle during portions of the interval $0 \le t \le 2$.

## ✔ QUICK CHECK ANSWERS 2.1

**1.** $\dfrac{f(x) - f(x_0)}{x - x_0}$; $\dfrac{f(x_0 + h) - f(x_0)}{h}$ **2.** $-4$ **3.** (a) 9; positive; 4 (b) 1 ft/s **4.** $s = 3t - 7$

**5.** (a) 8 (b) $\lim\limits_{x \to 2} \dfrac{(x^2 + x) - 6}{x - 2}$ or $\lim\limits_{h \to 0} \dfrac{[(2 + h)^2 + (2 + h)] - 6}{h}$

# 2.2 THE DERIVATIVE FUNCTION

*In this section we will discuss the concept of a "derivative," which is the primary mathematical tool that is used to calculate and study rates of change.*

## DEFINITION OF THE DERIVATIVE FUNCTION

In the last section we showed that if the limit

$$\lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h}$$

exists, then it can be interpreted either as the slope of the tangent line to the curve $y = f(x)$ at $x = x_0$ or as the instantaneous rate of change of $y$ with respect to $x$ at $x = x_0$ [see Formulas (2) and (11) of that section]. This limit is so important that it has a special notation:

$$f'(x_0) = \lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h} \tag{1}$$

You can think of $f'$ (read "$f$ prime") as a function whose input is $x_0$ and whose output is the number $f'(x_0)$ that represents either the slope of the tangent line to $y = f(x)$ at $x = x_0$ or the instantaneous rate of change of $y$ with respect to $x$ at $x = x_0$. To emphasize this function point of view, we will replace $x_0$ by $x$ in (1) and make the following definition.

The expression

$$\frac{f(x + h) - f(x)}{h}$$

that appears in (2) is commonly called the ***difference quotient***.

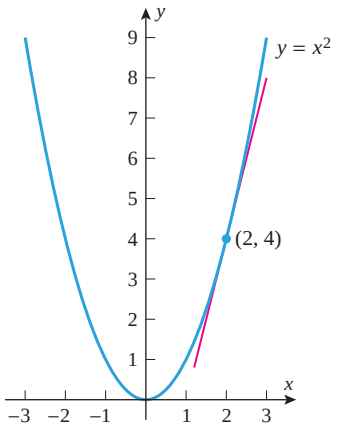
**2.2.1 DEFINITION** The function $f'$ defined by the formula

$$f'(x) = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h} \tag{2}$$

is called the ***derivative of f with respect to x***. The domain of $f'$ consists of all $x$ in the domain of $f$ for which the limit exists.

The term "derivative" is used because the function $f'$ is *derived* from the function $f$ by a limiting process.

▶ **Example 1** Find the derivative with respect to $x$ of $f(x) = x^2$, and use it to find the equation of the tangent line to $y = x^2$ at $x = 2$.



▲ Figure 2.2.1

***Solution.*** It follows from (2) that

$$f'(x) = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h} = \lim_{h\to 0} \frac{(x+h)^2 - x^2}{h}$$

$$= \lim_{h\to 0} \frac{x^2 + 2xh + h^2 - x^2}{h} = \lim_{h\to 0} \frac{2xh + h^2}{h}$$

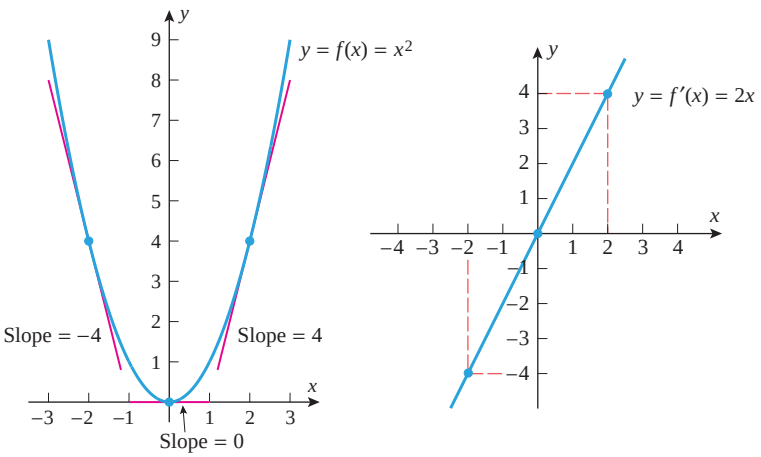
$$= \lim_{h\to 0} (2x + h) = 2x$$

Thus, the slope of the tangent line to $y = x^2$ at $x = 2$ is $f'(2) = 4$. Since $y = 4$ if $x = 2$, the point-slope form of the tangent line is

$$y - 4 = 4(x - 2)$$

which we can rewrite in slope-intercept form as $y = 4x - 4$ (Figure 2.2.1). ◀

You can think of $f'$ as a "slope-producing function" in the sense that the value of $f'(x)$ at $x = x_0$ is the slope of the tangent line to the graph of $f$ at $x = x_0$. This aspect of the derivative is illustrated in Figure 2.2.2, which shows the graphs of $f(x) = x^2$ and its derivative $f'(x) = 2x$ (obtained in Example 1). The figure illustrates that the values of $f'(x) = 2x$ at $x = -2, 0$, and 2 correspond to the slopes of the tangent lines to the graph of $f(x) = x^2$ at those values of $x$.



▶ Figure 2.2.2

In general, if $f'(x)$ is defined at $x = x_0$, then the point-slope form of the equation of the tangent line to the graph of $y = f(x)$ at $x = x_0$ may be found using the following steps.

***Finding an Equation for the Tangent Line to $y = f(x)$ at $x = x_0$.***

**Step 1.** Evaluate $f(x_0)$; the point of tangency is $(x_0, f(x_0))$.

**Step 2.** Find $f'(x)$ and evaluate $f'(x_0)$, which is the slope $m$ of the line.

**Step 3.** Substitute the value of the slope $m$ and the point $(x_0, f(x_0))$ into the point-slope form of the line

$$y - f(x_0) = f'(x_0)(x - x_0)$$

or, equivalently,

$$y = f(x_0) + f'(x_0)(x - x_0) \tag{3}$$

### ▶ Example 2

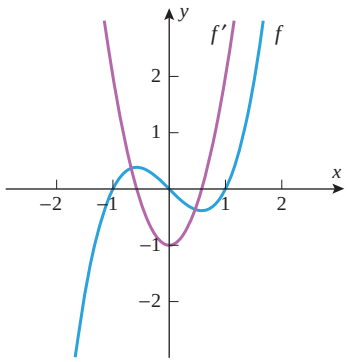
(a) Find the derivative with respect to $x$ of $f(x) = x^3 - x$.

(b) Graph $f$ and $f'$ together, and discuss the relationship between the two graphs.

In Solution (a), the binomial formula is used to expand $(x+h)^3$. This formula may be found on the front endpaper.

***Solution (a).***

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{f(x+h) - f(x)}{h} \\ &= \lim_{h\to 0} \frac{[(x+h)^3 - (x+h)] - [x^3 - x]}{h} \\ &= \lim_{h\to 0} \frac{[x^3 + 3x^2h + 3xh^2 + h^3 - x - h] - [x^3 - x]}{h} \\ &= \lim_{h\to 0} \frac{3x^2h + 3xh^2 + h^3 - h}{h} \\ &= \lim_{h\to 0} [3x^2 + 3xh + h^2 - 1] = 3x^2 - 1 \end{aligned}$$



▲ Figure 2.2.3

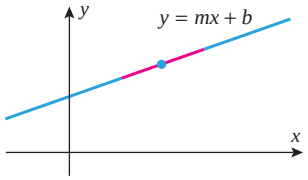
***Solution (b).*** Since $f'(x)$ can be interpreted as the slope of the tangent line to the graph of $y = f(x)$ at $x$, it follows that $f'(x)$ is positive where the tangent line has positive slope, is negative where the tangent line has negative slope, and is zero where the tangent line is horizontal. We leave it for you to verify that this is consistent with the graphs of $f(x) = x^3 - x$ and $f'(x) = 3x^2 - 1$ shown in Figure 2.2.3. ◀

### ▶ Example 3

At each value of $x$, the tangent line to a line $y = mx + b$ coincides with the line itself (Figure 2.2.4), and hence all tangent lines have slope $m$. This suggests geometrically that if $f(x) = mx + b$, then $f'(x) = m$ for all $x$. This is confirmed by the following computations:

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{f(x+h) - f(x)}{h} \\ &= \lim_{h\to 0} \frac{[m(x+h) + b] - [mx + b]}{h} \\ &= \lim_{h\to 0} \frac{mh}{h} = \lim_{h\to 0} m = m \end{aligned}$$

◀



At each value of $x$ the tangent line has slope $m$.

▲ Figure 2.2.4

The result in Example 3 is consistent with our earlier observation that the rate of change of $y$ with respect to $x$ along a line $y = mx + b$ is constant and that constant is $m$.

### ▶ Example 4

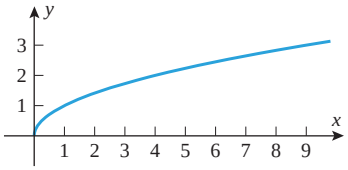
(a) Find the derivative with respect to $x$ of $f(x) = \sqrt{x}$.

(b) Find the slope of the tangent line to $y = \sqrt{x}$ at $x = 9$.

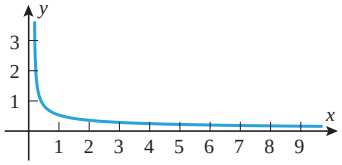
(c) Find the limits of $f'(x)$ as $x \to 0^+$ and as $x \to +\infty$, and explain what those limits say about the graph of $f$.

***Solution (a).*** Recall from Example 4 of Section 2.1 that the slope of the tangent line to $y = \sqrt{x}$ at $x = x_0$ is given by $m_{\text{tan}} = 1/(2\sqrt{x_0})$. Thus, $f'(x) = 1/(2\sqrt{x})$.

***Solution (b).*** The slope of the tangent line at $x = 9$ is $f'(9)$. From part (a), this slope is $f'(9) = 1/(2\sqrt{9}) = \frac{1}{6}$.



$y = f(x) = \sqrt{x}$



$y = f'(x) = \dfrac{1}{2\sqrt{x}}$

▲ **Figure 2.2.5**

***Solution (c).*** The graphs of $f(x) = \sqrt{x}$ and $f'(x) = 1/(2\sqrt{x})$ are shown in Figure 2.2.5. Observe that $f'(x) > 0$ if $x > 0$, which means that all tangent lines to the graph of $y = \sqrt{x}$ have positive slope at all points in this interval. Since

$$\lim_{x \to 0^+} \frac{1}{2\sqrt{x}} = +\infty \quad \text{and} \quad \lim_{x \to +\infty} \frac{1}{2\sqrt{x}} = 0$$

the graph of $f$ becomes more and more vertical as $x \to 0^+$ and more and more horizontal as $x \to +\infty$. ◀

## COMPUTING INSTANTANEOUS VELOCITY

It follows from Formula (5) of Section 2.1 (with $t$ replacing $t_0$) that if $s = f(t)$ is the position function of a particle in rectilinear motion, then the instantaneous velocity at an arbitrary time $t$ is given by

$$v_{\text{inst}} = \lim_{h \to 0} \frac{f(t+h) - f(t)}{h}$$

Since the right side of this equation is the derivative of the function $f$ (with $t$ rather than $x$ as the independent variable), it follows that if $f(t)$ is the position function of a particle in rectilinear motion, then the function

$$v(t) = f'(t) = \lim_{h \to 0} \frac{f(t+h) - f(t)}{h} \tag{4}$$

represents the instantaneous velocity of the particle at time $t$. Accordingly, we call (4) the ***instantaneous velocity function*** or, more simply, the ***velocity function*** of the particle.

▶ **Example 5** Recall the particle from Example 5 of Section 2.1 with position function $s = f(t) = 1 + 5t - 2t^2$. Here $f(t)$ is measured in meters and $t$ is measured in seconds. Find the velocity function of the particle.

***Solution.*** It follows from (4) that the velocity function is

$$\begin{aligned} v(t) &= \lim_{h \to 0} \frac{f(t+h) - f(t)}{h} = \lim_{h \to 0} \frac{[1 + 5(t+h) - 2(t+h)^2] - [1 + 5t - 2t^2]}{h} \\ &= \lim_{h \to 0} \frac{-2[t^2 + 2th + h^2 - t^2] + 5h}{h} = \lim_{h \to 0} \frac{-4th - 2h^2 + 5h}{h} \\ &= \lim_{h \to 0} (-4t - 2h + 5) = 5 - 4t \end{aligned}$$

where the units of velocity are meters per second. ◀

## DIFFERENTIABILITY

It is possible that the limit that defines the derivative of a function $f$ may not exist at certain points in the domain of $f$. At such points the derivative is undefined. To account for this possibility we make the following definition.

**2.2.2 DEFINITION** A function $f$ is said to be ***differentiable at $x_0$*** if the limit

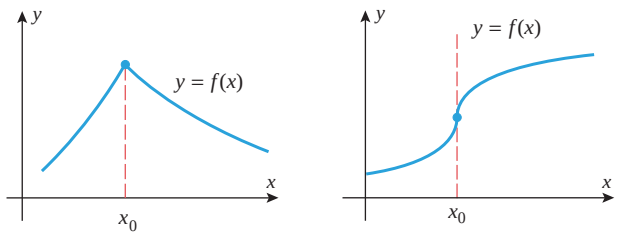
$$f'(x_0) = \lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h} \tag{5}$$

exists. If $f$ is differentiable at each point of the open interval $(a, b)$, then we say that it is ***differentiable on $(a, b)$***, and similarly for open intervals of the form $(a, +\infty)$, $(-\infty, b)$, and $(-\infty, +\infty)$. In the last case we say that $f$ is ***differentiable everywhere***.

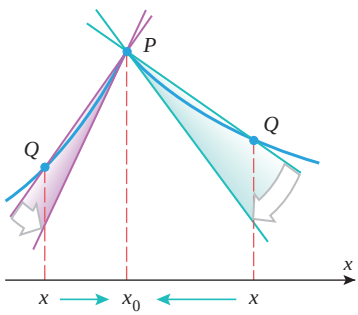
Geometrically, a function $f$ is differentiable at $x_0$ if the graph of $f$ has a tangent line at $x_0$. Thus, $f$ is not differentiable at any point $x_0$ where the secant lines from $P(x_0, f(x_0))$ to points $Q(x, f(x))$ distinct from $P$ do not approach a unique *nonvertical* limiting position as $x \to x_0$. Figure 2.2.6 illustrates two common ways in which a function that is continuous at $x_0$ can fail to be differentiable at $x_0$. These can be described informally as

- corner points
- points of vertical tangency

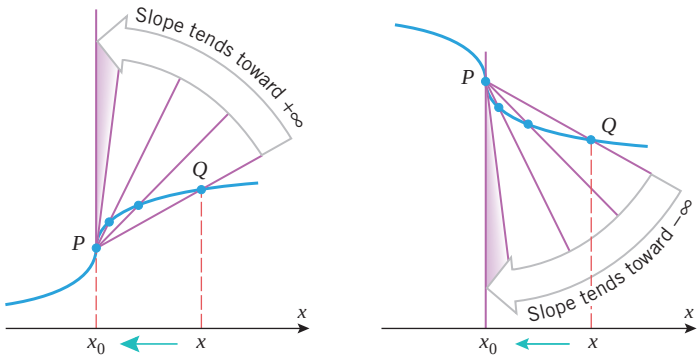
At a corner point, the slopes of the secant lines have different limits from the left and from the right, and hence the *two-sided* limit that defines the derivative does not exist (Figure 2.2.7). At a point of vertical tangency the slopes of the secant lines approach $+\infty$ or $-\infty$ from the left and from the right (Figure 2.2.8), so again the limit that defines the derivative does not exist.



▶ **Figure 2.2.6**



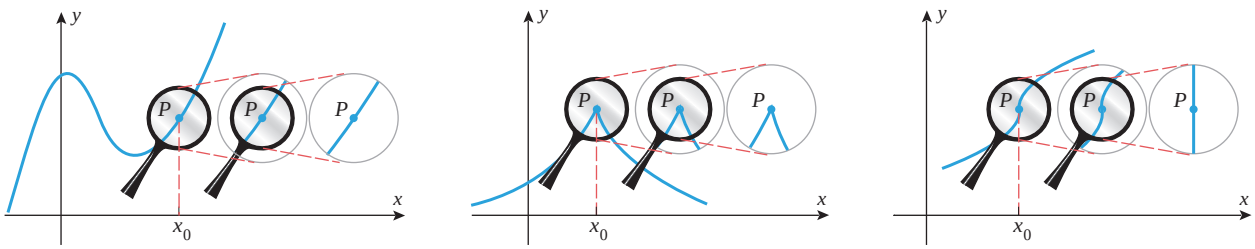
▲ **Figure 2.2.7**



▲ **Figure 2.2.8**

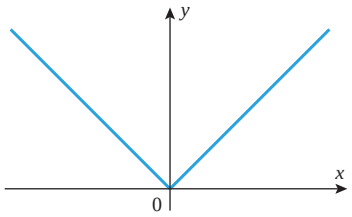
There are other less obvious circumstances under which a function may fail to be differentiable. (See Exercise 49, for example.)

Differentiability at $x_0$ can also be described informally in terms of the behavior of the graph of $f$ under increasingly stronger magnification at the point $P(x_0, f(x_0))$ (Figure 2.2.9). If $f$ is differentiable at $x_0$, then under sufficiently strong magnification at $P$ the



▲ **Figure 2.2.9**

graph looks like a nonvertical line (the tangent line); if a corner point occurs at $x_0$, then no matter how great the magnification at $P$ the corner persists and the graph never looks like a nonvertical line; and if vertical tangency occurs at $x_0$, then the graph of $f$ looks like a vertical line under sufficiently strong magnification at $P$.



▲ Figure 2.2.10

▶ **Example 6** The graph of $y = |x|$ in Figure 2.2.10 has a corner at $x = 0$, which implies that $f(x) = |x|$ is not differentiable at $x = 0$.

(a) Prove that $f(x) = |x|$ is not differentiable at $x = 0$ by showing that the limit in Definition 2.2.2 does not exist at $x = 0$.

(b) Find a formula for $f'(x)$.

***Solution (a).*** From Formula (5) with $x_0 = 0$, the value of $f'(0)$, if it were to exist, would be given by

$$f'(0) = \lim_{h \to 0} \frac{f(0+h) - f(0)}{h} = \lim_{h \to 0} \frac{f(h) - f(0)}{h} = \lim_{h \to 0} \frac{|h| - |0|}{h} = \lim_{h \to 0} \frac{|h|}{h} \tag{6}$$

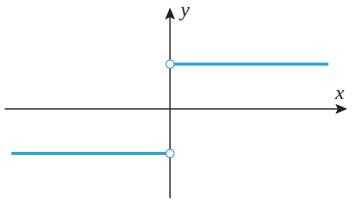
But

$$\frac{|h|}{h} = \begin{cases} 1, & h > 0 \\ -1, & h < 0 \end{cases}$$

so that

$$\lim_{h \to 0^-} \frac{|h|}{h} = -1 \quad \text{and} \quad \lim_{h \to 0^+} \frac{|h|}{h} = 1$$

Since these one-sided limits are not equal, the two-sided limit in (5) does not exist, and hence $f$ is not differentiable at $x = 0$.



▲ Figure 2.2.11

***Solution (b).*** A formula for the derivative of $f(x) = |x|$ can be obtained by writing $|x|$ in piecewise form and treating the cases $x > 0$ and $x < 0$ separately. If $x > 0$, then $f(x) = x$ and $f'(x) = 1$; if $x < 0$, then $f(x) = -x$ and $f'(x) = -1$. Thus,

$$f'(x) = \begin{cases} 1, & x > 0 \\ -1, & x < 0 \end{cases}$$

The graph of $f'$ is shown in Figure 2.2.11. Observe that $f'$ is not continuous at $x = 0$, so this example shows that a function that is continuous everywhere may have a derivative that fails to be continuous everywhere. ◀

## THE RELATIONSHIP BETWEEN DIFFERENTIABILITY AND CONTINUITY

We already know that functions are not differentiable at corner points and points of vertical tangency. The next theorem shows that functions are not differentiable at points of discontinuity. We will do this by proving that if $f$ is differentiable at a point, then it must be continuous at that point.

A theorem that says "If statement $A$ is true, then statement $B$ is true" is equivalent to the theorem that says "If statement $B$ is not true, then statement $A$ is not true." The two theorems are called ***contrapositive forms*** of one another. Thus, Theorem 2.2.3 can be rewritten in contrapositive form as "If a function $f$ is not continuous at $x_0$, then $f$ is not differentiable at $x_0$."

**2.2.3 THEOREM** *If a function $f$ is differentiable at $x_0$, then $f$ is continuous at $x_0$.*

**PROOF** We are given that $f$ is differentiable at $x_0$, so it follows from (5) that $f'(x_0)$ exists and is given by

$$f'(x_0) = \lim_{h \to 0} \left[ \frac{f(x_0+h) - f(x_0)}{h} \right] \tag{7}$$

To show that $f$ is continuous at $x_0$, we must show that $\lim_{x \to x_0} f(x) = f(x_0)$ or, equivalently,

$$\lim_{x \to x_0} [f(x) - f(x_0)] = 0$$

Expressing this in terms of the variable $h = x - x_0$, we must prove that

$$\lim_{h \to 0} [f(x_0 + h) - f(x_0)] = 0$$

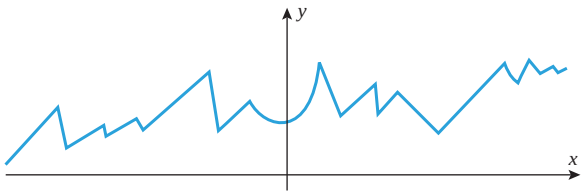
However, this can be proved using (7) as follows:

$$\begin{aligned} \lim_{h \to 0} [f(x_0 + h) - f(x_0)] &= \lim_{h \to 0} \left[ \frac{f(x_0 + h) - f(x_0)}{h} \cdot h \right] \\ &= \lim_{h \to 0} \left[ \frac{f(x_0 + h) - f(x_0)}{h} \right] \cdot \lim_{h \to 0} h \\ &= f'(x_0) \cdot 0 = 0 \quad \blacksquare \end{aligned}$$

**WARNING**

The converse of Theorem 2.2.3 is false; that is, *a function may be continuous at a point but not differentiable at that point.* This occurs, for example, at corner points of continuous functions. For instance, $f(x) = |x|$ is continuous at $x = 0$ but not differentiable there (Example 6).

The relationship between continuity and differentiability was of great historical significance in the development of calculus. In the early nineteenth century mathematicians believed that if a continuous function had many points of nondifferentiability, these points, like the tips of a sawblade, would have to be separated from one another and joined by smooth curve segments (Figure 2.2.12). This misconception was corrected by a series of discoveries beginning in 1834. In that year a Bohemian priest, philosopher, and mathematician named Bernhard Bolzano discovered a procedure for constructing a continuous function that is not differentiable at any point. Later, in 1860, the great German mathematician Karl Weierstrass (biography on p. 102) produced the first formula for such a function. The graphs of such functions are impossible to draw; it is as if the corners are so numerous that any segment of the curve, when suitably enlarged, reveals more corners. The discovery of these functions was important in that it made mathematicians distrustful of their geometric intuition and more reliant on precise mathematical proof. Recently, such functions have started to play a fundamental role in the study of geometric objects called ***fractals***. Fractals have revealed an order to natural phenomena that were previously dismissed as random and chaotic.



▶ **Figure 2.2.12**

**Bernhard Bolzano (1781–1848)** Bolzano, the son of an art dealer, was born in Prague, Bohemia (Czech Republic). He was educated at the University of Prague, and eventually won enough mathematical fame to be recommended for a mathematics chair there. However, Bolzano became an ordained Roman Catholic priest, and in 1805 he was appointed to a chair of Philosophy at the University of Prague. Bolzano was a man of great human compassion; he spoke out for educational reform, he voiced the right of individual conscience over government demands, and he lectured on the absurdity of war and militarism. His views so disenchanted Emperor Franz I of Austria that the emperor pressed the Archbishop of Prague to have Bolzano recant his statements. Bolzano refused and was then forced to retire in 1824 on a small pension. Bolzano's main contribution to mathematics was philosophical. His work helped convince mathematicians that sound mathematics must ultimately rest on rigorous proof rather than intuition. In addition to his work in mathematics, Bolzano investigated problems concerning space, force, and wave propagation.

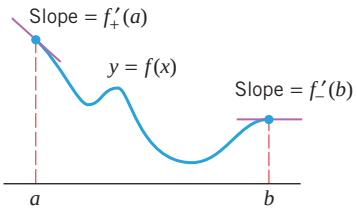
[*Image: http://en.wikipedia.org/wiki/File:Bernard_Bolzano.jpg*]

## DERIVATIVES AT THE ENDPOINTS OF AN INTERVAL

If a function $f$ is defined on a closed interval $[a, b]$ but not outside that interval, then $f'$ is not defined at the endpoints of the interval because derivatives are two-sided limits. To deal with this we define ***left-hand derivatives*** and ***right-hand derivatives*** by

$$f'_-(x) = \lim_{h \to 0^-} \frac{f(x+h) - f(x)}{h} \quad \text{and} \quad f'_+(x) = \lim_{h \to 0^+} \frac{f(x+h) - f(x)}{h}$$

respectively. These are called ***one-sided derivatives***. Geometrically, $f'_-(x)$ is the limit of the slopes of the secant lines as $x$ is approached from the left and $f'_+(x)$ is the limit of the slopes of the secant lines as $x$ is approached from the right. For a closed interval $[a, b]$, we will understand the derivative at the left endpoint to be $f'_+(a)$ and at the right endpoint to be $f'_-(b)$ (Figure 2.2.13).



▲ **Figure 2.2.13**

In general, we will say that $f$ is ***differentiable*** on an interval of the form $[a, b]$, $[a, +\infty)$, $(-\infty, b]$, $[a, b)$, or $(a, b]$ if it is differentiable at all points inside the interval and the appropriate one-sided derivative exists at each included endpoint.

It can be proved that a function $f$ is continuous from the left at those points where the left-hand derivative exists and is continuous from the right at those points where the right-hand derivative exists.

## OTHER DERIVATIVE NOTATIONS

The process of finding a derivative is called ***differentiation***. You can think of differentiation as an *operation* on functions that associates a function $f'$ with a function $f$. When the independent variable is $x$, the differentiation operation is also commonly denoted by

$$f'(x) = \frac{d}{dx}[f(x)] \quad \text{or} \quad f'(x) = D_x[f(x)]$$

In the case where there is a dependent variable $y = f(x)$, the derivative is also commonly denoted by

$$f'(x) = y'(x) \quad \text{or} \quad f'(x) = \frac{dy}{dx}$$

Later, the symbols $dy$ and $dx$ will be given specific meanings. However, for the time being do not regard $dy/dx$ as a ratio, but rather as a single symbol denoting the derivative.

With the above notations, the value of the derivative at a point $x_0$ can be expressed as

$$f'(x_0) = \frac{d}{dx}[f(x)]\bigg|_{x=x_0}, \quad f'(x_0) = D_x[f(x)]\big|_{x=x_0}, \quad f'(x_0) = y'(x_0), \quad f'(x_0) = \frac{dy}{dx}\bigg|_{x=x_0}$$

If a variable $w$ changes from some initial value $w_0$ to some final value $w_1$, then the final value minus the initial value is called an ***increment*** in $w$ and is denoted by

$$\Delta w = w_1 - w_0 \tag{8}$$

Increments can be positive or negative, depending on whether the final value is larger or smaller than the initial value. The increment symbol in (8) should not be interpreted as a product; rather, $\Delta w$ should be regarded as a single symbol representing the change in the value of $w$.

It is common to regard the variable $h$ in the derivative formula

$$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} \tag{9}$$

as an increment $\Delta x$ in $x$ and write (9) as

$$f'(x) = \lim_{\Delta x \to 0} \frac{f(x+\Delta x) - f(x)}{\Delta x} \tag{10}$$

Moreover, if $y = f(x)$, then the numerator in (10) can be regarded as the increment

$$\Delta y = f(x + \Delta x) - f(x) \tag{11}$$

in which case

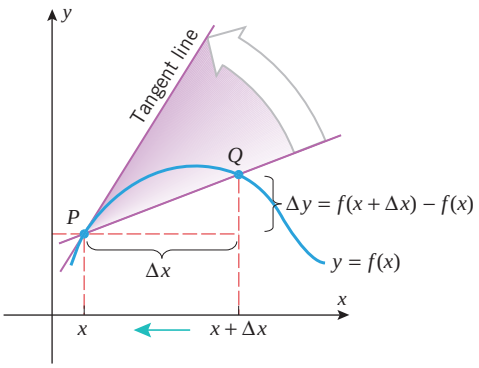
$$\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x} \tag{12}$$

The geometric interpretations of $\Delta x$ and $\Delta y$ are shown in Figure 2.2.14.

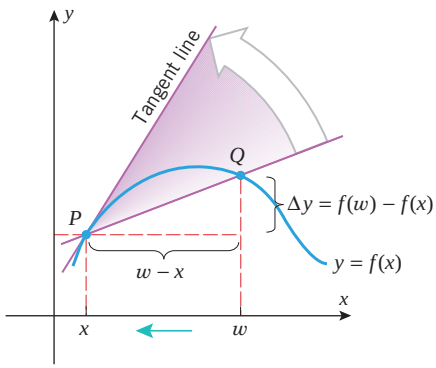
Sometimes it is desirable to express derivatives in a form that does not use increments at all. For example, if we let $w = x + h$ in Formula (9), then $w \to x$ as $h \to 0$, so we can rewrite that formula as

$$f'(x) = \lim_{w \to x} \frac{f(w) - f(x)}{w - x} \tag{13}$$

(Compare Figures 2.2.14 and 2.2.15.)



▲ **Figure 2.2.14**



▲ **Figure 2.2.15**

When letters other than $x$ and $y$ are used for the independent and dependent variables, the derivative notations must be adjusted accordingly. Thus, for example, if $s = f(t)$ is the position function for a particle in rectilinear motion, then the velocity function $v(t)$ in (4) can be expressed as

$$v(t) = \frac{ds}{dt} = \lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t} = \lim_{\Delta t \to 0} \frac{f(t + \Delta t) - f(t)}{\Delta t} \tag{14}$$

## ✔ QUICK CHECK EXERCISES 2.2 (See page 155 for answers.)

**1.** The function $f'(x)$ is defined by the formula

$$f'(x) = \lim_{h \to 0} _____$$

**2.** (a) The derivative of $f(x) = x^2$ is $f'(x) =$ _____.
(b) The derivative of $f(x) = \sqrt{x}$ is $f'(x) =$ _____.

**3.** Suppose that the line $2x + 3y = 5$ is tangent to the graph of $y = f(x)$ at $x = 1$. The value of $f(1)$ is _____ and the value of $f'(1)$ is _____.

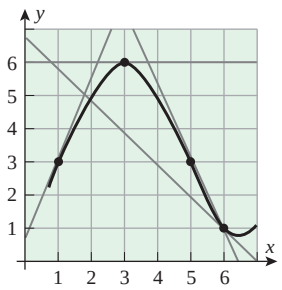
**4.** Which theorem guarantees us that if

$$\lim_{h \to 0} \frac{f(x_0 + h) - f(x_0)}{h}$$

exists, then $\lim_{x \to x_0} f(x) = f(x_0)$?

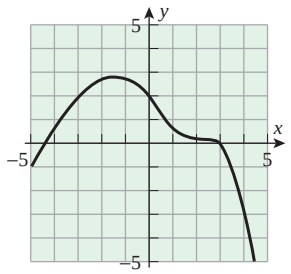
## EXERCISE SET 2.2 Graphing Utility

**1.** Use the graph of $y = f(x)$ in the accompanying figure to estimate the value of $f'(1)$, $f'(3)$, $f'(5)$, and $f'(6)$.



◀ **Figure Ex-1**

**2.** For the function graphed in the accompanying figure, arrange the numbers 0, $f'(-3)$, $f'(0)$, $f'(2)$, and $f'(4)$ in increasing order.



◀ **Figure Ex-2**

### FOCUS ON CONCEPTS

**3.** (a) If you are given an equation for the tangent line at the point $(a, f(a))$ on a curve $y = f(x)$, how would you go about finding $f'(a)$?

(b) Given that the tangent line to the graph of $y = f(x)$ at the point $(2, 5)$ has the equation $y = 3x - 1$, find $f'(2)$.

(c) For the function $y = f(x)$ in part (b), what is the instantaneous rate of change of $y$ with respect to $x$ at $x = 2$?

**4.** Given that the tangent line to $y = f(x)$ at the point $(1, 2)$ passes through the point $(-1, -1)$, find $f'(1)$.

**5.** Sketch the graph of a function $f$ for which $f(0) = -1$, $f'(0) = 0$, $f'(x) < 0$ if $x < 0$, and $f'(x) > 0$ if $x > 0$.

**6.** Sketch the graph of a function $f$ for which $f(0) = 0$, $f'(0) = 0$, and $f'(x) > 0$ if $x < 0$ or $x > 0$.

**7.** Given that $f(3) = -1$ and $f'(3) = 5$, find an equation for the tangent line to the graph of $y = f(x)$ at $x = 3$.

**8.** Given that $f(-2) = 3$ and $f'(-2) = -4$, find an equation for the tangent line to the graph of $y = f(x)$ at $x = -2$.

**9–14** Use Definition 2.2.1 to find $f'(x)$, and then find the tangent line to the graph of $y = f(x)$ at $x = a$. ■

**9.** $f(x) = 2x^2;\ a = 1$

**10.** $f(x) = 1/x^2;\ a = -1$

**11.** $f(x) = x^3;\ a = 0$

**12.** $f(x) = 2x^3 + 1;\ a = -1$

**13.** $f(x) = \sqrt{x+1};\ a = 8$

**14.** $f(x) = \sqrt{2x+1};\ a = 4$

**15–20** Use Formula (12) to find $dy/dx$. ■

**15.** $y = \dfrac{1}{x}$

**16.** $y = \dfrac{1}{x+1}$

**17.** $y = x^2 - x$

**18.** $y = x^4$

**19.** $y = \dfrac{1}{\sqrt{x}}$

**20.** $y = \dfrac{1}{\sqrt{x-1}}$

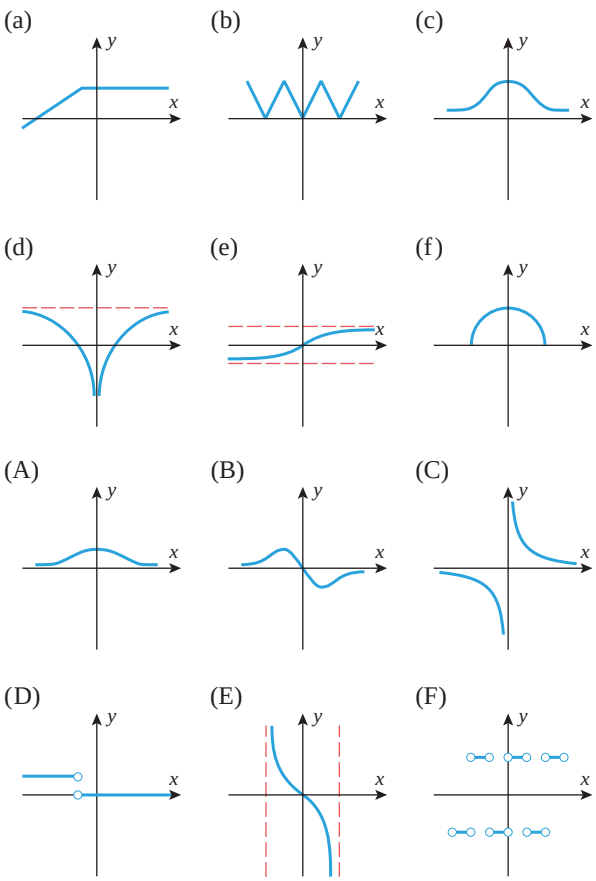
**21–22** Use Definition 2.2.1 (with appropriate change in notation) to obtain the derivative requested. ■

**21.** Find $f'(t)$ if $f(t) = 4t^2 + t$.

**22.** Find $dV/dr$ if $V = \frac{4}{3}\pi r^3$.

### FOCUS ON CONCEPTS

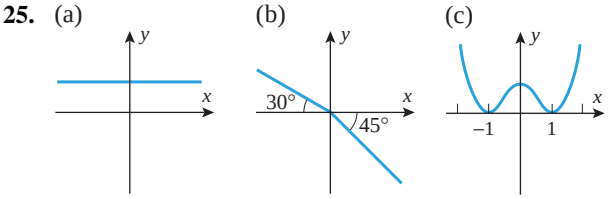
**23.** Match the graphs of the functions shown in (a)–(f) with the graphs of their derivatives in (A)–(F).



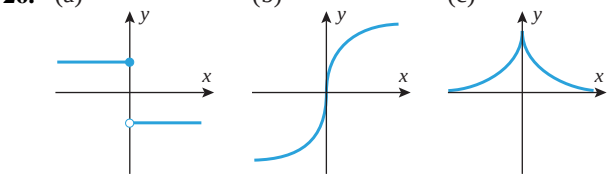
**24.** Let $f(x) = \sqrt{1 - x^2}$. Use a geometric argument to find $f'(\sqrt{2}/2)$.

**25–26** Sketch the graph of the derivative of the function whose graph is shown.

**25.**



**26.**



**27–30 True–False** Determine whether the statement is true or false. Explain your answer.

**27.** If a curve $y = f(x)$ has a horizontal tangent line at $x = a$, then $f'(a)$ is not defined.

**28.** If the tangent line to the graph of $y = f(x)$ at $x = -2$ has negative slope, then $f'(-2) < 0$.

**29.** If a function $f$ is continuous at $x = 0$, then $f$ is differentiable at $x = 0$.

**30.** If a function $f$ is differentiable at $x = 0$, then $f$ is continuous at $x = 0$.

**31–32** The given limit represents $f'(a)$ for some function $f$ and some number $a$. Find $f(x)$ and $a$ in each case.

**31.** (a) $\displaystyle\lim_{\Delta x \to 0} \frac{\sqrt{1 + \Delta x} - 1}{\Delta x}$ (b) $\displaystyle\lim_{x_1 \to 3} \frac{x_1^2 - 9}{x_1 - 3}$

**32.** (a) $\displaystyle\lim_{h \to 0} \frac{\cos(\pi + h) + 1}{h}$ (b) $\displaystyle\lim_{x \to 1} \frac{x^7 - 1}{x - 1}$

**33.** Find $dy/dx|_{x=1}$, given that $y = 1 - x^2$.

**34.** Find $dy/dx|_{x=-2}$, given that $y = (x + 2)/x$.

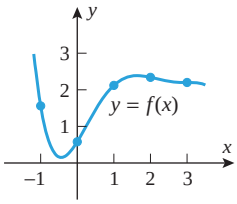
**35.** Find an equation for the line that is tangent to the curve $y = x^3 - 2x + 1$ at the point $(0, 1)$, and use a graphing utility to graph the curve and its tangent line on the same screen.

**36.** Use a graphing utility to graph the following on the same screen: the curve $y = x^2/4$, the tangent line to this curve at $x = 1$, and the secant line joining the points $(0, 0)$ and $(2, 1)$ on this curve.

**37.** Let $f(x) = 2^x$. Estimate $f'(1)$ by
(a) using a graphing utility to zoom in at an appropriate point until the graph looks like a straight line, and then estimating the slope
(b) using a calculating utility to estimate the limit in Formula (13) by making a table of values for a succession of values of $w$ approaching 1.

**38.** Let $f(x) = \sin x$. Estimate $f'(\pi/4)$ by
(a) using a graphing utility to zoom in at an appropriate point until the graph looks like a straight line, and then estimating the slope
(b) using a calculating utility to estimate the limit in Formula (13) by making a table of values for a succession of values of $w$ approaching $\pi/4$.

**39–40** The function $f$ whose graph is shown below has values as given in the accompanying table.



| $x$ | −1 | 0 | 1 | 2 | 3 |
|---|---|---|---|---|---|
| $f(x)$ | 1.56 | 0.58 | 2.12 | 2.34 | 2.2 |

**39.** (a) Use data from the table to calculate the difference quotients

$$\frac{f(3) - f(1)}{3 - 1}, \quad \frac{f(2) - f(1)}{2 - 1}, \quad \frac{f(2) - f(0)}{2 - 0}$$

(b) Using the graph of $y = f(x)$, indicate which difference quotient in part (a) best approximates $f'(1)$ and which difference quotient gives the worst approximation to $f'(1)$.

**40.** Use data from the table to approximate the derivative values.
(a) $f'(0.5)$ (b) $f'(2.5)$

**FOCUS ON CONCEPTS**

**41.** Suppose that the cost of drilling $x$ feet for an oil well is $C = f(x)$ dollars.
(a) What are the units of $f'(x)$?
(b) In practical terms, what does $f'(x)$ mean in this case?
(c) What can you say about the sign of $f'(x)$?
(d) Estimate the cost of drilling an additional foot, starting at a depth of 300 ft, given that $f'(300) = 1000$.

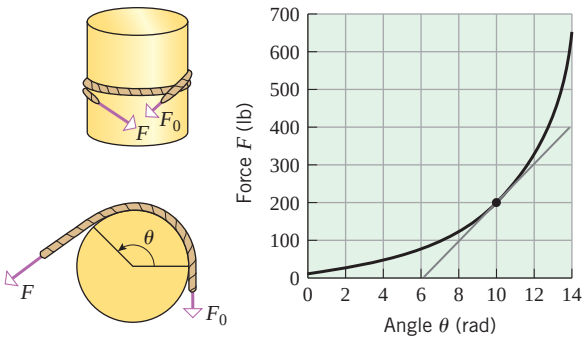
**42.** A paint manufacturing company estimates that it can sell $g = f(p)$ gallons of paint at a price of $p$ dollars per gallon.
(a) What are the units of $dg/dp$?
(b) In practical terms, what does $dg/dp$ mean in this case?
(c) What can you say about the sign of $dg/dp$?
(d) Given that $dg/dp|_{p=10} = -100$, what can you say about the effect of increasing the price from \$10 per gallon to \$11 per gallon?

**43.** It is a fact that when a flexible rope is wrapped around a rough cylinder, a small force of magnitude $F_0$ at one end can resist a large force of magnitude $F$ at the other end. The size of $F$ depends on the angle $\theta$ through which the rope is wrapped around the cylinder (see the

accompanying figure). The figure shows the graph of $F$ (in pounds) versus $\theta$ (in radians), where $F$ is the magnitude of the force that can be resisted by a force with magnitude $F_0 = 10$ lb for a certain rope and cylinder.

(a) Estimate the values of $F$ and $dF/d\theta$ when the angle $\theta = 10$ radians.

(b) It can be shown that the force $F$ satisfies the equation $dF/d\theta = \mu F$, where the constant $\mu$ is called the ***coefficient of friction***. Use the results in part (a) to estimate the value of $\mu$.

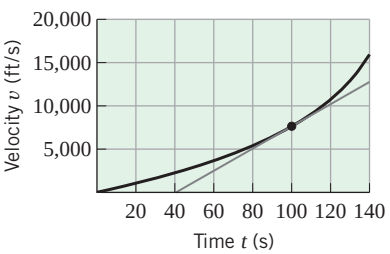


▲ **Figure Ex-43**

**44.** The accompanying figure shows the velocity versus time curve for a rocket in outer space where the only significant force on the rocket is from its engines. It can be shown that the mass $M(t)$ (in slugs) of the rocket at time $t$ seconds satisfies the equation

$$M(t) = \frac{T}{dv/dt}$$

where $T$ is the thrust (in lb) of the rocket's engines and $v$ is the velocity (in ft/s) of the rocket. The thrust of the first stage of a *Saturn V* rocket is $T = 7{,}680{,}982$ lb. Use this value of $T$ and the line segment in the figure to estimate the mass of the rocket at time $t = 100$.



◀ **Figure Ex-44**

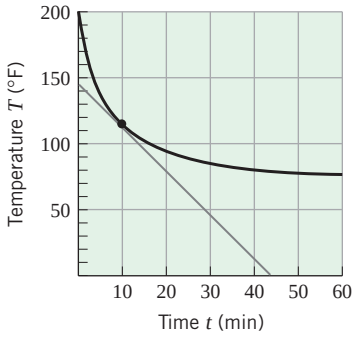
**45.** According to ***Newton's Law of Cooling***, the rate of change of an object's temperature is proportional to the difference between the temperature of the object and that of the surrounding medium. The accompanying figure shows the graph of the temperature $T$ (in degrees Fahrenheit) versus time $t$ (in minutes) for a cup of coffee, initially with a temperature of 200°F, that is allowed to cool in a room with a constant temperature of 75°F.

(a) Estimate $T$ and $dT/dt$ when $t = 10$ min.

(b) Newton's Law of Cooling can be expressed as

$$\frac{dT}{dt} = k(T - T_0)$$

where $k$ is the constant of proportionality and $T_0$ is the temperature (assumed constant) of the surrounding medium. Use the results in part (a) to estimate the value of $k$.



◀ **Figure Ex-45**

**46.** Show that $f(x)$ is continuous but not differentiable at the indicated point. Sketch the graph of $f$.

(a) $f(x) = \sqrt[3]{x}$, $x = 0$

(b) $f(x) = \sqrt[3]{(x-2)^2}$, $x = 2$

**47.** Show that

$$f(x) = \begin{cases} x^2 + 1, & x \le 1 \\ 2x, & x > 1 \end{cases}$$

is continuous and differentiable at $x = 1$. Sketch the graph of $f$.

**48.** Show that

$$f(x) = \begin{cases} x^2 + 2, & x \le 1 \\ x + 2, & x > 1 \end{cases}$$

is continuous but not differentiable at $x = 1$. Sketch the graph of $f$.

**49.** Show that

$$f(x) = \begin{cases} x \sin(1/x), & x \ne 0 \\ 0, & x = 0 \end{cases}$$

is continuous but not differentiable at $x = 0$. Sketch the graph of $f$ near $x = 0$. (See Figure 1.6.6 and the remark following Example 5 in Section 1.6.)

**50.** Show that

$$f(x) = \begin{cases} x^2 \sin(1/x), & x \ne 0 \\ 0, & x = 0 \end{cases}$$

is continuous and differentiable at $x = 0$. Sketch the graph of $f$ near $x = 0$.

## FOCUS ON CONCEPTS

**51.** Suppose that a function $f$ is differentiable at $x_0$ and that $f'(x_0) > 0$. Prove that there exists an open interval containing $x_0$ such that if $x_1$ and $x_2$ are any two points in this interval with $x_1 < x_0 < x_2$, then $f(x_1) < f(x_0) < f(x_2)$.

**52.** Suppose that a function $f$ is differentiable at $x_0$ and define $g(x) = f(mx + b)$, where $m$ and $b$ are constants. Prove that if $x_1$ is a point at which $mx_1 + b = x_0$, then $g(x)$ is differentiable at $x_1$ and $g'(x_1) = mf'(x_0)$.

**53.** Suppose that a function $f$ is differentiable at $x = 0$ with $f(0) = f'(0) = 0$, and let $y = mx$, $m \neq 0$, denote any line of nonzero slope through the origin.

(a) Prove that there exists an open interval containing 0 such that for all nonzero $x$ in this interval $|f(x)| < \left|\frac{1}{2}mx\right|$. [*Hint:* Let $\epsilon = \frac{1}{2}|m|$ and apply Definition 1.4.1 to (5) with $x_0 = 0$.]

(b) Conclude from part (a) and the triangle inequality that there exists an open interval containing 0 such that $|f(x)| < |f(x) - mx|$ for all $x$ in this interval.

(c) Explain why the result obtained in part (b) may be interpreted to mean that the tangent line to the graph of $f$ at the origin is the best *linear* approximation to $f$ at that point.

**54.** Suppose that $f$ is differentiable at $x_0$. Modify the argument of Exercise 53 to prove that the tangent line to the graph of $f$ at the point $P(x_0, f(x_0))$ provides the best linear approximation to $f$ at $P$. [*Hint:* Suppose that $y = f(x_0) + m(x - x_0)$ is any line through $P(x_0, f(x_0))$ with slope $m \neq f'(x_0)$. Apply Definition 1.4.1 to (5) with $x = x_0 + h$ and $\epsilon = \frac{1}{2}|f'(x_0) - m|$.]

**55. Writing** Write a paragraph that explains what it means for a function to be differentiable. Include examples of functions that are not differentiable as well as examples of functions that are differentiable.

**56. Writing** Explain the relationship between continuity and differentiability.

## ✔ QUICK CHECK ANSWERS 2.2

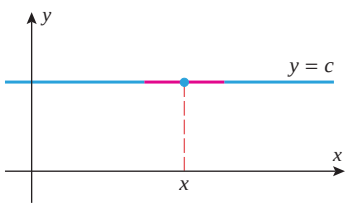
**1.** $\dfrac{f(x+h) - f(x)}{h}$ **2.** (a) $2x$ (b) $\dfrac{1}{2\sqrt{x}}$ **3.** 1; $-\frac{2}{3}$

**4.** Theorem 2.2.3: If $f$ is differentiable at $x_0$, then $f$ is continuous at $x_0$.

# 2.3 INTRODUCTION TO TECHNIQUES OF DIFFERENTIATION

*In the last section we defined the derivative of a function $f$ as a limit, and we used that limit to calculate a few simple derivatives. In this section we will develop some important theorems that will enable us to calculate derivatives more efficiently.*

## DERIVATIVE OF A CONSTANT



The tangent line to the graph of $f(x) = c$ has slope 0 for all $x$.

▲ **Figure 2.3.1**

The simplest kind of function is a constant function $f(x) = c$. Since the graph of $f$ is a horizontal line of slope 0, the tangent line to the graph of $f$ has slope 0 for every $x$; and hence we can see geometrically that $f'(x) = 0$ (Figure 2.3.1). We can also see this algebraically since

$$f'(x) = \lim_{h \to 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \to 0} \frac{c - c}{h} = \lim_{h \to 0} 0 = 0$$

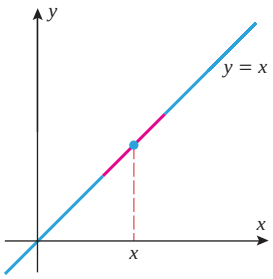
Thus, we have established the following result.

**2.3.1 THEOREM** *The derivative of a constant function is 0; that is, if $c$ is any real number, then*

$$\frac{d}{dx}[c] = 0 \tag{1}$$

### ▶ Example 1

$$\frac{d}{dx}[1] = 0, \quad \frac{d}{dx}[-3] = 0, \quad \frac{d}{dx}[\pi] = 0, \quad \frac{d}{dx}\left[-\sqrt{2}\right] = 0 \quad \blacktriangleleft$$



The tangent line to the graph of $f(x) = x$ has slope 1 for all $x$.

▲ Figure 2.3.2

## DERIVATIVES OF POWER FUNCTIONS

The simplest power function is $f(x) = x$. Since the graph of $f$ is a line of slope 1, it follows from Example 3 of Section 2.2 that $f'(x) = 1$ for all $x$ (Figure 2.3.2). In other words,

$$\frac{d}{dx}[x] = 1 \tag{2}$$

Example 1 of Section 2.2 shows that the power function $f(x) = x^2$ has derivative $f'(x) = 2x$. From Example 2 in that section one can infer that the power function $f(x) = x^3$ has derivative $f'(x) = 3x^2$. That is,

$$\frac{d}{dx}[x^2] = 2x \quad \text{and} \quad \frac{d}{dx}[x^3] = 3x^2 \tag{3–4}$$

These results are special cases of the following more general result.

**2.3.2 THEOREM (*The Power Rule*)** *If $n$ is a positive integer, then*

$$\frac{d}{dx}[x^n] = nx^{n-1} \tag{5}$$

Verify that Formulas (2), (3), and (4) are the special cases of (5) in which $n = 1$, 2, and 3.

The binomial formula can be found on the front endpaper of the text. Replacing $y$ by $h$ in this formula yields the identity used in the proof of Theorem 2.3.2.

**PROOF** Let $f(x) = x^n$. Thus, from the definition of a derivative and the binomial formula for expanding the expression $(x + h)^n$, we obtain

$$\begin{aligned}
\frac{d}{dx}[x^n] = f'(x) &= \lim_{h\to 0}\frac{f(x+h)-f(x)}{h} = \lim_{h\to 0}\frac{(x+h)^n - x^n}{h} \\
&= \lim_{h\to 0}\frac{\left[x^n + nx^{n-1}h + \dfrac{n(n-1)}{2!}x^{n-2}h^2 + \cdots + nxh^{n-1} + h^n\right] - x^n}{h} \\
&= \lim_{h\to 0}\frac{nx^{n-1}h + \dfrac{n(n-1)}{2!}x^{n-2}h^2 + \cdots + nxh^{n-1} + h^n}{h} \\
&= \lim_{h\to 0}\left[nx^{n-1} + \frac{n(n-1)}{2!}x^{n-2}h + \cdots + nxh^{n-2} + h^{n-1}\right] \\
&= nx^{n-1} + 0 + \cdots + 0 + 0 \\
&= nx^{n-1} \quad \blacksquare
\end{aligned}$$

### ▶ Example 2

$$\frac{d}{dx}[x^4] = 4x^3, \quad \frac{d}{dx}[x^5] = 5x^4, \quad \frac{d}{dt}[t^{12}] = 12t^{11} \quad \blacktriangleleft$$

Although our proof of the power rule in Formula (5) applies only to *positive* integer powers of $x$, it is not difficult to show that the same formula holds for all integer powers of $x$ (Exercise 82). Also, we saw in Example 4 of Section 2.2 that

$$\frac{d}{dx}[\sqrt{x}] = \frac{1}{2\sqrt{x}} \tag{6}$$

which can be expressed as

$$\frac{d}{dx}[x^{1/2}] = \frac{1}{2}x^{-1/2} = \frac{1}{2}x^{(1/2)-1}$$

Thus, Formula (5) is valid for $n = \frac{1}{2}$, as well. In fact, it can be shown that this formula holds for any real exponent. We state this more general result for our use now, although we won't be prepared to prove it until Chapter 3.

**2.3.3 THEOREM (*Extended Power Rule*)** *If $r$ is any real number, then*

$$\frac{d}{dx}[x^r] = rx^{r-1} \tag{7}$$

In words, *to differentiate a power function, decrease the constant exponent by one and multiply the resulting power function by the original exponent.*

### ▶ Example 3

$$\frac{d}{dx}[x^\pi] = \pi x^{\pi-1}$$

$$\frac{d}{dx}\left[\frac{1}{x}\right] = \frac{d}{dx}[x^{-1}] = (-1)x^{-1-1} = -x^{-2} = -\frac{1}{x^2}$$

$$\frac{d}{dw}\left[\frac{1}{w^{100}}\right] = \frac{d}{dw}[w^{-100}] = -100w^{-101} = -\frac{100}{w^{101}}$$

$$\frac{d}{dx}[x^{4/5}] = \frac{4}{5}x^{(4/5)-1} = \frac{4}{5}x^{-1/5}$$

$$\frac{d}{dx}[\sqrt[3]{x}] = \frac{d}{dx}[x^{1/3}] = \frac{1}{3}x^{-2/3} = \frac{1}{3\sqrt[3]{x^2}}$$ ◀

## DERIVATIVE OF A CONSTANT TIMES A FUNCTION

Formula (8) can also be expressed in function notation as

$$(cf)' = cf'$$

**2.3.4 THEOREM (*Constant Multiple Rule*)** *If $f$ is differentiable at $x$ and $c$ is any real number, then $cf$ is also differentiable at $x$ and*

$$\frac{d}{dx}[cf(x)] = c\frac{d}{dx}[f(x)] \tag{8}$$

**PROOF**

$$\frac{d}{dx}[cf(x)] = \lim_{h\to 0}\frac{cf(x+h) - cf(x)}{h}$$

$$= \lim_{h\to 0} c\left[\frac{f(x+h) - f(x)}{h}\right]$$

$$= c\lim_{h\to 0}\frac{f(x+h) - f(x)}{h}$$

A constant factor can be moved through a limit sign.

$$= c\frac{d}{dx}[f(x)]$$ ■

In words, *a constant factor can be moved through a derivative sign.*

▶ **Example 4**

$$\frac{d}{dx}[4x^8] = 4\frac{d}{dx}[x^8] = 4[8x^7] = 32x^7$$

$$\frac{d}{dx}[-x^{12}] = (-1)\frac{d}{dx}[x^{12}] = -12x^{11}$$

$$\frac{d}{dx}\left[\frac{\pi}{x}\right] = \pi\frac{d}{dx}[x^{-1}] = \pi(-x^{-2}) = -\frac{\pi}{x^2}$$ ◀

## DERIVATIVES OF SUMS AND DIFFERENCES

**2.3.5 THEOREM (*Sum and Difference Rules*)** *If $f$ and $g$ are differentiable at $x$, then so are $f + g$ and $f - g$ and*

$$\frac{d}{dx}[f(x) + g(x)] = \frac{d}{dx}[f(x)] + \frac{d}{dx}[g(x)] \tag{9}$$

$$\frac{d}{dx}[f(x) - g(x)] = \frac{d}{dx}[f(x)] - \frac{d}{dx}[g(x)] \tag{10}$$

Formulas (9) and (10) can also be expressed as

$$(f + g)' = f' + g'$$
$$(f - g)' = f' - g'$$

**PROOF** Formula (9) can be proved as follows:

$$\frac{d}{dx}[f(x) + g(x)] = \lim_{h\to 0}\frac{[f(x+h) + g(x+h)] - [f(x) + g(x)]}{h}$$

$$= \lim_{h\to 0}\frac{[f(x+h) - f(x)] + [g(x+h) - g(x)]}{h}$$

$$= \lim_{h\to 0}\frac{f(x+h) - f(x)}{h} + \lim_{h\to 0}\frac{g(x+h) - g(x)}{h}$$

The limit of a sum is the sum of the limits.

$$= \frac{d}{dx}[f(x)] + \frac{d}{dx}[g(x)]$$

Formula (10) can be proved in a similar manner or, alternatively, by writing $f(x) - g(x)$ as $f(x) + (-1)g(x)$ and then applying Formulas (8) and (9). ■

In words, *the derivative of a sum equals the sum of the derivatives*, and *the derivative of a difference equals the difference of the derivatives.*

▶ **Example 5**

$$\frac{d}{dx}[2x^6 + x^{-9}] = \frac{d}{dx}[2x^6] + \frac{d}{dx}[x^{-9}] = 12x^5 + (-9)x^{-10} = 12x^5 - 9x^{-10}$$

$$\frac{d}{dx}\left[\frac{\sqrt{x} - 2x}{\sqrt{x}}\right] = \frac{d}{dx}[1 - 2\sqrt{x}\,]$$

$$= \frac{d}{dx}[1] - \frac{d}{dx}[2\sqrt{x}\,] = 0 - 2\left(\frac{1}{2\sqrt{x}}\right) = -\frac{1}{\sqrt{x}}$$

See Formula (6). ◀

Although Formulas (9) and (10) are stated for sums and differences of two functions, they can be extended to any finite number of functions. For example, by grouping and applying Formula (9) twice we obtain

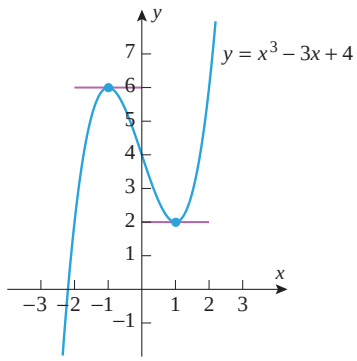
$$(f+g+h)' = [(f+g)+h]' = (f+g)' + h' = f' + g' + h'$$

As illustrated in the following example, the constant multiple rule together with the extended versions of the sum and difference rules can be used to differentiate any polynomial.

**▶ Example 6** Find $dy/dx$ if $y = 3x^8 - 2x^5 + 6x + 1$.

***Solution.***

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx}[3x^8 - 2x^5 + 6x + 1] \\ &= \frac{d}{dx}[3x^8] - \frac{d}{dx}[2x^5] + \frac{d}{dx}[6x] + \frac{d}{dx}[1] \\ &= 24x^7 - 10x^4 + 6 \quad \blacktriangleleft\end{aligned}$$



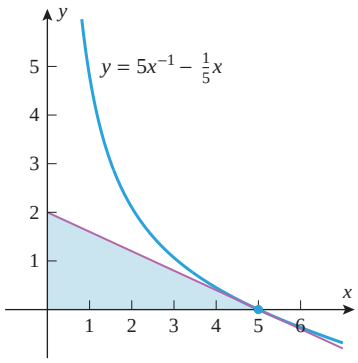
▲ **Figure 2.3.3**

**▶ Example 7** At what points, if any, does the graph of $y = x^3 - 3x + 4$ have a horizontal tangent line?

***Solution.*** Horizontal tangent lines have slope zero, so we must find those values of $x$ for which $y'(x) = 0$. Differentiating yields

$$y'(x) = \frac{d}{dx}[x^3 - 3x + 4] = 3x^2 - 3$$

Thus, horizontal tangent lines occur at those values of $x$ for which $3x^2 - 3 = 0$, that is, if $x = -1$ or $x = 1$. The corresponding points on the curve $y = x^3 - 3x + 4$ are $(-1, 6)$ and $(1, 2)$ (see Figure 2.3.3). ◀



▲ **Figure 2.3.4**

**▶ Example 8** Find the area of the triangle formed from the coordinate axes and the tangent line to the curve $y = 5x^{-1} - \frac{1}{5}x$ at the point $(5, 0)$.

***Solution.*** Since the derivative of $y$ with respect to $x$ is

$$y'(x) = \frac{d}{dx}\left[5x^{-1} - \frac{1}{5}x\right] = \frac{d}{dx}[5x^{-1}] - \frac{d}{dx}\left[\frac{1}{5}x\right] = -5x^{-2} - \frac{1}{5}$$

the slope of the tangent line at the point $(5, 0)$ is $y'(5) = -\frac{2}{5}$. Thus, the equation of the tangent line at this point is

$$y - 0 = -\frac{2}{5}(x - 5) \quad \text{or equivalently} \quad y = -\frac{2}{5}x + 2$$

Since the $y$-intercept of this line is 2, the right triangle formed from the coordinate axes and the tangent line has legs of length 5 and 2, so its area is $\frac{1}{2}(5)(2) = 5$ (Figure 2.3.4). ◀

## HIGHER DERIVATIVES

The derivative $f'$ of a function $f$ is itself a function and hence may have a derivative of its own. If $f'$ is differentiable, then its derivative is denoted by $f''$ and is called the ***second derivative*** of $f$. As long as we have differentiability, we can continue the process

of differentiating to obtain third, fourth, fifth, and even higher derivatives of $f$. These successive derivatives are denoted by

$$f', \quad f'' = (f')', \quad f''' = (f'')', \quad f^{(4)} = (f''')', \quad f^{(5)} = (f^{(4)})', \ldots$$

If $y = f(x)$, then successive derivatives can also be denoted by

$$y', \quad y'', \quad y''', \quad y^{(4)}, \quad y^{(5)}, \ldots$$

Other common notations are

$$y' = \frac{dy}{dx} = \frac{d}{dx}[f(x)]$$

$$y'' = \frac{d^2y}{dx^2} = \frac{d}{dx}\left[\frac{d}{dx}[f(x)]\right] = \frac{d^2}{dx^2}[f(x)]$$

$$y''' = \frac{d^3y}{dx^3} = \frac{d}{dx}\left[\frac{d^2}{dx^2}[f(x)]\right] = \frac{d^3}{dx^3}[f(x)]$$

$$\vdots \qquad\qquad \vdots$$

These are called, in succession, the *first derivative*, the *second derivative*, the *third derivative*, and so forth. The number of times that $f$ is differentiated is called the ***order*** of the derivative. A general $n$th order derivative can be denoted by

$$\frac{d^n y}{dx^n} = f^{(n)}(x) = \frac{d^n}{dx^n}[f(x)] \tag{11}$$

and the value of a general $n$th order derivative at a specific point $x = x_0$ can be denoted by

$$\left.\frac{d^n y}{dx^n}\right|_{x=x_0} = f^{(n)}(x_0) = \left.\frac{d^n}{dx^n}[f(x)]\right|_{x=x_0} \tag{12}$$

▶ **Example 9** If $f(x) = 3x^4 - 2x^3 + x^2 - 4x + 2$, then

$$f'(x) = 12x^3 - 6x^2 + 2x - 4$$
$$f''(x) = 36x^2 - 12x + 2$$
$$f'''(x) = 72x - 12$$
$$f^{(4)}(x) = 72$$
$$f^{(5)}(x) = 0$$
$$\vdots$$
$$f^{(n)}(x) = 0 \quad (n \geq 5)$$ ◀

We will discuss the significance of second derivatives and those of higher order in later sections.

## ✔ QUICK CHECK EXERCISES 2.3 (See page 163 for answers.)

**1.** In each part, determine $f'(x)$.
(a) $f(x) = \sqrt{6}$ (b) $f(x) = \sqrt{6x}$
(c) $f(x) = 6\sqrt{x}$ (d) $f(x) = \sqrt{6x}$

**2.** In parts (a)–(d), determine $f'(x)$.
(a) $f(x) = x^3 + 5$ (b) $f(x) = x^2(x^3 + 5)$
(c) $f(x) = \dfrac{x^3 + 5}{2}$ (d) $f(x) = \dfrac{x^3 + 5}{x^2}$

**3.** The slope of the tangent line to the curve $y = x^2 + 4x + 7$ at $x = 1$ is _____.

**4.** If $f(x) = 3x^3 - 3x^2 + x + 1$, then $f''(x) =$ _____.

## EXERCISE SET 2.3

Graphing Utility

**1–8** Find $dy/dx$.

**1.** $y = 4x^7$

**2.** $y = -3x^{12}$

**3.** $y = 3x^8 + 2x + 1$

**4.** $y = \frac{1}{2}(x^4 + 7)$

**5.** $y = \pi^3$

**6.** $y = \sqrt{2}x + (1/\sqrt{2})$

**7.** $y = -\frac{1}{3}(x^7 + 2x - 9)$

**8.** $y = \dfrac{x^2 + 1}{5}$

**9–16** Find $f'(x)$.

**9.** $f(x) = x^{-3} + \dfrac{1}{x^7}$

**10.** $f(x) = \sqrt{x} + \dfrac{1}{x}$

**11.** $f(x) = -3x^{-8} + 2\sqrt{x}$

**12.** $f(x) = 7x^{-6} - 5\sqrt{x}$

**13.** $f(x) = x^e + \dfrac{1}{x^{\sqrt{10}}}$

**14.** $f(x) = \sqrt[3]{\dfrac{8}{x}}$

**15.** $f(x) = (3x^2 + 1)^2$

**16.** $f(x) = ax^3 + bx^2 + cx + d$ ($a, b, c, d$ constant)

**17–18** Find $y'(1)$.

**17.** $y = 5x^2 - 3x + 1$

**18.** $y = \dfrac{x^{3/2} + 2}{x}$

**19–20** Find $dx/dt$.

**19.** $x = t^2 - t$

**20.** $x = \dfrac{t^2 + 1}{3t}$

**21–24** Find $dy/dx|_{x=1}$.

**21.** $y = 1 + x + x^2 + x^3 + x^4 + x^5$

**22.** $y = \dfrac{1 + x + x^2 + x^3 + x^4 + x^5 + x^6}{x^3}$

**23.** $y = (1 - x)(1 + x)(1 + x^2)(1 + x^4)$

**24.** $y = x^{24} + 2x^{12} + 3x^8 + 4x^6$

**25–26** Approximate $f'(1)$ by considering the difference quotient

$$\frac{f(1 + h) - f(1)}{h}$$

for values of $h$ near 0, and then find the exact value of $f'(1)$ by differentiating.

**25.** $f(x) = x^3 - 3x + 1$

**26.** $f(x) = \dfrac{1}{x^2}$

**27–28** Use a graphing utility to estimate the value of $f'(1)$ by zooming in on the graph of $f$, and then compare your estimate to the exact value obtained by differentiating.

**27.** $f(x) = \dfrac{x^2 + 1}{x}$

**28.** $f(x) = \dfrac{x + 2x^{3/2}}{\sqrt{x}}$

**29–32** Find the indicated derivative.

**29.** $\dfrac{d}{dt}[16t^2]$

**30.** $\dfrac{dC}{dr}$, where $C = 2\pi r$

**31.** $V'(r)$, where $V = \pi r^3$

**32.** $\dfrac{d}{d\alpha}[2\alpha^{-1} + \alpha]$

**33–36 True–False** Determine whether the statement is true or false. Explain your answer.

**33.** If $f$ and $g$ are differentiable at $x = 2$, then

$$\frac{d}{dx}[f(x) - 8g(x)]\bigg|_{x=2} = f'(2) - 8g'(2)$$

**34.** If $f(x)$ is a cubic polynomial, then $f'(x)$ is a quadratic polynomial.

**35.** If $f'(2) = 5$, then

$$\frac{d}{dx}[4f(x) + x^3]\bigg|_{x=2} = \frac{d}{dx}[4f(x) + 8]\bigg|_{x=2} = 4f'(2) = 20$$

**36.** If $f(x) = x^2(x^4 - x)$, then

$$f''(x) = \frac{d}{dx}[x^2] \cdot \frac{d}{dx}[x^4 - x] = 2x(4x^3 - 1)$$

**37.** A spherical balloon is being inflated.

(a) Find a general formula for the instantaneous rate of change of the volume $V$ with respect to the radius $r$, given that $V = \frac{4}{3}\pi r^3$.

(b) Find the rate of change of $V$ with respect to $r$ at the instant when the radius is $r = 5$.

**38.** Find $\dfrac{d}{d\lambda}\left[\dfrac{\lambda\lambda_0 + \lambda^6}{2 - \lambda_0}\right]$ ($\lambda_0$ is constant).

**39.** Find an equation of the tangent line to the graph of $y = f(x)$ at $x = -3$ if $f(-3) = 2$ and $f'(-3) = 5$.

**40.** Find an equation of the tangent line to the graph of $y = f(x)$ at $x = 2$ if $f(2) = -2$ and $f'(2) = -1$.

**41–42** Find $d^2y/dx^2$.

**41.** (a) $y = 7x^3 - 5x^2 + x$ (b) $y = 12x^2 - 2x + 3$
(c) $y = \dfrac{x + 1}{x}$ (d) $y = (5x^2 - 3)(7x^3 + x)$

**42.** (a) $y = 4x^7 - 5x^3 + 2x$ (b) $y = 3x + 2$
(c) $y = \dfrac{3x - 2}{5x}$ (d) $y = (x^3 - 5)(2x + 3)$

**43–44** Find $y'''$.

**43.** (a) $y = x^{-5} + x^5$ (b) $y = 1/x$
(c) $y = ax^3 + bx + c$ ($a, b, c$ constant)

**44.** (a) $y = 5x^2 - 4x + 7$ (b) $y = 3x^{-2} + 4x^{-1} + x$
(c) $y = ax^4 + bx^2 + c$ ($a, b, c$ constant)

**45.** Find

(a) $f'''(2)$, where $f(x) = 3x^2 - 2$

(b) $\dfrac{d^2y}{dx^2}\bigg|_{x=1}$, where $y = 6x^5 - 4x^2$

(c) $\dfrac{d^4}{dx^4}[x^{-3}]\bigg|_{x=1}$.

**46.** Find
(a) $y'''(0)$, where $y = 4x^4 + 2x^3 + 3$
(b) $\left.\dfrac{d^4y}{dx^4}\right|_{x=1}$, where $y = \dfrac{6}{x^4}$.

**47.** Show that $y = x^3 + 3x + 1$ satisfies $y''' + xy'' - 2y' = 0$.

**48.** Show that if $x \neq 0$, then $y = 1/x$ satisfies the equation $x^3y'' + x^2y' - xy = 0$.

**49–50** Use a graphing utility to make rough estimates of the locations of all horizontal tangent lines, and then find their exact locations by differentiating. ■

**49.** $y = \frac{1}{3}x^3 - \frac{3}{2}x^2 + 2x$ **50.** $y = \dfrac{x^2 + 9}{x}$

**FOCUS ON CONCEPTS**

**51.** Find a function $y = ax^2 + bx + c$ whose graph has an $x$-intercept of 1, a $y$-intercept of $-2$, and a tangent line with a slope of $-1$ at the $y$-intercept.

**52.** Find $k$ if the curve $y = x^2 + k$ is tangent to the line $y = 2x$.

**53.** Find the $x$-coordinate of the point on the graph of $y = x^2$ where the tangent line is parallel to the secant line that cuts the curve at $x = -1$ and $x = 2$.

**54.** Find the $x$-coordinate of the point on the graph of $y = \sqrt{x}$ where the tangent line is parallel to the secant line that cuts the curve at $x = 1$ and $x = 4$.

**55.** Find the coordinates of all points on the graph of $y = 1 - x^2$ at which the tangent line passes through the point $(2, 0)$.

**56.** Show that any two tangent lines to the parabola $y = ax^2$, $a \neq 0$, intersect at a point that is on the vertical line halfway between the points of tangency.

**57.** Suppose that $L$ is the tangent line at $x = x_0$ to the graph of the cubic equation $y = ax^3 + bx$. Find the $x$-coordinate of the point where $L$ intersects the graph a second time.

**58.** Show that the segment of the tangent line to the graph of $y = 1/x$ that is cut off by the coordinate axes is bisected by the point of tangency.

**59.** Show that the triangle that is formed by any tangent line to the graph of $y = 1/x$, $x > 0$, and the coordinate axes has an area of 2 square units.

**60.** Find conditions on $a$, $b$, $c$, and $d$ so that the graph of the polynomial $f(x) = ax^3 + bx^2 + cx + d$ has
(a) exactly two horizontal tangents
(b) exactly one horizontal tangent
(c) no horizontal tangents.

**61.** Newton's Law of Universal Gravitation states that the magnitude $F$ of the force exerted by a point with mass $M$ on a point with mass $m$ is

$$F = \frac{GmM}{r^2}$$

where $G$ is a constant and $r$ is the distance between the bodies. Assuming that the points are moving, find a formula for the instantaneous rate of change of $F$ with respect to $r$.

**62.** In the temperature range between 0°C and 700°C the resistance $R$ [in ohms ($\Omega$)] of a certain platinum resistance thermometer is given by

$$R = 10 + 0.04124T - 1.779 \times 10^{-5}T^2$$

where $T$ is the temperature in degrees Celsius. Where in the interval from 0°C to 700°C is the resistance of the thermometer most sensitive and least sensitive to temperature changes? [*Hint:* Consider the size of $dR/dT$ in the interval $0 \leq T \leq 700$.]

**63–64** Use a graphing utility to make rough estimates of the intervals on which $f'(x) > 0$, and then find those intervals exactly by differentiating. ■

**63.** $f(x) = x - \dfrac{1}{x}$ **64.** $f(x) = x^3 - 3x$

**65–68** You are asked in these exercises to determine whether a piecewise-defined function $f$ is differentiable at a value $x = x_0$, where $f$ is defined by different formulas on different sides of $x_0$. You may use without proof the following result, which is a consequence of the Mean-Value Theorem (discussed in Section 4.8). ***Theorem***. *Let $f$ be continuous at $x_0$ and suppose that $\lim_{x \to x_0} f'(x)$ exists. Then $f$ is differentiable at $x_0$, and $f'(x_0) = \lim_{x \to x_0} f'(x)$.* ■

**65.** Show that

$$f(x) = \begin{cases} x^2 + x + 1, & x \leq 1 \\ 3x, & x > 1 \end{cases}$$

is continuous at $x = 1$. Determine whether $f$ is differentiable at $x = 1$. If so, find the value of the derivative there. Sketch the graph of $f$.

**66.** Let

$$f(x) = \begin{cases} x^2 - 16x, & x < 9 \\ \sqrt{x}, & x \geq 9 \end{cases}$$

Is $f$ continuous at $x = 9$? Determine whether $f$ is differentiable at $x = 9$. If so, find the value of the derivative there.

**67.** Let

$$f(x) = \begin{cases} x^2, & x \leq 1 \\ \sqrt{x}, & x > 1 \end{cases}$$

Determine whether $f$ is differentiable at $x = 1$. If so, find the value of the derivative there.

**68.** Let

$$f(x) = \begin{cases} x^3 + \frac{1}{16}, & x < \frac{1}{2} \\ \frac{3}{4}x^2, & x \geq \frac{1}{2} \end{cases}$$

Determine whether $f$ is differentiable at $x = \frac{1}{2}$. If so, find the value of the derivative there.

**69.** Find all points where $f$ fails to be differentiable. Justify your answer.
(a) $f(x) = |3x - 2|$ (b) $f(x) = |x^2 - 4|$

**70.** In each part, compute $f'$, $f''$, $f'''$, and then state the formula for $f^{(n)}$.
(a) $f(x) = 1/x$ (b) $f(x) = 1/x^2$
[*Hint:* The expression $(-1)^n$ has a value of 1 if $n$ is even and $-1$ if $n$ is odd. Use this expression in your answer.]

**71.** (a) Prove:

$$\frac{d^2}{dx^2}[cf(x)] = c\frac{d^2}{dx^2}[f(x)]$$

$$\frac{d^2}{dx^2}[f(x) + g(x)] = \frac{d^2}{dx^2}[f(x)] + \frac{d^2}{dx^2}[g(x)]$$

(b) Do the results in part (a) generalize to $n$th derivatives? Justify your answer.

**72.** Let $f(x) = x^8 - 2x + 3$; find

$$\lim_{w \to 2} \frac{f'(w) - f'(2)}{w - 2}$$

**73.** (a) Find $f^{(n)}(x)$ if $f(x) = x^n$, $n = 1, 2, 3, \ldots$.
(b) Find $f^{(n)}(x)$ if $f(x) = x^k$ and $n > k$, where $k$ is a positive integer.
(c) Find $f^{(n)}(x)$ if

$$f(x) = a_0 + a_1x + a_2x^2 + \cdots + a_nx^n$$

**74.** (a) Prove: If $f''(x)$ exists for each $x$ in $(a, b)$, then both $f$ and $f'$ are continuous on $(a, b)$.
(b) What can be said about the continuity of $f$ and its derivatives if $f^{(n)}(x)$ exists for each $x$ in $(a, b)$?

**75.** Let $f(x) = (mx + b)^n$, where $m$ and $b$ are constants and $n$ is an integer. Use the result of Exercise 52 in Section 2.2 to prove that $f'(x) = nm(mx + b)^{n-1}$.

**76–77** Verify the result of Exercise 75 for $f(x)$. ■

**76.** $f(x) = (2x + 3)^2$ **77.** $f(x) = (3x - 1)^3$

**78–81** Use the result of Exercise 75 to compute the derivative of the given function $f(x)$. ■

**78.** $f(x) = \dfrac{1}{x - 1}$

**79.** $f(x) = \dfrac{3}{(2x + 1)^2}$

**80.** $f(x) = \dfrac{x}{x + 1}$

**81.** $f(x) = \dfrac{2x^2 + 4x + 3}{x^2 + 2x + 1}$

**82.** The purpose of this exercise is to extend the power rule (Theorem 2.3.2) to any integer exponent. Let $f(x) = x^n$, where $n$ is any integer. If $n > 0$, then $f'(x) = nx^{n-1}$ by Theorem 2.3.2.
(a) Show that the conclusion of Theorem 2.3.2 holds in the case $n = 0$.
(b) Suppose that $n < 0$ and set $m = -n$ so that

$$f(x) = x^n = x^{-m} = \frac{1}{x^m}$$

Use Definition 2.2.1 and Theorem 2.3.2 to show that

$$\frac{d}{dx}\left[\frac{1}{x^m}\right] = -mx^{m-1} \cdot \frac{1}{x^{2m}}$$

and conclude that $f'(x) = nx^{n-1}$.

## ✔ QUICK CHECK ANSWERS 2.3

**1.** (a) 0 (b) $\sqrt{6}$ (c) $3/\sqrt{x}$ (d) $\sqrt{6}/(2\sqrt{x})$ **2.** (a) $3x^2$ (b) $5x^4 + 10x$ (c) $\frac{3}{2}x^2$ (d) $1 - 10x^{-3}$ **3.** 6 **4.** $18x - 6$

# 2.4 THE PRODUCT AND QUOTIENT RULES

*In this section we will develop techniques for differentiating products and quotients of functions whose derivatives are known.*

## ■ DERIVATIVE OF A PRODUCT

You might be tempted to conjecture that the derivative of a product of two functions is the product of their derivatives. However, a simple example will show this to be false. Consider the functions

$$f(x) = x \quad \text{and} \quad g(x) = x^2$$

The product of their derivatives is

$$f'(x)g'(x) = (1)(2x) = 2x$$

but their product is $h(x) = f(x)g(x) = x^3$, so the derivative of the product is

$$h'(x) = 3x^2$$

Thus, the derivative of the product is not equal to the product of the derivatives. The correct relationship, which is credited to Leibniz, is given by the following theorem.

**2.4.1 THEOREM (*The Product Rule*)** *If $f$ and $g$ are differentiable at $x$, then so is the product $f \cdot g$, and*

$$\frac{d}{dx}[f(x)g(x)] = f(x)\frac{d}{dx}[g(x)] + g(x)\frac{d}{dx}[f(x)] \tag{1}$$

Formula (1) can also be expressed as

$$(f \cdot g)' = f \cdot g' + g \cdot f'$$

**PROOF** Whereas the proofs of the derivative rules in the last section were straightforward applications of the derivative definition, a key step in this proof involves adding and subtracting the quantity $f(x+h)g(x)$ to the numerator in the derivative definition. This yields

$$\begin{aligned}
\frac{d}{dx}[f(x)g(x)] &= \lim_{h\to 0}\frac{f(x+h)\cdot g(x+h) - f(x)\cdot g(x)}{h} \\
&= \lim_{h\to 0}\frac{f(x+h)g(x+h) - f(x+h)g(x) + f(x+h)g(x) - f(x)g(x)}{h} \\
&= \lim_{h\to 0}\left[f(x+h)\cdot\frac{g(x+h)-g(x)}{h} + g(x)\cdot\frac{f(x+h)-f(x)}{h}\right] \\
&= \lim_{h\to 0} f(x+h)\cdot\lim_{h\to 0}\frac{g(x+h)-g(x)}{h} + \lim_{h\to 0} g(x)\cdot\lim_{h\to 0}\frac{f(x+h)-f(x)}{h} \\
&= \left[\lim_{h\to 0} f(x+h)\right]\frac{d}{dx}[g(x)] + \left[\lim_{h\to 0} g(x)\right]\frac{d}{dx}[f(x)] \\
&= f(x)\frac{d}{dx}[g(x)] + g(x)\frac{d}{dx}[f(x)]
\end{aligned}$$

[*Note:* In the last step $f(x+h) \to f(x)$ as $h \to 0$ because $f$ is continuous at $x$ by Theorem 2.2.3. Also, $g(x) \to g(x)$ as $h \to 0$ because $g(x)$ does not involve $h$ and hence is treated as constant for the limit.] ■

In words, *the derivative of a product of two functions is the first function times the derivative of the second plus the second function times the derivative of the first.*

▶ **Example 1** Find $dy/dx$ if $y = (4x^2 - 1)(7x^3 + x)$.

***Solution.*** There are two methods that can be used to find $dy/dx$. We can either use the product rule or we can multiply out the factors in $y$ and then differentiate. We will give both methods.

**Method 1.** (*Using the Product Rule*)

$$\frac{dy}{dx} = \frac{d}{dx}[(4x^2 - 1)(7x^3 + x)]$$

$$= (4x^2 - 1)\frac{d}{dx}[7x^3 + x] + (7x^3 + x)\frac{d}{dx}[4x^2 - 1]$$

$$= (4x^2 - 1)(21x^2 + 1) + (7x^3 + x)(8x) = 140x^4 - 9x^2 - 1$$

**Method 2.** (*Multiplying First*)

$$y = (4x^2 - 1)(7x^3 + x) = 28x^5 - 3x^3 - x$$

Thus,

$$\frac{dy}{dx} = \frac{d}{dx}[28x^5 - 3x^3 - x] = 140x^4 - 9x^2 - 1$$

which agrees with the result obtained using the product rule. ◀

▶ **Example 2** Find $ds/dt$ if $s = (1 + t)\sqrt{t}$.

***Solution.*** Applying the product rule yields

$$\frac{ds}{dt} = \frac{d}{dt}[(1 + t)\sqrt{t}]$$

$$= (1 + t)\frac{d}{dt}[\sqrt{t}] + \sqrt{t}\frac{d}{dt}[1 + t]$$

$$= \frac{1 + t}{2\sqrt{t}} + \sqrt{t} = \frac{1 + 3t}{2\sqrt{t}}$$ ◀

## DERIVATIVE OF A QUOTIENT

Just as the derivative of a product is not generally the product of the derivatives, so the derivative of a quotient is not generally the quotient of the derivatives. The correct relationship is given by the following theorem.

**2.4.2 THEOREM** (***The Quotient Rule***) *If $f$ and $g$ are both differentiable at $x$ and if $g(x) \neq 0$, then $f/g$ is differentiable at $x$ and*

$$\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] = \frac{g(x)\dfrac{d}{dx}[f(x)] - f(x)\dfrac{d}{dx}[g(x)]}{[g(x)]^2} \tag{2}$$

Formula (2) can also be expressed as

$$\left(\frac{f}{g}\right)' = \frac{g \cdot f' - f \cdot g'}{g^2}$$

**PROOF**

$$\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] = \lim_{h \to 0} \frac{\dfrac{f(x + h)}{g(x + h)} - \dfrac{f(x)}{g(x)}}{h} = \lim_{h \to 0} \frac{f(x + h) \cdot g(x) - f(x) \cdot g(x + h)}{h \cdot g(x) \cdot g(x + h)}$$

Adding and subtracting $f(x) \cdot g(x)$ in the numerator yields

$$\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] = \lim_{h\to 0} \frac{f(x+h)\cdot g(x) - f(x)\cdot g(x) - f(x)\cdot g(x+h) + f(x)\cdot g(x)}{h\cdot g(x)\cdot g(x+h)}$$

$$= \lim_{h\to 0} \frac{\left[g(x)\cdot \dfrac{f(x+h)-f(x)}{h}\right] - \left[f(x)\cdot \dfrac{g(x+h)-g(x)}{h}\right]}{g(x)\cdot g(x+h)}$$

$$= \frac{\lim\limits_{h\to 0} g(x) \cdot \lim\limits_{h\to 0} \dfrac{f(x+h)-f(x)}{h} - \lim\limits_{h\to 0} f(x) \cdot \lim\limits_{h\to 0} \dfrac{g(x+h)-g(x)}{h}}{\lim\limits_{h\to 0} g(x) \cdot \lim\limits_{h\to 0} g(x+h)}$$

$$= \frac{\left[\lim\limits_{h\to 0} g(x)\right]\cdot \dfrac{d}{dx}[f(x)] - \left[\lim\limits_{h\to 0} f(x)\right]\cdot \dfrac{d}{dx}[g(x)]}{\lim\limits_{h\to 0} g(x) \cdot \lim\limits_{h\to 0} g(x+h)}$$

$$= \frac{g(x)\dfrac{d}{dx}[f(x)] - f(x)\dfrac{d}{dx}[g(x)]}{[g(x)]^2}$$

[See the note at the end of the proof of Theorem 2.4.1 for an explanation of the last step.] ■

In words, *the derivative of a quotient of two functions is the denominator times the derivative of the numerator minus the numerator times the derivative of the denominator, all divided by the denominator squared.*

Sometimes it is better to simplify a function first than to apply the quotient rule immediately. For example, it is easier to differentiate

$$f(x) = \frac{x^{3/2} + x}{\sqrt{x}}$$

by rewriting it as

$$f(x) = x + \sqrt{x}$$

as opposed to using the quotient rule.

**▶ Example 3** Find $y'(x)$ for $y = \dfrac{x^3 + 2x^2 - 1}{x + 5}$.

***Solution.*** Applying the quotient rule yields

$$\frac{dy}{dx} = \frac{d}{dx}\left[\frac{x^3+2x^2-1}{x+5}\right] = \frac{(x+5)\dfrac{d}{dx}[x^3+2x^2-1] - (x^3+2x^2-1)\dfrac{d}{dx}[x+5]}{(x+5)^2}$$

$$= \frac{(x+5)(3x^2+4x) - (x^3+2x^2-1)(1)}{(x+5)^2}$$

$$= \frac{(3x^3+19x^2+20x) - (x^3+2x^2-1)}{(x+5)^2}$$

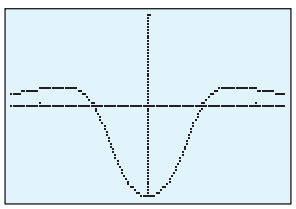
$$= \frac{2x^3+17x^2+20x+1}{(x+5)^2} \quad ◀$$

**▶ Example 4** Let $f(x) = \dfrac{x^2-1}{x^4+1}$.

(a) Graph $y = f(x)$, and use your graph to make rough estimates of the locations of all horizontal tangent lines.

(b) By differentiating, find the exact locations of the horizontal tangent lines.

***Solution (a).*** In Figure 2.4.1 we have shown the graph of the equation $y = f(x)$ in the window $[-2.5, 2.5] \times [-1, 1]$. This graph suggests that horizontal tangent lines occur at $x = 0$, $x \approx 1.5$, and $x \approx -1.5$.



[−2.5, 2.5] × [−1, 1]
xScl = 1, yScl = 1

$y = \dfrac{x^2-1}{x^4+1}$

▲ Figure 2.4.1

***Solution (b).*** To find the exact locations of the horizontal tangent lines, we must find the points where $dy/dx = 0$. We start by finding $dy/dx$:

$$\frac{dy}{dx} = \frac{d}{dx}\left[\frac{x^2-1}{x^4+1}\right] = \frac{(x^4+1)\dfrac{d}{dx}[x^2-1] - (x^2-1)\dfrac{d}{dx}[x^4+1]}{(x^4+1)^2}$$

$$= \frac{(x^4+1)(2x) - (x^2-1)(4x^3)}{(x^4+1)^2}$$

The differentiation is complete. The rest is simplification.

$$= \frac{-2x^5+4x^3+2x}{(x^4+1)^2} = -\frac{2x(x^4-2x^2-1)}{(x^4+1)^2}$$

Now we will set $dy/dx = 0$ and solve for $x$. We obtain

$$-\frac{2x(x^4-2x^2-1)}{(x^4+1)^2} = 0$$

The solutions of this equation are the values of $x$ for which the numerator is 0, that is,

$$2x(x^4-2x^2-1) = 0$$

The first factor yields the solution $x = 0$. Other solutions can be found by solving the equation

$$x^4 - 2x^2 - 1 = 0$$

This can be treated as a quadratic equation in $x^2$ and solved by the quadratic formula. This yields

$$x^2 = \frac{2 \pm \sqrt{8}}{2} = 1 \pm \sqrt{2}$$

The minus sign yields imaginary values of $x$, which we ignore since they are not relevant to the problem. The plus sign yields the solutions

$$x = \pm\sqrt{1+\sqrt{2}}$$

In summary, horizontal tangent lines occur at

$$x = 0, \quad x = \sqrt{1+\sqrt{2}} \approx 1.55, \quad \text{and} \quad x = -\sqrt{1+\sqrt{2}} \approx -1.55$$

which is consistent with the rough estimates that we obtained graphically in part (a). ◀

Derive the following rule for differentiating a reciprocal:

$$\left(\frac{1}{g}\right)' = -\frac{g'}{g^2}$$

Use it to find the derivative of

$$f(x) = \frac{1}{x^2+1}$$

## SUMMARY OF DIFFERENTIATION RULES

The following table summarizes the differentiation rules that we have encountered thus far.

**Table 2.4.1**

RULES FOR DIFFERENTIATION

| | | | |
|---|---|---|---|
| $\dfrac{d}{dx}[c] = 0$ | $(f+g)' = f' + g'$ | $(f \cdot g)' = f \cdot g' + g \cdot f'$ | $\left(\dfrac{1}{g}\right)' = -\dfrac{g'}{g^2}$ |
| $(cf)' = cf'$ | $(f-g)' = f' - g'$ | $\left(\dfrac{f}{g}\right)' = \dfrac{g \cdot f' - f \cdot g'}{g^2}$ | $\dfrac{d}{dx}[x^r] = rx^{r-1}$ |

## ✔ QUICK CHECK EXERCISES 2.4 (See page 169 for answers.)

**1.** (a) $\dfrac{d}{dx}[x^2 f(x)] =$ _____ (b) $\dfrac{d}{dx}\left[\dfrac{f(x)}{x^2+1}\right] =$ _____

(c) $\dfrac{d}{dx}\left[\dfrac{x^2+1}{f(x)}\right] =$ _____

**2.** Find $F'(1)$ given that $f(1) = -1$, $f'(1) = 2$, $g(1) = 3$, and $g'(1) = -1$.

(a) $F(x) = 2f(x) - 3g(x)$ (b) $F(x) = [f(x)]^2$

(c) $F(x) = f(x)g(x)$ (d) $F(x) = f(x)/g(x)$

## EXERCISE SET 2.4 Graphing Utility

**1–4** Compute the derivative of the given function $f(x)$ by (a) multiplying and then differentiating and (b) using the product rule. Verify that (a) and (b) yield the same result. ■

**1.** $f(x) = (x+1)(2x-1)$ **2.** $f(x) = (3x^2-1)(x^2+2)$

**3.** $f(x) = (x^2+1)(x^2-1)$

**4.** $f(x) = (x+1)(x^2-x+1)$

**5–20** Find $f'(x)$. ■

**5.** $f(x) = (3x^2+6)\left(2x-\frac{1}{4}\right)$

**6.** $f(x) = (2-x-3x^3)(7+x^5)$

**7.** $f(x) = (x^3+7x^2-8)(2x^{-3}+x^{-4})$

**8.** $f(x) = \left(\dfrac{1}{x}+\dfrac{1}{x^2}\right)(3x^3+27)$

**9.** $f(x) = (x-2)(x^2+2x+4)$

**10.** $f(x) = (x^2+x)(x^2-x)$

**11.** $f(x) = \dfrac{3x+4}{x^2+1}$ **12.** $f(x) = \dfrac{x-2}{x^4+x+1}$

**13.** $f(x) = \dfrac{x^2}{3x-4}$ **14.** $f(x) = \dfrac{2x^2+5}{3x-4}$

**15.** $f(x) = \dfrac{(2\sqrt{x}+1)(x-1)}{x+3}$

**16.** $f(x) = (2\sqrt{x}+1)\left(\dfrac{2-x}{x^2+3x}\right)$

**17.** $f(x) = (2x+1)\left(1+\dfrac{1}{x}\right)(x^{-3}+7)$

**18.** $f(x) = x^{-5}(x^2+2x)(4-3x)(2x^9+1)$

**19.** $f(x) = (x^7+2x-3)^3$ **20.** $f(x) = (x^2+1)^4$

**21–24** Find $dy/dx|_{x=1}$. ■

**21.** $y = \dfrac{2x-1}{x+3}$ **22.** $y = \dfrac{4x+1}{x^2-5}$

**23.** $y = \left(\dfrac{3x+2}{x}\right)(x^{-5}+1)$ **24.** $y = (2x^7-x^2)\left(\dfrac{x-1}{x+1}\right)$

**25–26** Use a graphing utility to estimate the value of $f'(1)$ by zooming in on the graph of $f$, and then compare your estimate to the exact value obtained by differentiating. ■

**25.** $f(x) = \dfrac{x}{x^2+1}$ **26.** $f(x) = \dfrac{x^2-1}{x^2+1}$

**27.** Find $g'(4)$ given that $f(4) = 3$ and $f'(4) = -5$.

(a) $g(x) = \sqrt{x}f(x)$ (b) $g(x) = \dfrac{f(x)}{x}$

**28.** Find $g'(3)$ given that $f(3) = -2$ and $f'(3) = 4$.

(a) $g(x) = 3x^2 - 5f(x)$ (b) $g(x) = \dfrac{2x+1}{f(x)}$

**29.** In parts (a)–(d), $F(x)$ is expressed in terms of $f(x)$ and $g(x)$. Find $F'(2)$ given that $f(2) = -1$, $f'(2) = 4$, $g(2) = 1$, and $g'(2) = -5$.

(a) $F(x) = 5f(x) + 2g(x)$ (b) $F(x) = f(x) - 3g(x)$

(c) $F(x) = f(x)g(x)$ (d) $F(x) = f(x)/g(x)$

**30.** Find $F'(\pi)$ given that $f(\pi) = 10$, $f'(\pi) = -1$, $g(\pi) = -3$, and $g'(\pi) = 2$.

(a) $F(x) = 6f(x) - 5g(x)$ (b) $F(x) = x(f(x) + g(x))$

(c) $F(x) = 2f(x)g(x)$ (d) $F(x) = \dfrac{f(x)}{4+g(x)}$

**31–36** Find all values of $x$ at which the tangent line to the given curve satisfies the stated property. ■

**31.** $y = \dfrac{x^2-1}{x+2}$; horizontal **32.** $y = \dfrac{x^2+1}{x-1}$; horizontal

**33.** $y = \dfrac{x^2+1}{x+1}$; parallel to the line $y = x$

**34.** $y = \dfrac{x+3}{x+2}$; perpendicular to the line $y = x$

**35.** $y = \dfrac{1}{x+4}$; passes through the origin

**36.** $y = \dfrac{2x+5}{x+2}$; $y$-intercept 2

### FOCUS ON CONCEPTS

**37.** (a) What should it mean to say that two curves intersect at right angles?

(b) Show that the curves $y = 1/x$ and $y = 1/(2-x)$ intersect at right angles.

**38.** Find all values of $a$ such that the curves $y = a/(x-1)$ and $y = x^2 - 2x + 1$ intersect at right angles.

**39.** Find a general formula for $F''(x)$ if $F(x) = xf(x)$ and $f$ and $f'$ are differentiable at $x$.

**40.** Suppose that the function $f$ is differentiable everywhere and $F(x) = xf(x)$.

(a) Express $F'''(x)$ in terms of $x$ and derivatives of $f$.

(b) For $n \geq 2$, conjecture a formula for $F^{(n)}(x)$.

**41.** A manufacturer of athletic footwear finds that the sales of their ZipStride brand running shoes is a function $f(p)$ of the selling price $p$ (in dollars) for a pair of shoes. Suppose that $f(120) = 9000$ pairs of shoes and $f'(120) = -60$ pairs of shoes per dollar. The revenue that the manufacturer will receive for selling $f(p)$ pairs of shoes at $p$ dollars per pair is $R(p) = p \cdot f(p)$. Find $R'(120)$. What impact would a small increase in price have on the manufacturer's revenue?

**42.** Solve the problem in Exercise 41 under the assumption that $f(120) = 9000$ and $f'(120) = -80$.

**43.** Use the quotient rule (Theorem 2.4.2) to derive the formula for the derivative of $f(x) = x^{-n}$, where $n$ is a positive integer.

### ✔ QUICK CHECK ANSWERS 2.4

**1.** (a) $x^2 f'(x) + 2xf(x)$ (b) $\dfrac{(x^2+1)f'(x) - 2xf(x)}{(x^2+1)^2}$ (c) $\dfrac{2xf(x) - (x^2+1)f'(x)}{[f(x)^2]}$ **2.** (a) 7 (b) $-4$ (c) 7 (d) $\frac{5}{9}$

## 2.5 DERIVATIVES OF TRIGONOMETRIC FUNCTIONS

*The main objective of this section is to obtain formulas for the derivatives of the six basic trigonometric functions. If needed, you will find a review of trigonometric functions in Appendix B.*

We will assume in this section that the variable $x$ in the trigonometric functions $\sin x$, $\cos x$, $\tan x$, $\cot x$, $\sec x$, and $\csc x$ is measured in radians. Also, we will need the limits in Theorem 1.6.5, but restated as follows using $h$ rather than $x$ as the variable:

$$\lim_{h\to 0} \frac{\sin h}{h} = 1 \quad \text{and} \quad \lim_{h\to 0} \frac{1-\cos h}{h} = 0 \tag{1–2}$$

Let us start with the problem of differentiating $f(x) = \sin x$. Using the definition of the derivative we obtain

$$\begin{aligned}
f'(x) &= \lim_{h\to 0} \frac{f(x+h) - f(x)}{h} \\
&= \lim_{h\to 0} \frac{\sin(x+h) - \sin x}{h} \\
&= \lim_{h\to 0} \frac{\sin x \cos h + \cos x \sin h - \sin x}{h} && \text{By the addition formula for sine} \\
&= \lim_{h\to 0} \left[\sin x \left(\frac{\cos h - 1}{h}\right) + \cos x \left(\frac{\sin h}{h}\right)\right] \\
&= \lim_{h\to 0} \left[\cos x \left(\frac{\sin h}{h}\right) - \sin x \left(\frac{1-\cos h}{h}\right)\right] && \text{Algebraic reorganization} \\
&= \lim_{h\to 0} \cos x \cdot \lim_{h\to 0} \frac{\sin h}{h} - \lim_{h\to 0} \sin x \cdot \lim_{h\to 0} \frac{1-\cos h}{h} \\
&= \left(\lim_{h\to 0} \cos x\right)(1) - \left(\lim_{h\to 0} \sin x\right)(0) && \text{Formulas (1) and (2)} \\
&= \lim_{h\to 0} \cos x = \cos x && \text{cos } x \text{ does not involve the variable } h \text{ and hence is treated as a constant in the limit computation.}
\end{aligned}$$

Thus, we have shown that

$$\frac{d}{dx}[\sin x] = \cos x \tag{3}$$

In the exercises we will ask you to use the same method to derive the following formula for the derivative of $\cos x$:

$$\frac{d}{dx}[\cos x] = -\sin x \tag{4}$$

Formulas (1) and (2) and the derivation of Formulas (3) and (4) are only valid if $h$ and $x$ are in radians. See Exercise 49 for how Formulas (3) and (4) change when $x$ is measured in degrees.

**▶ Example 1** Find $dy/dx$ if $y = x \sin x$.

***Solution.*** Using Formula (3) and the product rule we obtain

$$\begin{aligned}\frac{dy}{dx} &= \frac{d}{dx}[x \sin x] \\ &= x\frac{d}{dx}[\sin x] + \sin x \frac{d}{dx}[x] \\ &= x \cos x + \sin x \quad \blacktriangleleft\end{aligned}$$

**▶ Example 2** Find $dy/dx$ if $y = \dfrac{\sin x}{1 + \cos x}$.

***Solution.*** Using the quotient rule together with Formulas (3) and (4) we obtain

$$\begin{aligned}\frac{dy}{dx} &= \frac{(1 + \cos x) \cdot \dfrac{d}{dx}[\sin x] - \sin x \cdot \dfrac{d}{dx}[1 + \cos x]}{(1 + \cos x)^2} \\ &= \frac{(1 + \cos x)(\cos x) - (\sin x)(-\sin x)}{(1 + \cos x)^2} \\ &= \frac{\cos x + \cos^2 x + \sin^2 x}{(1 + \cos x)^2} = \frac{\cos x + 1}{(1 + \cos x)^2} = \frac{1}{1 + \cos x} \quad \blacktriangleleft\end{aligned}$$

Since Formulas (3) and (4) are valid only if $x$ is in radians, the same is true for Formulas (5)–(8).

The derivatives of the remaining trigonometric functions are

$$\frac{d}{dx}[\tan x] = \sec^2 x \qquad \frac{d}{dx}[\sec x] = \sec x \tan x \tag{5–6}$$

$$\frac{d}{dx}[\cot x] = -\csc^2 x \qquad \frac{d}{dx}[\csc x] = -\csc x \cot x \tag{7–8}$$

These can all be obtained using the definition of the derivative, but it is easier to use Formulas (3) and (4) and apply the quotient rule to the relationships

$$\tan x = \frac{\sin x}{\cos x}, \quad \cot x = \frac{\cos x}{\sin x}, \quad \sec x = \frac{1}{\cos x}, \quad \csc x = \frac{1}{\sin x}$$

For example,

$$\begin{aligned}\frac{d}{dx}[\tan x] &= \frac{d}{dx}\left[\frac{\sin x}{\cos x}\right] = \frac{\cos x \cdot \dfrac{d}{dx}[\sin x] - \sin x \cdot \dfrac{d}{dx}[\cos x]}{\cos^2 x} \\ &= \frac{\cos x \cdot \cos x - \sin x \cdot (-\sin x)}{\cos^2 x} = \frac{\cos^2 x + \sin^2 x}{\cos^2 x} = \frac{1}{\cos^2 x} = \sec^2 x\end{aligned}$$

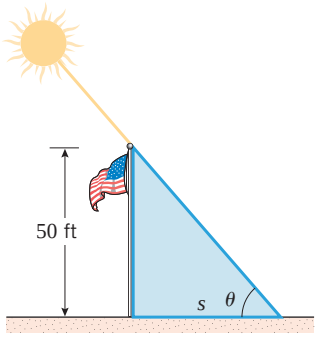
When finding the value of a derivative at a specific point $x = x_0$, it is important to substitute $x_0$ *after* the derivative is obtained. Thus, in Example 3 we made the substitution $x = \pi/4$ after $f''$ was calculated. What would have happened had we *incorrectly* substituted $x = \pi/4$ into $f'(x)$ before calculating $f''$?

**▶ Example 3** Find $f''(\pi/4)$ if $f(x) = \sec x$.

$$\begin{aligned}f'(x) &= \sec x \tan x \\ f''(x) &= \sec x \cdot \frac{d}{dx}[\tan x] + \tan x \cdot \frac{d}{dx}[\sec x] \\ &= \sec x \cdot \sec^2 x + \tan x \cdot \sec x \tan x \\ &= \sec^3 x + \sec x \tan^2 x\end{aligned}$$

Thus,

$$f''(\pi/4) = \sec^3(\pi/4) + \sec(\pi/4)\tan^2(\pi/4)$$
$$= (\sqrt{2})^3 + (\sqrt{2})(1)^2 = 3\sqrt{2} \quad \blacktriangleleft$$



▲ Figure 2.5.1

**▶ Example 4** On a sunny day, a 50 ft flagpole casts a shadow that changes with the angle of elevation of the Sun. Let $s$ be the length of the shadow and $\theta$ the angle of elevation of the Sun (Figure 2.5.1). Find the rate at which the length of the shadow is changing with respect to $\theta$ when $\theta = 45°$. Express your answer in units of feet/degree.

***Solution.*** The variables $s$ and $\theta$ are related by $\tan\theta = 50/s$ or, equivalently,

$$s = 50\cot\theta \tag{9}$$

If $\theta$ is measured in radians, then Formula (7) is applicable, which yields

$$\frac{ds}{d\theta} = -50\csc^2\theta$$

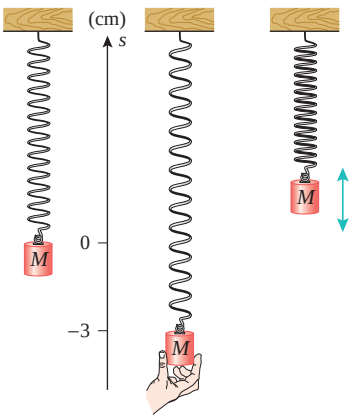
which is the rate of change of shadow length with respect to the elevation angle $\theta$ in units of feet/radian. When $\theta = 45°$ (or equivalently $\theta = \pi/4$ radians), we obtain

$$\left.\frac{ds}{d\theta}\right|_{\theta=\pi/4} = -50\csc^2(\pi/4) = -100 \text{ feet/radian}$$

Converting radians (rad) to degrees (deg) yields

$$-100\,\frac{\text{ft}}{\text{rad}}\cdot\frac{\pi}{180}\,\frac{\text{rad}}{\text{deg}} = -\frac{5}{9}\pi\,\frac{\text{ft}}{\text{deg}} \approx -1.75 \text{ ft/deg}$$

Thus, when $\theta = 45°$, the shadow length is decreasing (because of the minus sign) at an approximate rate of 1.75 ft/deg increase in the angle of elevation. ◀



▲ Figure 2.5.2

**▶ Example 5** As illustrated in Figure 2.5.2, suppose that a spring with an attached mass is stretched 3 cm beyond its rest position and released at time $t = 0$. Assuming that the position function of the top of the attached mass is

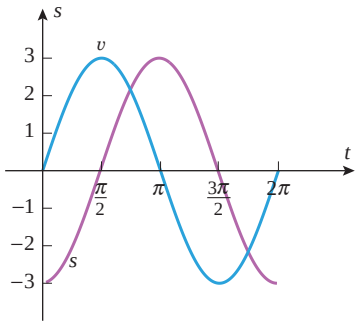
$$s = -3\cos t \tag{10}$$

where $s$ is in centimeters and $t$ is in seconds, find the velocity function and discuss the motion of the attached mass.

***Solution.*** The velocity function is

$$v = \frac{ds}{dt} = \frac{d}{dt}[-3\cos t] = 3\sin t$$

Figure 2.5.3 shows the graphs of the position and velocity functions. The position function tells us that the top of the mass oscillates between a low point of $s = -3$ and a high point of $s = 3$ with one complete oscillation occuring every $2\pi$ seconds [the period of (10)]. The top of the mass is moving up (the positive $s$-direction) when $v$ is positive, is moving down when $v$ is negative, and is at a high or low point when $v = 0$. Thus, for example, the top of the mass moves up from time $t = 0$ to time $t = \pi$, at which time it reaches the high point $s = 3$ and then moves down until time $t = 2\pi$, at which time it reaches the low point of $s = -3$. The motion then repeats periodically. ◀



▲ Figure 2.5.3

In Example 5, the top of the mass has its maximum speed when it passes through its rest position. Why? What is that maximum speed?

## ✔ QUICK CHECK EXERCISES 2.5 (See page 174 for answers.)

**1.** Find $dy/dx$.
(a) $y = \sin x$ (b) $y = \cos x$
(c) $y = \tan x$ (d) $y = \sec x$

**2.** Find $f'(x)$ and $f'(\pi/3)$ if $f(x) = \sin x \cos x$.

**3.** Use a derivative to evaluate each limit.
(a) $\lim_{h\to 0} \dfrac{\sin\left(\frac{\pi}{2}+h\right)-1}{h}$ (b) $\lim_{h\to 0} \dfrac{\csc(x+h)-\csc x}{h}$

## EXERCISE SET 2.5 Graphing Utility

**1–18** Find $f'(x)$. ■

**1.** $f(x) = 4\cos x + 2\sin x$

**2.** $f(x) = \dfrac{5}{x^2} + \sin x$

**3.** $f(x) = -4x^2 \cos x$

**4.** $f(x) = 2\sin^2 x$

**5.** $f(x) = \dfrac{5-\cos x}{5+\sin x}$

**6.** $f(x) = \dfrac{\sin x}{x^2+\sin x}$

**7.** $f(x) = \sec x - \sqrt{2}\tan x$

**8.** $f(x) = (x^2+1)\sec x$

**9.** $f(x) = 4\csc x - \cot x$

**10.** $f(x) = \cos x - x\csc x$

**11.** $f(x) = \sec x \tan x$

**12.** $f(x) = \csc x \cot x$

**13.** $f(x) = \dfrac{\cot x}{1+\csc x}$

**14.** $f(x) = \dfrac{\sec x}{1+\tan x}$

**15.** $f(x) = \sin^2 x + \cos^2 x$

**16.** $f(x) = \sec^2 x - \tan^2 x$

**17.** $f(x) = \dfrac{\sin x \sec x}{1+x\tan x}$

**18.** $f(x) = \dfrac{(x^2+1)\cot x}{3-\cos x \csc x}$

**19–24** Find $d^2y/dx^2$. ■

**19.** $y = x\cos x$

**20.** $y = \csc x$

**21.** $y = x\sin x - 3\cos x$

**22.** $y = x^2\cos x + 4\sin x$

**23.** $y = \sin x \cos x$

**24.** $y = \tan x$

**25.** Find the equation of the line tangent to the graph of $\tan x$ at
(a) $x = 0$ (b) $x = \pi/4$ (c) $x = -\pi/4$.

**26.** Find the equation of the line tangent to the graph of $\sin x$ at
(a) $x = 0$ (b) $x = \pi$ (c) $x = \pi/4$.

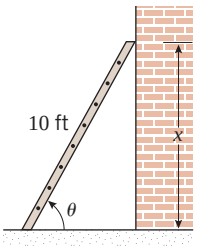
**27.** (a) Show that $y = x\sin x$ is a solution to $y'' + y = 2\cos x$.
(b) Show that $y = x\sin x$ is a solution of the equation $y^{(4)} + y'' = -2\cos x$.

**28.** (a) Show that $y = \cos x$ and $y = \sin x$ are solutions of the equation $y'' + y = 0$.
(b) Show that $y = A\sin x + B\cos x$ is a solution of the equation $y'' + y = 0$ for all constants $A$ and $B$.

**29.** Find all values in the interval $[-2\pi, 2\pi]$ at which the graph of $f$ has a horizontal tangent line.
(a) $f(x) = \sin x$ (b) $f(x) = x + \cos x$
(c) $f(x) = \tan x$ (d) $f(x) = \sec x$

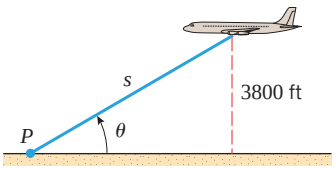
**30.** (a) Use a graphing utility to make rough estimates of the values in the interval $[0, 2\pi]$ at which the graph of $y = \sin x \cos x$ has a horizontal tangent line.
(b) Find the exact locations of the points where the graph has a horizontal tangent line.

**31.** A 10 ft ladder leans against a wall at an angle $\theta$ with the horizontal, as shown in the accompanying figure. The top of the ladder is $x$ feet above the ground. If the bottom of the ladder is pushed toward the wall, find the rate at which $x$ changes with respect to $\theta$ when $\theta = 60°$. Express the answer in units of feet/degree.



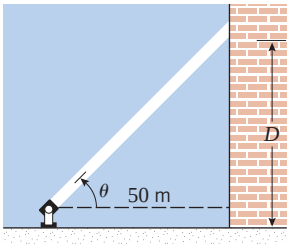
◀ **Figure Ex-31**

**32.** An airplane is flying on a horizontal path at a height of 3800 ft, as shown in the accompanying figure. At what rate is the distance $s$ between the airplane and the fixed point $P$ changing with respect to $\theta$ when $\theta = 30°$? Express the answer in units of feet/degree.



◀ **Figure Ex-32**

**33.** A searchlight is trained on the side of a tall building. As the light rotates, the spot it illuminates moves up and down the side of the building. That is, the distance $D$ between ground level and the illuminated spot on the side of the building is a function of the angle $\theta$ formed by the light beam and the horizontal (see the accompanying figure). If the searchlight is located 50 m from the building, find the rate at which $D$ is changing with respect to $\theta$ when $\theta = 45°$. Express your answer in units of meters/degree.



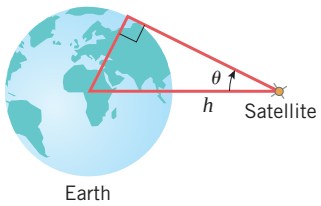
◀ **Figure Ex-33**

**34.** An Earth-observing satellite can see only a portion of the Earth's surface. The satellite has horizon sensors that can detect the angle $\theta$ shown in the accompanying figure. Let $r$ be the radius of the Earth (assumed spherical) and $h$ the distance of the satellite from the Earth's surface.

(a) Show that $h = r(\csc\theta - 1)$.

(b) Using $r = 6378$ km, find the rate at which $h$ is changing with respect to $\theta$ when $\theta = 30°$. Express the answer in units of kilometers/degree.

***Source:*** Adapted from *Space Mathematics*, NASA, 1985.



◀ **Figure Ex-34**

**35–38 True–False** Determine whether the statement is true or false. Explain your answer. ■

**35.** If $g(x) = f(x)\sin x$, then $g'(x) = f'(x)\cos x$.

**36.** If $g(x) = f(x)\sin x$, then $g'(0) = f(0)$.

**37.** If $f(x)\cos x = \sin x$, then $f'(x) = \sec^2 x$.

**38.** Suppose that $g(x) = f(x)\sec x$, where $f(0) = 8$ and $f'(0) = -2$. Then

$$g'(0) = \lim_{h\to 0}\frac{f(h)\sec h - f(0)}{h} = \lim_{h\to 0}\frac{8(\sec h - 1)}{h}$$

$$= 8\cdot\frac{d}{dx}[\sec x]\Big|_{x=0} = 8\sec 0\tan 0 = 0$$

**39–40** Make a conjecture about the derivative by calculating the first few derivatives and observing the resulting pattern. ■

**39.** $\dfrac{d^{87}}{dx^{87}}[\sin x]$ **40.** $\dfrac{d^{100}}{dx^{100}}[\cos x]$

**41.** Let $f(x) = \cos x$. Find all positive integers $n$ for which $f^{(n)}(x) = \sin x$.

**42.** Let $f(x) = \sin x$. Find all positive integers $n$ for which $f^{(n)}(x) = \sin x$.

**FOCUS ON CONCEPTS**

**43.** In each part, determine where $f$ is differentiable.

(a) $f(x) = \sin x$ (b) $f(x) = \cos x$

(c) $f(x) = \tan x$ (d) $f(x) = \cot x$

(e) $f(x) = \sec x$ (f) $f(x) = \csc x$

(g) $f(x) = \dfrac{1}{1+\cos x}$ (h) $f(x) = \dfrac{1}{\sin x\cos x}$

(i) $f(x) = \dfrac{\cos x}{2-\sin x}$

**44.** (a) Derive Formula (4) using the definition of a derivative.

(b) Use Formulas (3) and (4) to obtain (7).

(c) Use Formula (4) to obtain (6).

(d) Use Formula (3) to obtain (8).

**45.** Use Formula (1), the alternative form for the definition of derivative given in Formula (13) of Section 2.2, that is,

$$f'(x) = \lim_{w\to x}\frac{f(w) - f(x)}{w - x}$$

and the difference identity

$$\sin\alpha - \sin\beta = 2\sin\left(\frac{\alpha-\beta}{2}\right)\cos\left(\frac{\alpha+\beta}{2}\right)$$

to show that $\dfrac{d}{dx}[\sin x] = \cos x$.

**46.** Follow the directions of Exercise 45 using the difference identity

$$\cos\alpha - \cos\beta = -2\sin\left(\frac{\alpha-\beta}{2}\right)\sin\left(\frac{\alpha+\beta}{2}\right)$$

to show that $\dfrac{d}{dx}[\cos x] = -\sin x$.

**47.** (a) Show that $\lim_{h\to 0}\dfrac{\tan h}{h} = 1$.

(b) Use the result in part (a) to help derive the formula for the derivative of $\tan x$ directly from the definition of a derivative.

**48.** Without using any trigonometric identities, find

$$\lim_{x\to 0}\frac{\tan(x+y) - \tan y}{x}$$

[*Hint:* Relate the given limit to the definition of the derivative of an appropriate function of $y$.]

**49.** The derivative formulas for $\sin x$, $\cos x$, $\tan x$, $\cot x$, $\sec x$, and $\csc x$ were obtained under the assumption that $x$ is measured in radians. If $x$ is measured in degrees, then

$$\lim_{x\to 0}\frac{\sin x}{x} = \frac{\pi}{180}$$

(See Exercise 48 of Section 1.6). Use this result to prove that if $x$ is measured in degrees, then

(a) $\dfrac{d}{dx}[\sin x] = \dfrac{\pi}{180}\cos x$

(b) $\dfrac{d}{dx}[\cos x] = -\dfrac{\pi}{180}\sin x$.

**50. Writing** Suppose that $f$ is a function that is differentiable everywhere. Explain the relationship, if any, between the periodicity of $f$ and that of $f'$. That is, if $f$ is periodic, must $f'$ also be periodic? If $f'$ is periodic, must $f$ also be periodic?

## ✔ QUICK CHECK ANSWERS 2.5

**1.** (a) $\cos x$ (b) $-\sin x$ (c) $\sec^2 x$ (d) $\sec x \tan x$ **2.** $f'(x) = \cos^2 x - \sin^2 x$, $f'(\pi/3) = -\frac{1}{2}$

**3.** (a) $\dfrac{d}{dx}[\sin x]\Big|_{x=\pi/2} = 0$ (b) $\dfrac{d}{dx}[\csc x] = -\csc x \cot x$

# 2.6 THE CHAIN RULE

*In this section we will derive a formula that expresses the derivative of a composition $f \circ g$ in terms of the derivatives of $f$ and $g$. This formula will enable us to differentiate complicated functions using known derivatives of simpler functions.*

## DERIVATIVES OF COMPOSITIONS

Mike Brinson/Getty Images

*The cost of a car trip is a combination of fuel efficiency and the cost of gasoline.*

Suppose you are traveling to school in your car, which gets 20 miles per gallon of gasoline. The number of miles you can travel in your car without refueling is a function of the number of gallons of gas you have in the gas tank. In symbols, if $y$ is the number of miles you can travel and $u$ is the number of gallons of gas you have initially, then $y$ is a function of $u$, or $y = f(u)$. As you continue your travels, you note that your local service station is selling gasoline for \$4 per gallon. The number of gallons of gas you have initially is a function of the amount of money you spend for that gas. If $x$ is the number of dollars you spend on gas, then $u = g(x)$. Now 20 miles per gallon is the rate at which your mileage changes with respect to the amount of gasoline you use, so

$$f'(u) = \frac{dy}{du} = 20 \text{ miles per gallon}$$

Similarly, since gasoline costs \$4 per gallon, each dollar you spend will give you $1/4$ of a gallon of gas, and

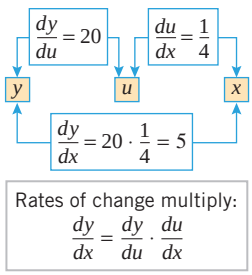
$$g'(x) = \frac{du}{dx} = \frac{1}{4} \text{ gallons per dollar}$$

Notice that the number of miles you can travel is also a function of the number of dollars you spend on gasoline. This fact is expressible as the composition of functions

$$y = f(u) = f(g(x))$$

You might be interested in how many miles you can travel per dollar, which is $dy/dx$. Intuition suggests that rates of change multiply in this case (see Figure 2.6.1), so

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = \frac{20 \text{ miles}}{1 \text{ gallon}} \cdot \frac{1 \text{ gallon}}{4 \text{ dollars}} = \frac{20 \text{ miles}}{4 \text{ dollars}} = 5 \text{ miles per dollar}$$



▲ **Figure 2.6.1**

The following theorem, the proof of which is given in Appendix D, formalizes the preceding ideas.

**2.6.1 THEOREM (*The Chain Rule*)** *If $g$ is differentiable at $x$ and $f$ is differentiable at $g(x)$, then the composition $f \circ g$ is differentiable at $x$. Moreover, if*

$$y = f(g(x)) \quad \text{and} \quad u = g(x)$$

*then $y = f(u)$ and*

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} \tag{1}$$

The name "chain rule" is appropriate because the desired derivative is obtained by a two-link "chain" of simpler derivatives.

Formula (1) is easy to remember because the left side is exactly what results if we "cancel" the $du$'s on the right side. This "canceling" device provides a good way of deducing the correct form of the chain rule when different variables are used. For example, if $w$ is a function of $x$ and $x$ is a function of $t$, then the chain rule takes the form

$$\frac{dw}{dt} = \frac{dw}{dx} \cdot \frac{dx}{dt}$$

**Example 1** Find $dy/dx$ if $y = \cos(x^3)$.

***Solution.*** Let $u = x^3$ and express $y$ as $y = \cos u$. Applying Formula (1) yields

$$\begin{aligned}\frac{dy}{dx} &= \frac{dy}{du} \cdot \frac{du}{dx} \\ &= \frac{d}{du}[\cos u] \cdot \frac{d}{dx}[x^3] \\ &= (-\sin u) \cdot (3x^2) \\ &= (-\sin(x^3)) \cdot (3x^2) = -3x^2 \sin(x^3)\end{aligned}$$ ◀

**Example 2** Find $dw/dt$ if $w = \tan x$ and $x = 4t^3 + t$.

***Solution.*** In this case the chain rule computations take the form

$$\begin{aligned}\frac{dw}{dt} &= \frac{dw}{dx} \cdot \frac{dx}{dt} \\ &= \frac{d}{dx}[\tan x] \cdot \frac{d}{dt}[4t^3 + t] \\ &= (\sec^2 x) \cdot (12t^2 + 1) \\ &= [\sec^2(4t^3 + t)] \cdot (12t^2 + 1) = (12t^2 + 1)\sec^2(4t^3 + t)\end{aligned}$$ ◀

## AN ALTERNATIVE VERSION OF THE CHAIN RULE

Formula (1) for the chain rule can be unwieldy in some problems because it involves so many variables. As you become more comfortable with the chain rule, you may want to dispense with writing out the dependent variables by expressing (1) in the form

Confirm that (2) is an alternative version of (1) by letting $y = f(g(x))$ and $u = g(x)$.

$$\frac{d}{dx}[f(g(x))] = (f \circ g)'(x) = f'(g(x))g'(x) \tag{2}$$

A convenient way to remember this formula is to call $f$ the "outside function" and $g$ the "inside function" in the composition $f(g(x))$ and then express (2) in words as:

*The derivative of $f(g(x))$ is the derivative of the outside function evaluated at the inside function times the derivative of the inside function.*

$$\frac{d}{dx}[f(g(x))] = \underbrace{f'(g(x))}_{\text{Derivative of the outside function evaluated at the inside function}} \cdot \underbrace{g'(x)}_{\text{Derivative of the inside function}}$$

▶ **Example 3** (*Example 1 revisited*) Find $h'(x)$ if $h(x) = \cos(x^3)$.

***Solution.*** We can think of $h$ as a composition $f(g(x))$ in which $g(x) = x^3$ is the inside function and $f(x) = \cos x$ is the outside function. Thus, Formula (2) yields

$$h'(x) = \underbrace{f'(g(x))}_{\text{Derivative of the outside function evaluated at the inside function}} \cdot \underbrace{g'(x)}_{\text{Derivative of the inside function}}$$

$$= f'(x^3) \cdot 3x^2$$

$$= -\sin(x^3) \cdot 3x^2 = -3x^2 \sin(x^3)$$

which agrees with the result obtained in Example 1. ◀

▶ **Example 4**

$$\frac{d}{dx}[\tan^2 x] = \frac{d}{dx}[(\tan x)^2] = \underbrace{(2\tan x)}_{\text{Derivative of the outside function evaluated at the inside function}} \cdot \underbrace{(\sec^2 x)}_{\text{Derivative of the inside function}} = 2\tan x \sec^2 x$$

$$\frac{d}{dx}[\sqrt{x^2+1}] = \underbrace{\frac{1}{2\sqrt{x^2+1}}}_{\text{Derivative of the outside function evaluated at the inside function}} \cdot \underbrace{2x}_{\text{Derivative of the inside function}} = \frac{x}{\sqrt{x^2+1}}$$

See Formula (6) of Section 2.3. ◀

## GENERALIZED DERIVATIVE FORMULAS

There is a useful third variation of the chain rule that strikes a middle ground between Formulas (1) and (2). If we let $u = g(x)$ in (2), then we can rewrite that formula as

$$\frac{d}{dx}[f(u)] = f'(u)\frac{du}{dx} \tag{3}$$

This result, called the ***generalized derivative formula*** for $f$, provides a way of using the derivative of $f(x)$ to produce the derivative of $f(u)$, where $u$ is a function of $x$. Table 2.6.1 gives some examples of this formula.

**Table 2.6.1**

GENERALIZED DERIVATIVE FORMULAS

$$\frac{d}{dx}[u^r] = ru^{r-1}\frac{du}{dx}$$

| | |
|---|---|
| $\frac{d}{dx}[\sin u] = \cos u \frac{du}{dx}$ | $\frac{d}{dx}[\cos u] = -\sin u \frac{du}{dx}$ |
| $\frac{d}{dx}[\tan u] = \sec^2 u \frac{du}{dx}$ | $\frac{d}{dx}[\cot u] = -\csc^2 u \frac{du}{dx}$ |
| $\frac{d}{dx}[\sec u] = \sec u \tan u \frac{du}{dx}$ | $\frac{d}{dx}[\csc u] = -\csc u \cot u \frac{du}{dx}$ |

**▶ Example 5** Find

(a) $\dfrac{d}{dx}[\sin(2x)]$ (b) $\dfrac{d}{dx}[\tan(x^2+1)]$ (c) $\dfrac{d}{dx}\left[\sqrt{x^3+\csc x}\right]$

(d) $\dfrac{d}{dx}[x^2-x+2]^{3/4}$ (e) $\dfrac{d}{dx}\left[(1+x^5\cot x)^{-8}\right]$

***Solution (a).*** Taking $u = 2x$ in the generalized derivative formula for $\sin u$ yields

$$\frac{d}{dx}[\sin(2x)] = \frac{d}{dx}[\sin u] = \cos u\frac{du}{dx} = \cos 2x \cdot \frac{d}{dx}[2x] = \cos 2x \cdot 2 = 2\cos 2x$$

***Solution (b).*** Taking $u = x^2 + 1$ in the generalized derivative formula for $\tan u$ yields

$$\begin{aligned}\frac{d}{dx}[\tan(x^2+1)] &= \frac{d}{dx}[\tan u] = \sec^2 u\frac{du}{dx}\\ &= \sec^2(x^2+1)\cdot\frac{d}{dx}[x^2+1] = \sec^2(x^2+1)\cdot 2x\\ &= 2x\sec^2(x^2+1)\end{aligned}$$

***Solution (c).*** Taking $u = x^3 + \csc x$ in the generalized derivative formula for $\sqrt{u}$ yields

$$\begin{aligned}\frac{d}{dx}\left[\sqrt{x^3+\csc x}\right] &= \frac{d}{dx}[\sqrt{u}] = \frac{1}{2\sqrt{u}}\frac{du}{dx} = \frac{1}{2\sqrt{x^3+\csc x}}\cdot\frac{d}{dx}[x^3+\csc x]\\ &= \frac{1}{2\sqrt{x^3+\csc x}}\cdot(3x^2-\csc x\cot x) = \frac{3x^2-\csc x\cot x}{2\sqrt{x^3+\csc x}}\end{aligned}$$

***Solution (d).*** Taking $u = x^2 - x + 2$ in the generalized derivative formula for $u^{3/4}$ yields

$$\begin{aligned}\frac{d}{dx}[x^2-x+2]^{3/4} &= \frac{d}{dx}[u^{3/4}] = \frac{3}{4}u^{-1/4}\frac{du}{dx}\\ &= \frac{3}{4}(x^2-x+2)^{-1/4}\cdot\frac{d}{dx}[x^2-x+2]\\ &= \frac{3}{4}(x^2-x+2)^{-1/4}(2x-1)\end{aligned}$$

***Solution (e).*** Taking $u = 1 + x^5\cot x$ in the generalized derivative formula for $u^{-8}$ yields

$$\begin{aligned}\frac{d}{dx}\left[(1+x^5\cot x)^{-8}\right] &= \frac{d}{dx}[u^{-8}] = -8u^{-9}\frac{du}{dx}\\ &= -8(1+x^5\cot x)^{-9}\cdot\frac{d}{dx}[1+x^5\cot x]\\ &= -8(1+x^5\cot x)^{-9}\cdot\left[x^5(-\csc^2 x)+5x^4\cot x\right]\\ &= (8x^5\csc^2 x - 40x^4\cot x)(1+x^5\cot x)^{-9}\end{aligned}$$ ◀

Sometimes you will have to make adjustments in notation or apply the chain rule more than once to calculate a derivative.

**▶ Example 6** Find

(a) $\dfrac{d}{dx}\left[\sin(\sqrt{1+\cos x})\right]$ (b) $\dfrac{d\mu}{dt}$ if $\mu = \sec\sqrt{\omega t}$ ($\omega$ constant)

***Solution (a).*** Taking $u = \sqrt{1+\cos x}$ in the generalized derivative formula for $\sin u$ yields

$$\frac{d}{dx}\left[\sin(\sqrt{1+\cos x})\right] = \frac{d}{dx}[\sin u] = \cos u \frac{du}{dx}$$

$$= \cos(\sqrt{1+\cos x}) \cdot \frac{d}{dx}\left[\sqrt{1+\cos x}\right]$$

$$= \cos(\sqrt{1+\cos x}) \cdot \frac{-\sin x}{2\sqrt{1+\cos x}}$$

We used the generalized derivative formula for $\sqrt{u}$ with $u = 1+\cos x$.

$$= -\frac{\sin x \cos(\sqrt{1+\cos x})}{2\sqrt{1+\cos x}}$$

***Solution (b).***

$$\frac{d\mu}{dt} = \frac{d}{dt}[\sec\sqrt{\omega t}] = \sec\sqrt{\omega t}\tan\sqrt{\omega t}\frac{d}{dt}[\sqrt{\omega t}]$$

We used the generalized derivative formula for $\sec u$ with $u = \sqrt{\omega t}$.

$$= \sec\sqrt{\omega t}\tan\sqrt{\omega t}\frac{\omega}{2\sqrt{\omega t}}$$

We used the generalized derivative formula for $\sqrt{u}$ with $u = \omega t$. ◀

## DIFFERENTIATING USING COMPUTER ALGEBRA SYSTEMS

Even with the chain rule and other differentiation rules, some derivative computations can be tedious to perform. For complicated derivatives, engineers and scientists often use computer algebra systems such as *Mathematica*, *Maple*, or *Sage*. For example, although we have all the mathematical tools to compute

$$\frac{d}{dx}\left[\frac{(x^2+1)^{10}\sin^3(\sqrt{x})}{\sqrt{1+\csc x}}\right] \tag{4}$$

by hand, the computation is sufficiently involved that it may be more efficient (and less error-prone) to use a computer algebra system.

**TECHNOLOGY MASTERY**

If you have a CAS, use it to perform the differentiation in (4).

## QUICK CHECK EXERCISES 2.6 (See page 181 for answers.)

1. The chain rule states that the derivative of the composition of two functions is the derivative of the _____ function evaluated at the _____ function times the derivative of the _____ function.
2. If $y$ is a differentiable function of $u$, and $u$ is a differentiable function of $x$, then
$$\frac{dy}{dx} = _____ \cdot _____$$
3. Find $dy/dx$.
   (a) $y = (x^2+5)^{10}$ (b) $y = \sqrt{1+6x}$
4. Find $dy/dx$.
   (a) $y = \sin(3x+2)$ (b) $y = (x^2\tan x)^4$
5. Suppose that $f(2) = 3$, $f'(2) = 4$, $g(3) = 6$, and $g'(3) = -5$. Evaluate
   (a) $h'(2)$, where $h(x) = g(f(x))$
   (b) $k'(3)$, where $k(x) = f\left(\frac{1}{3}g(x)\right)$.

## EXERCISE SET 2.6 Graphing Utility C CAS

1. Given that
$$f'(0) = 2,\ g(0) = 0 \quad \text{and} \quad g'(0) = 3$$
find $(f\circ g)'(0)$.
2. Given that
$$f'(9) = 5,\ g(2) = 9 \quad \text{and} \quad g'(2) = -3$$
find $(f\circ g)'(2)$.
3. Let $f(x) = x^5$ and $g(x) = 2x-3$.
   (a) Find $(f\circ g)(x)$ and $(f\circ g)'(x)$.
   (b) Find $(g\circ f)(x)$ and $(g\circ f)'(x)$.
4. Let $f(x) = 5\sqrt{x}$ and $g(x) = 4+\cos x$.
   (a) Find $(f\circ g)(x)$ and $(f\circ g)'(x)$.
   (b) Find $(g\circ f)(x)$ and $(g\circ f)'(x)$.

**FOCUS ON CONCEPTS**

**5.** Given the following table of values, find the indicated derivatives in parts (a) and (b).

| $x$ | $f(x)$ | $f'(x)$ | $g(x)$ | $g'(x)$ |
|---|---|---|---|---|
| 3 | 5 | −2 | 5 | 7 |
| 5 | 3 | −1 | 12 | 4 |

(a) $F'(3)$, where $F(x) = f(g(x))$
(b) $G'(3)$, where $G(x) = g(f(x))$

**6.** Given the following table of values, find the indicated derivatives in parts (a) and (b).

| $x$ | $f(x)$ | $f'(x)$ | $g(x)$ | $g'(x)$ |
|---|---|---|---|---|
| −1 | 2 | 3 | 2 | −3 |
| 2 | 0 | 4 | 1 | −5 |

(a) $F'(-1)$, where $F(x) = f(g(x))$
(b) $G'(-1)$, where $G(x) = g(f(x))$

**7–26** Find $f'(x)$. ■

**7.** $f(x) = (x^3 + 2x)^{37}$

**8.** $f(x) = (3x^2 + 2x - 1)^6$

**9.** $f(x) = \left(x^3 - \dfrac{7}{x}\right)^{-2}$

**10.** $f(x) = \dfrac{1}{(x^5 - x + 1)^9}$

**11.** $f(x) = \dfrac{4}{(3x^2 - 2x + 1)^3}$

**12.** $f(x) = \sqrt{x^3 - 2x + 5}$

**13.** $f(x) = \sqrt{4 + \sqrt{3x}}$

**14.** $f(x) = \sqrt[3]{12 + \sqrt{x}}$

**15.** $f(x) = \sin\left(\dfrac{1}{x^2}\right)$

**16.** $f(x) = \tan\sqrt{x}$

**17.** $f(x) = 4\cos^5 x$

**18.** $f(x) = 4x + 5\sin^4 x$

**19.** $f(x) = \cos^2(3\sqrt{x})$

**20.** $f(x) = \tan^4(x^3)$

**21.** $f(x) = 2\sec^2(x^7)$

**22.** $f(x) = \cos^3\left(\dfrac{x}{x+1}\right)$

**23.** $f(x) = \sqrt{\cos(5x)}$

**24.** $f(x) = \sqrt{3x - \sin^2(4x)}$

**25.** $f(x) = [x + \csc(x^3 + 3)]^{-3}$

**26.** $f(x) = [x^4 - \sec(4x^2 - 2)]^{-4}$

**27–40** Find $dy/dx$. ■

**27.** $y = x^3\sin^2(5x)$

**28.** $y = \sqrt{x}\tan^3(\sqrt{x})$

**29.** $y = x^5\sec(1/x)$

**30.** $y = \dfrac{\sin x}{\sec(3x+1)}$

**31.** $y = \cos(\cos x)$

**32.** $y = \sin(\tan 3x)$

**33.** $y = \cos^3(\sin 2x)$

**34.** $y = \dfrac{1 + \csc(x^2)}{1 - \cot(x^2)}$

**35.** $y = (5x + 8)^7\left(1 - \sqrt{x}\right)^6$

**36.** $y = (x^2 + x)^5\sin^8 x$

**37.** $y = \left(\dfrac{x-5}{2x+1}\right)^3$

**38.** $y = \left(\dfrac{1+x^2}{1-x^2}\right)^{17}$

**39.** $y = \dfrac{(2x+3)^3}{(4x^2-1)^8}$

**40.** $y = [1 + \sin^3(x^5)]^{12}$

C **41–42** Use a CAS to find $dy/dx$. ■

**41.** $y = [x\sin 2x + \tan^4(x^7)]^5$

**42.** $y = \tan^4\left(2 + \dfrac{(7-x)\sqrt{3x^2+5}}{x^3 + \sin x}\right)$

**43–50** Find an equation for the tangent line to the graph at the specified value of $x$. ■

**43.** $y = x\cos 3x,\ x = \pi$

**44.** $y = \sin(1 + x^3),\ x = -3$

**45.** $y = \sec^3\left(\dfrac{\pi}{2} - x\right),\ x = -\dfrac{\pi}{2}$

**46.** $y = \left(x - \dfrac{1}{x}\right)^3,\ x = 2$

**47.** $y = \tan(4x^2),\ x = \sqrt{\pi}$

**48.** $y = 3\cot^4 x,\ x = \dfrac{\pi}{4}$

**49.** $y = x^2\sqrt{5 - x^2},\ x = 1$

**50.** $y = \dfrac{x}{\sqrt{1 - x^2}},\ x = 0$

**51–54** Find $d^2y/dx^2$. ■

**51.** $y = x\cos(5x) - \sin^2 x$

**52.** $y = \sin(3x^2)$

**53.** $y = \dfrac{1+x}{1-x}$

**54.** $y = x\tan\left(\dfrac{1}{x}\right)$

**55–58** Find the indicated derivative. ■

**55.** $y = \cot^3(\pi - \theta)$; find $\dfrac{dy}{d\theta}$.

**56.** $\lambda = \left(\dfrac{au+b}{cu+d}\right)^6$; find $\dfrac{d\lambda}{du}$ ($a, b, c, d$ constants).

**57.** $\dfrac{d}{d\omega}[a\cos^2\pi\omega + b\sin^2\pi\omega]$ ($a, b$ constants)

**58.** $x = \csc^2\left(\dfrac{\pi}{3} - y\right)$; find $\dfrac{dx}{dy}$.

**59.** (a) Use a graphing utility to obtain the graph of the function $f(x) = x\sqrt{4 - x^2}$.
(b) Use the graph in part (a) to make a rough sketch of the graph of $f'$.
(c) Find $f'(x)$, and then check your work in part (b) by using the graphing utility to obtain the graph of $f'$.
(d) Find the equation of the tangent line to the graph of $f$ at $x = 1$, and graph $f$ and the tangent line together.

**60.** (a) Use a graphing utility to obtain the graph of the function $f(x) = \sin x^2\cos x$ over the interval $[-\pi/2, \pi/2]$.
(b) Use the graph in part (a) to make a rough sketch of the graph of $f'$ over the interval.
(c) Find $f'(x)$, and then check your work in part (b) by using the graphing utility to obtain the graph of $f'$ over the interval.
(d) Find the equation of the tangent line to the graph of $f$ at $x = 1$, and graph $f$ and the tangent line together over the interval.

**61–64 True–False** Determine whether the statement is true or false. Explain your answer. ■

**61.** If $y = f(x)$, then $\dfrac{d}{dx}[\sqrt{y}] = \sqrt{f'(x)}$.

**62.** If $y = f(u)$ and $u = g(x)$, then $dy/dx = f'(x) \cdot g'(x)$.

**63.** If $y = \cos[g(x)]$, then $dy/dx = -\sin[g'(x)]$.

**64.** If $y = \sin^3(3x^3)$, then $dy/dx = 27x^2 \sin^2(3x^3)\cos(3x^3)$.

**65.** If an object suspended from a spring is displaced vertically from its equilibrium position by a small amount and released, and if the air resistance and the mass of the spring are ignored, then the resulting oscillation of the object is called ***simple harmonic motion***. Under appropriate conditions the displacement $y$ from equilibrium in terms of time $t$ is given by

$$y = A\cos\omega t$$

where $A$ is the initial displacement at time $t = 0$, and $\omega$ is a constant that depends on the mass of the object and the stiffness of the spring (see the accompanying figure). The constant $|A|$ is called the ***amplitude*** of the motion and $\omega$ the ***angular frequency***.

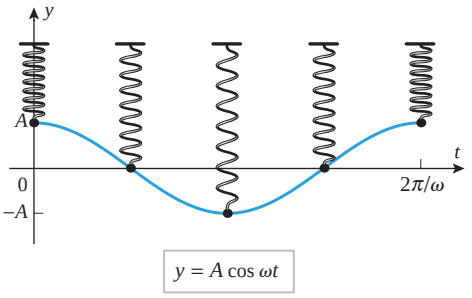
(a) Show that

$$\frac{d^2y}{dt^2} = -\omega^2 y$$

(b) The ***period*** $T$ is the time required to make one complete oscillation. Show that $T = 2\pi/\omega$.

(c) The ***frequency*** $f$ of the vibration is the number of oscillations per unit time. Find $f$ in terms of the period $T$.

(d) Find the amplitude, period, and frequency of an object that is executing simple harmonic motion given by $y = 0.6\cos 15t$, where $t$ is in seconds and $y$ is in centimeters.



▲ **Figure Ex-65**

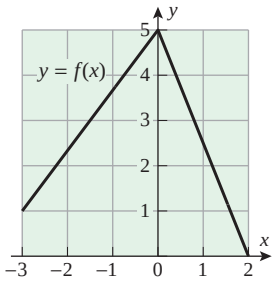
**66.** Find the value of the constant $A$ so that $y = A\sin 3t$ satisfies the equation

$$\frac{d^2y}{dt^2} + 2y = 4\sin 3t$$

**FOCUS ON CONCEPTS**

**67.** Use the graph of the function $f$ in the accompanying figure to evaluate

$$\frac{d}{dx}\left[\sqrt{x + f(x)}\right]\Big|_{x=-1}$$



◀ **Figure Ex-67**

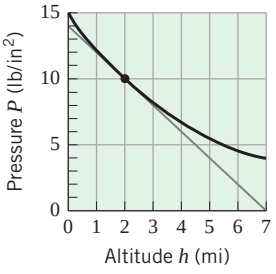
**68.** Using the function $f$ in Exercise 67, evaluate

$$\frac{d}{dx}[f(2\sin x)]\Big|_{x=\pi/6}$$

**69.** The accompanying figure shows the graph of atmospheric pressure $p$ (lb/in$^2$) versus the altitude $h$ (mi) above sea level.

(a) From the graph and the tangent line at $h = 2$ shown on the graph, estimate the values of $p$ and $dp/dh$ at an altitude of 2 mi.

(b) If the altitude of a space vehicle is increasing at the rate of 0.3 mi/s at the instant when it is 2 mi above sea level, how fast is the pressure changing with time at this instant?



◀ **Figure Ex-69**

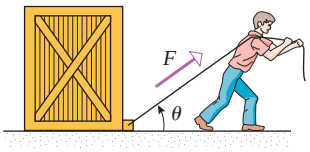
**70.** The force $F$ (in pounds) acting at an angle $\theta$ with the horizontal that is needed to drag a crate weighing $W$ pounds along a horizontal surface at a constant velocity is given by

$$F = \frac{\mu W}{\cos\theta + \mu\sin\theta}$$

where $\mu$ is a constant called the ***coefficient of sliding friction*** between the crate and the surface (see the accompanying figure). Suppose that the crate weighs 150 lb and that $\mu = 0.3$.

(a) Find $dF/d\theta$ when $\theta = 30°$. Express the answer in units of pounds/degree.

(b) Find $dF/dt$ when $\theta = 30°$ if $\theta$ is decreasing at the rate of $0.5°/\text{s}$ at this instant.



◀ **Figure Ex-70**

**71.** Recall that

$$\frac{d}{dx}(|x|) = \begin{cases} 1, & x > 0 \\ -1, & x < 0 \end{cases}$$

Use this result and the chain rule to find

$$\frac{d}{dx}(|\sin x|)$$

for nonzero $x$ in the interval $(-\pi, \pi)$.

**72.** Use the derivative formula for $\sin x$ and the identity

$$\cos x = \sin\left(\frac{\pi}{2} - x\right)$$

to obtain the derivative formula for $\cos x$.

**73.** Let

$$f(x) = \begin{cases} x \sin\dfrac{1}{x}, & x \neq 0 \\ 0, & x = 0 \end{cases}$$

(a) Show that $f$ is continuous at $x = 0$.
(b) Use Definition 2.2.1 to show that $f'(0)$ does not exist.
(c) Find $f'(x)$ for $x \neq 0$.
(d) Determine whether $\lim_{x \to 0} f'(x)$ exists.

**74.** Let

$$f(x) = \begin{cases} x^2 \sin\dfrac{1}{x}, & x \neq 0 \\ 0, & x = 0 \end{cases}$$

(a) Show that $f$ is continuous at $x = 0$.
(b) Use Definition 2.2.1 to find $f'(0)$.
(c) Find $f'(x)$ for $x \neq 0$.
(d) Show that $f'$ is not continuous at $x = 0$.

**75.** Given the following table of values, find the indicated derivatives in parts (a) and (b).

| $x$ | $f(x)$ | $f'(x)$ |
|---|---|---|
| 2 | 1 | 7 |
| 8 | 5 | −3 |

(a) $g'(2)$, where $g(x) = [f(x)]^3$
(b) $h'(2)$, where $h(x) = f(x^3)$

**76.** Given that $f'(x) = \sqrt{3x + 4}$ and $g(x) = x^2 - 1$, find $F'(x)$ if $F(x) = f(g(x))$.

**77.** Given that $f'(x) = \dfrac{x}{x^2 + 1}$ and $g(x) = \sqrt{3x - 1}$, find $F'(x)$ if $F(x) = f(g(x))$.

**78.** Find $f'(x^2)$ if $\dfrac{d}{dx}[f(x^2)] = x^2$.

**79.** Find $\dfrac{d}{dx}[f(x)]$ if $\dfrac{d}{dx}[f(3x)] = 6x$.

**80.** Recall that a function $f$ is ***even*** if $f(-x) = f(x)$ and ***odd*** if $f(-x) = -f(x)$, for all $x$ in the domain of $f$. Assuming that $f$ is differentiable, prove:
(a) $f'$ is odd if $f$ is even
(b) $f'$ is even if $f$ is odd.

**81.** Draw some pictures to illustrate the results in Exercise 80, and write a paragraph that gives an informal explanation of why the results are true.

**82.** Let $y = f_1(u)$, $u = f_2(v)$, $v = f_3(w)$, and $w = f_4(x)$. Express $dy/dx$ in terms of $dy/du$, $dw/dx$, $du/dv$, and $dv/dw$.

**83.** Find a formula for

$$\frac{d}{dx}[f(g(h(x)))]$$

**84.** **Writing** The "co" in "cosine" comes from "complementary," since the cosine of an angle is the sine of the complementary angle, and vice versa:

$$\cos x = \sin\left(\frac{\pi}{2} - x\right) \quad \text{and} \quad \sin x = \cos\left(\frac{\pi}{2} - x\right)$$

Suppose that we define a function $g$ to be a *cofunction* of a function $f$ if

$$g(x) = f\left(\frac{\pi}{2} - x\right) \quad \text{for all } x$$

Thus, cosine and sine are cofunctions of each other, as are cotangent and tangent, and also cosecant and secant. If $g$ is the cofunction of $f$, state a formula that relates $g'$ and the cofunction of $f'$. Discuss how this relationship is exhibited by the derivatives of the cosine, cotangent, and cosecant functions.

## ✔ QUICK CHECK ANSWERS 2.6

**1.** outside; inside; inside **2.** $\dfrac{dy}{du} \cdot \dfrac{du}{dx}$ **3.** (a) $10(x^2 + 5)^9 \cdot 2x = 20x(x^2 + 5)^9$ (b) $\dfrac{1}{2\sqrt{1 + 6x}} \cdot 6 = \dfrac{3}{\sqrt{1 + 6x}}$

**4.** (a) $3\cos(3x + 2)$ (b) $4(x^2 \tan x)^3(2x \tan x + x^2 \sec^2 x)$ **5.** (a) $g'(f(2))f'(2) = -20$ (b) $f'\left(\dfrac{1}{3}g(3)\right) \cdot \dfrac{1}{3}g'(3) = -\dfrac{20}{3}$

## CHAPTER 2 REVIEW EXERCISES

Graphing Utility CAS

**1.** Explain the difference between average and instantaneous rates of change, and discuss how they are calculated.

**2.** In parts (a)–(d), use the function $y = \frac{1}{2}x^2$.

(a) Find the average rate of change of $y$ with respect to $x$ over the interval $[3, 4]$.
(b) Find the instantaneous rate of change of $y$ with respect to $x$ at $x = 3$.

(cont.)

(c) Find the instantaneous rate of change of $y$ with respect to $x$ at a general $x$-value.

(d) Sketch the graph of $y = \frac{1}{2}x^2$ together with the secant line whose slope is given by the result in part (a), and indicate graphically the slope of the tangent line that corresponds to the result in part (b).

**3.** Complete each part for the function $f(x) = x^2 + 1$.

(a) Find the slope of the tangent line to the graph of $f$ at a general $x$-value.

(b) Find the slope of the tangent line to the graph of $f$ at $x = 2$.

**4.** A car is traveling on a straight road that is 120 mi long. For the first 100 mi the car travels at an average velocity of 50 mi/h. Show that no matter how fast the car travels for the final 20 mi it cannot bring the average velocity up to 60 mi/h for the entire trip.

**5.** At time $t = 0$ a car moves into the passing lane to pass a slow-moving truck. The average velocity of the car from $t = 1$ to $t = 1 + h$ is

$$v_{\text{ave}} = \frac{3(h+1)^{2.5} + 580h - 3}{10h}$$

Estimate the instantaneous velocity of the car at $t = 1$, where time is in seconds and distance is in feet.

**6.** A skydiver jumps from an airplane. Suppose that the distance she falls during the first $t$ seconds before her parachute opens is $s(t) = 976((0.835)^t - 1) + 176t$, where $s$ is in feet. Graph $s$ versus $t$ for $0 \le t \le 20$, and use your graph to estimate the instantaneous velocity at $t = 15$.

**7.** A particle moves on a line away from its initial position so that after $t$ hours it is $s = 3t^2 + t$ miles from its initial position.

(a) Find the average velocity of the particle over the interval $[1, 3]$.

(b) Find the instantaneous velocity at $t = 1$.

**8.** State the definition of a derivative, and give two interpretations of it.

**9.** Use the definition of a derivative to find $dy/dx$, and check your answer by calculating the derivative using appropriate derivative formulas.

(a) $y = \sqrt{9 - 4x}$ (b) $y = \dfrac{x}{x+1}$

**10.** Suppose that $f(x) = \begin{cases} x^2 - 1, & x \le 1 \\ k(x-1), & x > 1. \end{cases}$

For what values of $k$ is $f$

(a) continuous? (b) differentiable?

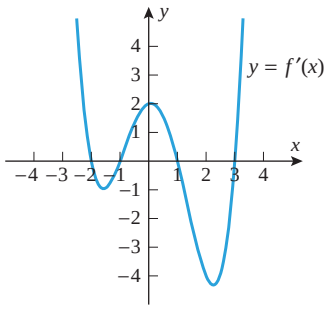
**11.** The accompanying figure shows the graph of $y = f'(x)$ for an unspecified function $f$.

(a) For what values of $x$ does the curve $y = f(x)$ have a horizontal tangent line?

(b) Over what intervals does the curve $y = f(x)$ have tangent lines with positive slope?

(c) Over what intervals does the curve $y = f(x)$ have tangent lines with negative slope?

(d) Given that $g(x) = f(x)\sin x$, find $g''(0)$.



◀ **Figure Ex-11**

**12.** Sketch the graph of a function $f$ for which $f(0) = 1$, $f'(0) = 0$, $f'(x) > 0$ if $x < 0$, and $f'(x) < 0$ if $x > 0$.

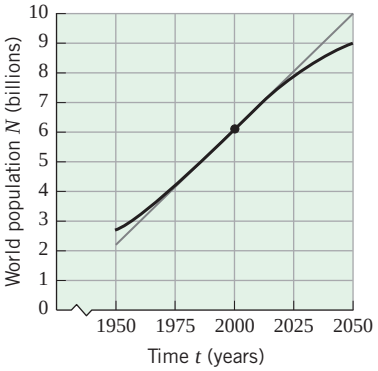
**13.** According to the U.S. Bureau of the Census, the estimated and projected midyear world population, $N$, in billions for the years 1950, 1975, 2000, 2025, and 2050 was 2.555, 4.088, 6.080, 7.841, and 9.104, respectively. Although the increase in population is not a continuous function of the time $t$, we can apply the ideas in this section if we are willing to approximate the graph of $N$ versus $t$ by a continuous curve, as shown in the accompanying figure.

(a) Use the tangent line at $t = 2000$ shown in the figure to approximate the value of $dN/dt$ there. Interpret your result as a rate of change.

(b) The instantaneous ***growth rate*** is defined as

$$\frac{dN/dt}{N}$$

Use your answer to part (a) to approximate the instantaneous growth rate at the start of the year 2000. Express the result as a percentage and include the proper units.



◀ **Figure Ex-13**

**14.** Use a graphing utility to graph the function

$$f(x) = |x^4 - x - 1| - x$$

and estimate the values of $x$ where the derivative of this function does not exist.

C **15–18** (a) Use a CAS to find $f'(x)$ via Definition 2.2.1; (b) check the result by finding the derivative by hand; (c) use the CAS to find $f''(x)$. ■

**15.** $f(x) = x^2 \sin x$

**16.** $f(x) = \sqrt{x} + \cos^2 x$

**17.** $f(x) = \dfrac{2x^2 - x + 5}{3x + 2}$

**18.** $f(x) = \dfrac{\tan x}{1 + x^2}$

**19.** The amount of water in a tank $t$ minutes after it has started to drain is given by $W = 100(t - 15)^2$ gal.
(a) At what rate is the water running out at the end of 5 min?
(b) What is the average rate at which the water flows out during the first 5 min?

**20.** Use the formula $V = l^3$ for the volume of a cube of side $l$ to find
(a) the average rate at which the volume of a cube changes with $l$ as $l$ increases from $l = 2$ to $l = 4$
(b) the instantaneous rate at which the volume of a cube changes with $l$ when $l = 5$.

**21–22** Zoom in on the graph of $f$ on an interval containing $x = x_0$ until the graph looks like a straight line. Estimate the slope of this line and then check your answer by finding the exact value of $f'(x_0)$. ■

**21.** (a) $f(x) = x^2 - 1,\ x_0 = 1.8$
(b) $f(x) = \dfrac{x^2}{x - 2},\ x_0 = 3.5$

**22.** (a) $f(x) = x^3 - x^2 + 1,\ x_0 = 2.3$
(b) $f(x) = \dfrac{x}{x^2 + 1},\ x_0 = -0.5$

**23.** Suppose that a function $f$ is differentiable at $x = 1$ and

$$\lim_{h \to 0} \frac{f(1 + h)}{h} = 5$$

Find $f(1)$ and $f'(1)$.

**24.** Suppose that a function $f$ is differentiable at $x = 2$ and

$$\lim_{x \to 2} \frac{x^3 f(x) - 24}{x - 2} = 28$$

Find $f(2)$ and $f'(2)$.

**25.** Find the equations of all lines through the origin that are tangent to the curve $y = x^3 - 9x^2 - 16x$.

**26.** Find all values of $x$ for which the tangent line to the curve $y = 2x^3 - x^2$ is perpendicular to the line $x + 4y = 10$.

**27.** Let $f(x) = x^2$. Show that for any distinct values of $a$ and $b$, the slope of the tangent line to $y = f(x)$ at $x = \frac{1}{2}(a + b)$ is equal to the slope of the secant line through the points $(a, a^2)$ and $(b, b^2)$. Draw a picture to illustrate this result.

**28.** In each part, evaluate the expression given that $f(1) = 1$, $g(1) = -2$, $f'(1) = 3$, and $g'(1) = -1$.
(a) $\dfrac{d}{dx}[f(x)g(x)]\Big|_{x=1}$ (b) $\dfrac{d}{dx}\left[\dfrac{f(x)}{g(x)}\right]\Big|_{x=1}$
(c) $\dfrac{d}{dx}\left[\sqrt{f(x)}\right]\Big|_{x=1}$ (d) $\dfrac{d}{dx}[f(1)g'(1)]$

**29–32** Find $f'(x)$. ■

**29.** (a) $f(x) = x^8 - 3\sqrt{x} + 5x^{-3}$
(b) $f(x) = (2x + 1)^{101}(5x^2 - 7)$

**30.** (a) $f(x) = \sin x + 2\cos^3 x$
(b) $f(x) = (1 + \sec x)(x^2 - \tan x)$

**31.** (a) $f(x) = \sqrt{3x + 1}(x - 1)^2$
(b) $f(x) = \left(\dfrac{3x + 1}{x^2}\right)^3$

**32.** (a) $f(x) = \cot\left(\dfrac{\csc 2x}{x^3 + 5}\right)$ (b) $f(x) = \dfrac{1}{2x + \sin^3 x}$

**33–34** Find the values of $x$ at which the curve $y = f(x)$ has a horizontal tangent line. ■

**33.** $f(x) = (2x + 7)^6(x - 2)^5$

**34.** $f(x) = \dfrac{(x - 3)^4}{x^2 + 2x}$

**35.** Find all lines that are simultaneously tangent to the graph of $y = x^2 + 1$ and to the graph of $y = -x^2 - 1$.

**36.** (a) Let $n$ denote an even positive integer. Generalize the result of Exercise 35 by finding all lines that are simultaneously tangent to the graph of $y = x^n + n - 1$ and to the graph of $y = -x^n - n + 1$.
(b) Let $n$ denote an odd positive integer. Are there any lines that are simultaneously tangent to the graph of $y = x^n + n - 1$ and to the graph of $y = -x^n - n + 1$? Explain.

**37.** Find all values of $x$ for which the line that is tangent to $y = 3x - \tan x$ is parallel to the line $y - x = 2$.

**38.** Approximate the values of $x$ at which the tangent line to the graph of $y = x^3 - \sin x$ is horizontal.

**39.** Suppose that $f(x) = M \sin x + N \cos x$ for some constants $M$ and $N$. If $f(\pi/4) = 3$ and $f'(\pi/4) = 1$, find an equation for the tangent line to $y = f(x)$ at $x = 3\pi/4$.

**40.** Suppose that $f(x) = M \tan x + N \sec x$ for some constants $M$ and $N$. If $f(\pi/4) = 2$ and $f'(\pi/4) = 0$, find an equation for the tangent line to $y = f(x)$ at $x = 0$.

**41.** Suppose that $f'(x) = 2x \cdot f(x)$ and $f(2) = 5$.
(a) Find $g'(\pi/3)$ if $g(x) = f(\sec x)$.
(b) Find $h'(2)$ if $h(x) = [f(x)/(x - 1)]^4$.

## CHAPTER 2 MAKING CONNECTIONS

**1.** Suppose that $f$ is a function with the properties (i) $f$ is differentiable everywhere, (ii) $f(x+y) = f(x)f(y)$ for all values of $x$ and $y$, (iii) $f(0) \neq 0$, and (iv) $f'(0) = 1$.
   (a) Show that $f(0) = 1$. [*Hint:* Consider $f(0+0)$.]
   (b) Show that $f(x) > 0$ for all values of $x$. [*Hint:* First show that $f(x) \neq 0$ for any $x$ by considering $f(x-x)$.]
   (c) Use the definition of derivative (Definition 2.2.1) to show that $f'(x) = f(x)$ for all values of $x$.

**2.** Suppose that $f$ and $g$ are functions each of which has the properties (i)–(iv) in Exercise 1.
   (a) Show that $y = f(2x)$ satisfies the equation $y' = 2y$ in two ways: using property (ii), and by directly applying the chain rule (Theorem 2.6.1).
   (b) If $k$ is any constant, show that $y = f(kx)$ satisfies the equation $y' = ky$.
   (c) Find a value of $k$ such that $y = f(x)g(x)$ satisfies the equation $y' = ky$.
   (d) If $h = f/g$, find $h'(x)$. Make a conjecture about the relationship between $f$ and $g$.

**3.** (a) Apply the product rule (Theorem 2.4.1) twice to show that if $f$, $g$, and $h$ are differentiable functions, then $f \cdot g \cdot h$ is differentiable and

$$(f \cdot g \cdot h)' = f' \cdot g \cdot h + f \cdot g' \cdot h + f \cdot g \cdot h'$$

   (b) Suppose that $f$, $g$, $h$, and $k$ are differentiable functions. Derive a formula for $(f \cdot g \cdot h \cdot k)'$.
   (c) Based on the result in part (a), make a conjecture about a formula differentiating a product of $n$ functions. Prove your formula using induction.

**4.** (a) Apply the quotient rule (Theorem 2.4.2) twice to show that if $f$, $g$, and $h$ are differentiable functions, then $(f/g)/h$ is differentiable where it is defined and

$$[(f/g)/h]' = \frac{f' \cdot g \cdot h - f \cdot g' \cdot h - f \cdot g \cdot h'}{g^2 h^2}$$

   (b) Derive the derivative formula of part (a) by first simplifying $(f/g)/h$ and then applying the quotient and product rules.
   (c) Apply the quotient rule (Theorem 2.4.2) twice to derive a formula for $[f/(g/h)]'$.
   (d) Derive the derivative formula of part (c) by first simplifying $f/(g/h)$ and then applying the quotient and product rules.

**5.** Assume that $h(x) = f(x)/g(x)$ is differentiable. Derive the quotient rule formula for $h'(x)$ (Theorem 2.4.2) in two ways:
   (a) Write $h(x) = f(x) \cdot [g(x)]^{-1}$ and use the product and chain rules (Theorems 2.4.1 and 2.6.1) to differentiate $h$.
   (b) Write $f(x) = h(x) \cdot g(x)$ and use the product rule to derive a formula for $h'(x)$.

## EXPANDING THE CALCULUS HORIZON

To learn how derivatives can be used in the field of robotics, see the module entitled **Robotics** at:

www.wiley.com/college/anton

# 3 TOPICS IN DIFFERENTIATION

Craig Lovell/Corbis Images

*The growth and decline of animal populations and natural resources can be modeled using basic functions studied in calculus.*

We begin this chapter by extending the process of differentiation to functions that are either difficult or impossible to differentiate directly. We will discuss a combination of direct and indirect methods of differentiation that will allow us to develop a number of new derivative formulas that include the derivatives of logarithmic, exponential, and inverse trigonometric functions. Later in the chapter, we will consider some applications of the derivative. These will include ways in which different rates of change can be related as well as the use of linear functions to approximate nonlinear functions. Finally, we will discuss L'Hôpital's rule, a powerful tool for evaluating limits.

## 3.1 IMPLICIT DIFFERENTIATION

*Up to now we have been concerned with differentiating functions that are given by equations of the form $y = f(x)$. In this section we will consider methods for differentiating functions for which it is inconvenient or impossible to express them in this form.*

### FUNCTIONS DEFINED EXPLICITLY AND IMPLICITLY

An equation of the form $y = f(x)$ is said to define $y$ ***explicitly*** as a function of $x$ because the variable $y$ appears alone on one side of the equation and does not appear at all on the other side. However, sometimes functions are defined by equations in which $y$ is not alone on one side; for example, the equation

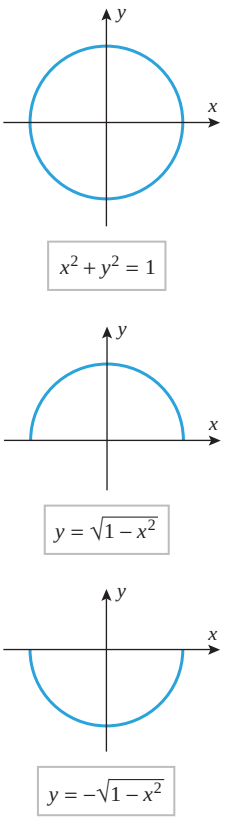
$$yx + y + 1 = x \tag{1}$$

is not of the form $y = f(x)$, but it still defines $y$ as a function of $x$ since it can be rewritten as

$$y = \frac{x - 1}{x + 1}$$

Thus, we say that (1) defines $y$ ***implicitly*** as a function of $x$, the function being

$$f(x) = \frac{x - 1}{x + 1}$$



▲ **Figure 3.1.1**

An equation in $x$ and $y$ can implicitly define more than one function of $x$. This can occur when the graph of the equation fails the vertical line test, so it is not the graph of a function of $x$. For example, if we solve the equation of the circle

$$x^2 + y^2 = 1 \tag{2}$$

for $y$ in terms of $x$, we obtain $y = \pm\sqrt{1 - x^2}$, so we have found two functions that are defined implicitly by (2), namely,

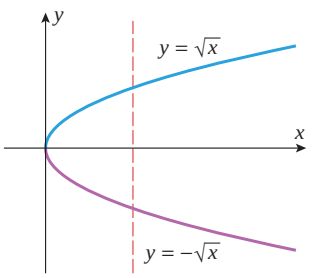
$$f_1(x) = \sqrt{1 - x^2} \quad \text{and} \quad f_2(x) = -\sqrt{1 - x^2} \tag{3}$$

The graphs of these functions are the upper and lower semicircles of the circle $x^2 + y^2 = 1$ (Figure 3.1.1). This leads us to the following definition.

**3.1.1 DEFINITION** We will say that a given equation in $x$ and $y$ defines the function $f$ ***implicitly*** if the graph of $y = f(x)$ coincides with a portion of the graph of the equation.

▶ **Example 1** The graph of $x = y^2$ is not the graph of a function of $x$, since it does not pass the vertical line test (Figure 3.1.2). However, if we solve this equation for $y$ in terms of $x$, we obtain the equations $y = \sqrt{x}$ and $y = -\sqrt{x}$, whose graphs pass the vertical line test and are portions of the graph of $x = y^2$ (Figure 3.1.2). Thus, the equation $x = y^2$ implicitly defines the functions

$$f_1(x) = \sqrt{x} \quad \text{and} \quad f_2(x) = -\sqrt{x} \quad \blacktriangleleft$$



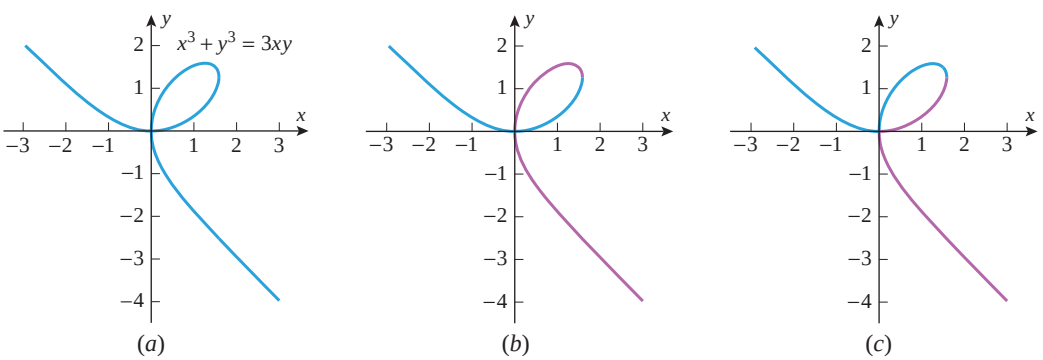
▲ **Figure 3.1.2** The graph of $x = y^2$ does not pass the vertical line test, but the graphs of $y = \sqrt{x}$ and $y = -\sqrt{x}$ do.

Although it was a trivial matter in the last example to solve the equation $x = y^2$ for $y$ in terms of $x$, it is difficult or impossible to do this for some equations. For example, the equation

$$x^3 + y^3 = 3xy \tag{4}$$

can be solved for $y$ in terms of $x$, but the resulting formulas are too complicated to be practical. Other equations, such as $\sin(xy) = y$, cannot be solved for $y$ by any elementary method. Thus, even though an equation may define one or more functions of $x$, it may not be possible or practical to find explicit formulas for those functions.

Fortunately, CAS programs, such as *Mathematica* and *Maple*, have "implicit plotting" capabilities that can graph equations such as (4). The graph of this equation, which is called the ***Folium of Descartes***, is shown in Figure 3.1.3*a*. Parts (*b*) and (*c*) of the figure show the graphs (in blue) of two functions that are defined implicitly by (4).



▲ **Figure 3.1.3**

## IMPLICIT DIFFERENTIATION

In general, it is not necessary to solve an equation for $y$ in terms of $x$ in order to differentiate the functions defined implicitly by the equation. To illustrate this, let us consider the simple equation

$$xy = 1 \tag{5}$$

One way to find $dy/dx$ is to rewrite this equation as

$$y = \frac{1}{x} \tag{6}$$

from which it follows that

$$\frac{dy}{dx} = -\frac{1}{x^2} \tag{7}$$

Another way to obtain this derivative is to differentiate both sides of (5) *before* solving for $y$ in terms of $x$, treating $y$ as a (temporarily unspecified) differentiable function of $x$. With this approach we obtain

$$\frac{d}{dx}[xy] = \frac{d}{dx}[1]$$

$$x\frac{d}{dx}[y] + y\frac{d}{dx}[x] = 0$$

$$x\frac{dy}{dx} + y = 0$$

$$\frac{dy}{dx} = -\frac{y}{x}$$

If we now substitute (6) into the last expression, we obtain

$$\frac{dy}{dx} = -\frac{1}{x^2}$$

which agrees with Equation (7). This method of obtaining derivatives is called ***implicit differentiation***.

**▶ Example 2** Use implicit differentiation to find $dy/dx$ if $5y^2 + \sin y = x^2$.

$$\frac{d}{dx}[5y^2 + \sin y] = \frac{d}{dx}[x^2]$$

$$5\frac{d}{dx}[y^2] + \frac{d}{dx}[\sin y] = 2x$$

$$5\left(2y\frac{dy}{dx}\right) + (\cos y)\frac{dy}{dx} = 2x$$

The chain rule was used here because $y$ is a function of $x$.

$$10y\frac{dy}{dx} + (\cos y)\frac{dy}{dx} = 2x$$

**René Descartes (1596–1650)** Descartes, a French aristocrat, was the son of a government official. He graduated from the University of Poitiers with a law degree at age 20. After a brief probe into the pleasures of Paris he became a military engineer, first for the Dutch Prince of Nassau and then for the German Duke of Bavaria. It was during his service as a soldier that Descartes began to pursue mathematics seriously and develop his analytic geometry. After the wars, he returned to Paris where he stalked the city as an eccentric, wearing a sword in his belt and a plumed hat. He lived in leisure, seldom arose before 11 A.M., and dabbled in the study of human physiology, philosophy, glaciers, meteors, and rainbows. He eventually moved to Holland, where he published his *Discourse on the Method*, and finally to Sweden where he died while serving as tutor to Queen Christina. Descartes is regarded as a genius of the first magnitude. In addition to major contributions in mathematics and philosophy he is considered, along with William Harvey, to be a founder of modern physiology.

[*Image: http://en.wikipedia.org/wiki/File:Frans_Hals_-_Portret_van_Ren%C3%A9_Descartes.jpg*]

Solving for $dy/dx$ we obtain

$$\frac{dy}{dx} = \frac{2x}{10y + \cos y} \tag{8}$$

Note that this formula involves both $x$ and $y$. In order to obtain a formula for $dy/dx$ that involves $x$ alone, we would have to solve the original equation for $y$ in terms of $x$ and then substitute in (8). However, it is impossible to do this, so we are forced to leave the formula for $dy/dx$ in terms of $x$ and $y$. ◀

**▶ Example 3** Use implicit differentiation to find $d^2y/dx^2$ if $4x^2 - 2y^2 = 9$.

***Solution.*** Differentiating both sides of $4x^2 - 2y^2 = 9$ with respect to $x$ yields

$$8x - 4y\frac{dy}{dx} = 0$$

from which we obtain

$$\frac{dy}{dx} = \frac{2x}{y} \tag{9}$$

Differentiating both sides of (9) yields

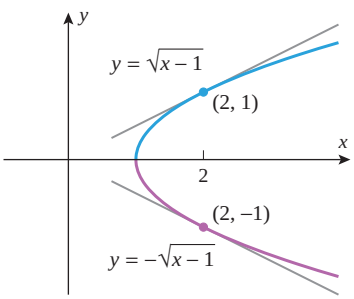
$$\frac{d^2y}{dx^2} = \frac{(y)(2) - (2x)(dy/dx)}{y^2} \tag{10}$$

Substituting (9) into (10) and simplifying using the original equation, we obtain

$$\frac{d^2y}{dx^2} = \frac{2y - 2x(2x/y)}{y^2} = \frac{2y^2 - 4x^2}{y^3} = -\frac{9}{y^3}$$ ◀

In Examples 2 and 3, the resulting formulas for $dy/dx$ involved both $x$ and $y$. Although it is usually more desirable to have the formula for $dy/dx$ expressed in terms of $x$ alone, having the formula in terms of $x$ and $y$ is not an impediment to finding slopes and equations of tangent lines provided the $x$- and $y$-coordinates of the point of tangency are known. This is illustrated in the following example.

**▶ Example 4** Find the slopes of the tangent lines to the curve $y^2 - x + 1 = 0$ at the points $(2, -1)$ and $(2, 1)$.



▲ Figure 3.1.4

***Solution.*** We could proceed by solving the equation for $y$ in terms of $x$, and then evaluating the derivative of $y = \sqrt{x-1}$ at $(2, 1)$ and the derivative of $y = -\sqrt{x-1}$ at $(2, -1)$ (Figure 3.1.4). However, implicit differentiation is more efficient since it can be used for the slopes of *both* tangent lines. Differentiating implicitly yields

$$\frac{d}{dx}[y^2 - x + 1] = \frac{d}{dx}[0]$$

$$\frac{d}{dx}[y^2] - \frac{d}{dx}[x] + \frac{d}{dx}[1] = \frac{d}{dx}[0]$$

$$2y\frac{dy}{dx} - 1 = 0$$

$$\frac{dy}{dx} = \frac{1}{2y}$$

At $(2, -1)$ we have $y = -1$, and at $(2, 1)$ we have $y = 1$, so the slopes of the tangent lines to the curve at those points are

$$\left.\frac{dy}{dx}\right|_{\substack{x=2\\y=-1}} = -\frac{1}{2} \quad \text{and} \quad \left.\frac{dy}{dx}\right|_{\substack{x=2\\y=1}} = \frac{1}{2}$$ ◀

## ▶ Example 5

(a) Use implicit differentiation to find $dy/dx$ for the Folium of Descartes $x^3 + y^3 = 3xy$.

(b) Find an equation for the tangent line to the Folium of Descartes at the point $\left(\frac{3}{2}, \frac{3}{2}\right)$.

(c) At what point(s) in the first quadrant is the tangent line to the Folium of Descartes horizontal?

***Solution (a).*** Differentiating implicitly yields

$$\frac{d}{dx}[x^3 + y^3] = \frac{d}{dx}[3xy]$$

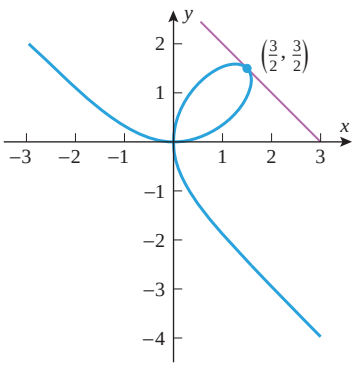
$$3x^2 + 3y^2\frac{dy}{dx} = 3x\frac{dy}{dx} + 3y$$

$$x^2 + y^2\frac{dy}{dx} = x\frac{dy}{dx} + y$$

$$(y^2 - x)\frac{dy}{dx} = y - x^2$$

$$\frac{dy}{dx} = \frac{y - x^2}{y^2 - x} \tag{11}$$

Formula (11) cannot be evaluated at $(0, 0)$ and hence provides no information about the nature of the Folium of Descartes at the origin. Based on the graphs in Figure 3.1.3, what can you say about the differentiability of the implicitly defined functions graphed in blue in parts (*b*) and (*c*) of the figure?



▲ Figure 3.1.5

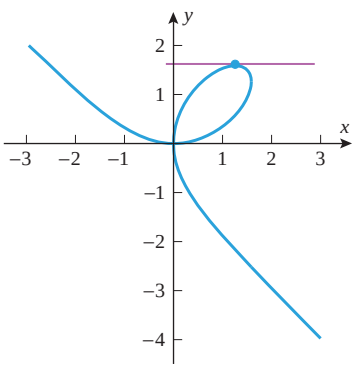
***Solution (b).*** At the point $\left(\frac{3}{2}, \frac{3}{2}\right)$, we have $x = \frac{3}{2}$ and $y = \frac{3}{2}$, so from (11) the slope $m_{\tan}$ of the tangent line at this point is

$$m_{\tan} = \left.\frac{dy}{dx}\right|_{\substack{x=3/2\\y=3/2}} = \frac{(3/2) - (3/2)^2}{(3/2)^2 - (3/2)} = -1$$

Thus, the equation of the tangent line at the point $\left(\frac{3}{2}, \frac{3}{2}\right)$ is

$$y - \tfrac{3}{2} = -1\left(x - \tfrac{3}{2}\right) \quad \text{or} \quad x + y = 3$$

which is consistent with Figure 3.1.5.



▲ Figure 3.1.6

***Solution (c).*** The tangent line is horizontal at the points where $dy/dx = 0$, and from (11) this occurs only where $y - x^2 = 0$ or

$$y = x^2 \tag{12}$$

Substituting this expression for $y$ in the equation $x^3 + y^3 = 3xy$ for the curve yields

$$x^3 + (x^2)^3 = 3x^3$$

$$x^6 - 2x^3 = 0$$

$$x^3(x^3 - 2) = 0$$

whose solutions are $x = 0$ and $x = 2^{1/3}$. From (12), the solutions $x = 0$ and $x = 2^{1/3}$ yield the points $(0, 0)$ and $(2^{1/3}, 2^{2/3})$, respectively. Of these two, only $(2^{1/3}, 2^{2/3})$ is in the first quadrant. Substituting $x = 2^{1/3}$, $y = 2^{2/3}$ into (11) yields

$$\left.\frac{dy}{dx}\right|_{\substack{x=2^{1/3}\\y=2^{2/3}}} = \frac{0}{2^{4/3} - 2^{2/3}} = 0$$

We conclude that $(2^{1/3}, 2^{2/3}) \approx (1.26, 1.59)$ is the only point on the Folium of Descartes in the first quadrant at which the tangent line is horizontal (Figure 3.1.6). ◀

### DIFFERENTIABILITY OF FUNCTIONS DEFINED IMPLICITLY

When differentiating implicitly, it is assumed that $y$ represents a differentiable function of $x$. If this is not so, then the resulting calculations may be nonsense. For example, if we differentiate the equation

$$x^2 + y^2 + 1 = 0 \tag{13}$$

we obtain

$$2x + 2y\frac{dy}{dx} = 0 \quad \text{or} \quad \frac{dy}{dx} = -\frac{x}{y}$$

However, this derivative is meaningless because there are no real values of $x$ and $y$ that satisfy (13) (why?); and hence (13) does not define any real functions implicitly.

The nonsensical conclusion of these computations conveys the importance of knowing whether an equation in $x$ and $y$ that is to be differentiated implicitly actually defines some differentiable function of $x$ implicitly. Unfortunately, this can be a difficult problem, so we will leave the discussion of such matters for more advanced courses in analysis.

## ✔ QUICK CHECK EXERCISES 3.1 (See page 192 for answers.)

1. The equation $xy + 2y = 1$ defines implicitly the function $y =$ _____.
2. Use implicit differentiation to find $dy/dx$ for $x^2 - y^3 = xy$.
3. The slope of the tangent line to the graph of $x + y + xy = 3$ at $(1, 1)$ is _____.
4. Use implicit differentiation to find $d^2y/dx^2$ for $\sin y = x$.

## EXERCISE SET 3.1 C CAS

**1–2**
(a) Find $dy/dx$ by differentiating implicitly.
(b) Solve the equation for $y$ as a function of $x$, and find $dy/dx$ from that equation.
(c) Confirm that the two results are consistent by expressing the derivative in part (a) as a function of $x$ alone. ■

**1.** $x + xy - 2x^3 = 2$ **2.** $\sqrt{y} - \sin x = 2$

**3–12** Find $dy/dx$ by implicit differentiation. ■

**3.** $x^2 + y^2 = 100$ **4.** $x^3 + y^3 = 3xy^2$

**5.** $x^2y + 3xy^3 - x = 3$ **6.** $x^3y^2 - 5x^2y + x = 1$

**7.** $\dfrac{1}{\sqrt{x}} + \dfrac{1}{\sqrt{y}} = 1$ **8.** $x^2 = \dfrac{x + y}{x - y}$

**9.** $\sin(x^2y^2) = x$ **10.** $\cos(xy^2) = y$

**11.** $\tan^3(xy^2 + y) = x$ **12.** $\dfrac{xy^3}{1 + \sec y} = 1 + y^4$

**13–18** Find $d^2y/dx^2$ by implicit differentiation. ■

**13.** $2x^2 - 3y^2 = 4$ **14.** $x^3 + y^3 = 1$

**15.** $x^3y^3 - 4 = 0$ **16.** $xy + y^2 = 2$

**17.** $y + \sin y = x$ **18.** $x \cos y = y$

**19–20** Find the slope of the tangent line to the curve at the given points in two ways: first by solving for $y$ in terms of $x$ and differentiating and then by implicit differentiation. ■

**19.** $x^2 + y^2 = 1$; $(1/2, \sqrt{3}/2), (1/2, -\sqrt{3}/2)$

**20.** $y^2 - x + 1 = 0$; $(10, 3), (10, -3)$

**21–24 True–False** Determine whether the statement is true or false. Explain your answer. ■

**21.** If an equation in $x$ and $y$ defines a function $y = f(x)$ implicitly, then the graph of the equation and the graph of $f$ are identical.

**22.** The function

$$f(x) = \begin{cases} \sqrt{1 - x^2}, & 0 < x \le 1 \\ -\sqrt{1 - x^2}, & -1 \le x \le 0 \end{cases}$$

is defined implicitly by the equation $x^2 + y^2 = 1$.

**23.** The function $|x|$ is not defined implicitly by the equation $(x + y)(x - y) = 0$.

**24.** If $y$ is defined implicitly as a function of $x$ by the equation $x^2 + y^2 = 1$, then $dy/dx = -x/y$.

**25–28** Use implicit differentiation to find the slope of the tangent line to the curve at the specified point, and check that your answer is consistent with the accompanying graph on the next page. ■

**25.** $x^4 + y^4 = 16$; $(1, \sqrt[4]{15})$ [***Lamé's special quartic***]

**26.** $y^3 + yx^2 + x^2 - 3y^2 = 0$; $(0, 3)$ [***trisectrix***]

**27.** $2(x^2 + y^2)^2 = 25(x^2 - y^2)$; $(3, 1)$ [***lemniscate***]

**28.** $x^{2/3} + y^{2/3} = 4$; $(-1, 3\sqrt{3})$ [***four-cusped hypocycloid***]

**29–32** Use implicit differentiation to find the specified derivative. ■

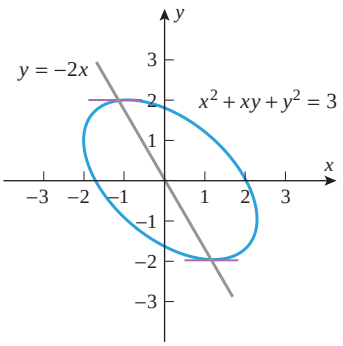
**29.** $a^4 - t^4 = 6a^2t$; $da/dt$ **30.** $\sqrt{u} + \sqrt{v} = 5$; $du/dv$

**31.** $a^2\omega^2 + b^2\lambda^2 = 1$ ($a, b$ constants); $d\omega/d\lambda$

**32.** $y = \sin x$; $dx/dy$

**FOCUS ON CONCEPTS**

**33.** In the accompanying figure, it appears that the ellipse $x^2 + xy + y^2 = 3$ has horizontal tangent lines at the points of intersection of the ellipse and the line $y = -2x$. Use implicit differentiation to explain why this is the case.



◀ Figure Ex-33

**34.** (a) A student claims that the ellipse $x^2 - xy + y^2 = 1$ has a horizontal tangent line at the point $(1, 1)$. Without doing any computations, explain why the student's claim must be incorrect.

(b) Find all points on the ellipse $x^2 - xy + y^2 = 1$ at which the tangent line is horizontal.

C **35.** (a) Use the implicit plotting capability of a CAS to graph the equation $y^4 + y^2 = x(x - 1)$.

(b) Use implicit differentiation to help explain why the graph in part (a) has no horizontal tangent lines.

(c) Solve the equation $y^4 + y^2 = x(x - 1)$ for $x$ in terms of $y$ and explain why the graph in part (a) consists of two parabolas.

**36.** Use implicit differentiation to find all points on the graph of $y^4 + y^2 = x(x - 1)$ at which the tangent line is vertical.

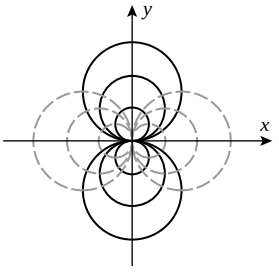
**37.** Find the values of $a$ and $b$ for the curve $x^2y + ay^2 = b$ if the point $(1, 1)$ is on its graph and the tangent line at $(1, 1)$ has the equation $4x + 3y = 7$.

**38.** At what point(s) is the tangent line to the curve $y^3 = 2x^2$ perpendicular to the line $x + 2y - 2 = 0$?

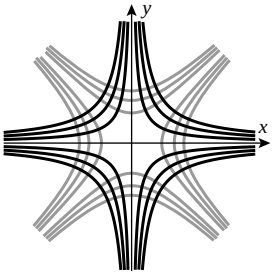
**39–40** Two curves are said to be ***orthogonal*** if their tangent lines are perpendicular at each point of intersection, and two families of curves are said to be ***orthogonal trajectories*** of one another if each member of one family is orthogonal to each member of the other family. This terminology is used in these exercises. ■

**39.** The accompanying figure shows some typical members of the families of circles $x^2 + (y - c)^2 = c^2$ (black curves) and $(x - k)^2 + y^2 = k^2$ (gray curves). Show that these families are orthogonal trajectories of one another. [*Hint:* For the tangent lines to be perpendicular at a point of intersection, the slopes of those tangent lines must be negative reciprocals of one another.]

**40.** The accompanying figure shows some typical members of the families of hyperbolas $xy = c$ (black curves) and $x^2 - y^2 = k$ (gray curves), where $c \neq 0$ and $k \neq 0$. Use the hint in Exercise 39 to show that these families are orthogonal trajectories of one another.



▲ Figure Ex-39



▲ Figure Ex-40

C **41.** (a) Use the implicit plotting capability of a CAS to graph the curve $C$ whose equation is $x^3 - 2xy + y^3 = 0$.

(b) Use the graph in part (a) to estimate the $x$-coordinates of a point in the first quadrant that is on $C$ and at which the tangent line to $C$ is parallel to the $x$-axis.

(c) Find the exact value of the $x$-coordinate in part (b).

C **42.** (a) Use the implicit plotting capability of a CAS to graph the curve $C$ whose equation is $x^3 - 2xy + y^3 = 0$.

(b) Use the graph to guess the coordinates of a point in the first quadrant that is on $C$ and at which the tangent line to $C$ is parallel to the line $y = -x$.

(c) Use implicit differentiation to verify your conjecture in part (b).

**43.** Find $dy/dx$ if

$$2y^3t + t^3y = 1 \quad \text{and} \quad \frac{dt}{dx} = \frac{1}{\cos t}$$

**44.** Find equations for two lines through the origin that are tangent to the ellipse $2x^2 - 4x + y^2 + 1 = 0$.

**45.** **Writing** Write a paragraph that compares the concept of an *explicit* definition of a function with that of an *implicit* definition of a function.

**46.** **Writing** A student asks: "Suppose implicit differentiation yields an undefined expression at a point. Does this mean that $dy/dx$ is undefined at that point?" Using the equation $x^2 - 2xy + y^2 = 0$ as a basis for your discussion, write a paragraph that answers the student's question.

### ✔ QUICK CHECK ANSWERS 3.1

**1.** $\dfrac{1}{x+2}$ **2.** $\dfrac{dy}{dx} = \dfrac{2x - y}{x + 3y^2}$ **3.** $-1$ **4.** $\dfrac{d^2y}{dx^2} = \sec^2 y \tan y$

## 3.2 DERIVATIVES OF LOGARITHMIC FUNCTIONS

*In this section we will obtain derivative formulas for logarithmic functions, and we will explain why the natural logarithm function is preferred over logarithms with other bases in calculus.*

### DERIVATIVES OF LOGARITHMIC FUNCTIONS

We will establish that $f(x) = \ln x$ is differentiable for $x > 0$ by applying the derivative definition to $f(x)$. To evaluate the resulting limit, we will need the fact that $\ln x$ is continuous for $x > 0$ (Theorem 1.6.3), and we will need the limit

$$\lim_{v \to 0} (1 + v)^{1/v} = e \tag{1}$$

This limit can be obtained from limits (7) and (8) of Section 1.3 by making the substitution $v = 1/x$ and using the fact that $v \to 0^+$ as $x \to +\infty$ and $v \to 0^-$ as $x \to -\infty$. This produces two equal one-sided limits that together imply (1) (see Exercise 64 of Section 1.3).

$$\begin{aligned}
\frac{d}{dx}[\ln x] &= \lim_{h \to 0} \frac{\ln(x + h) - \ln x}{h} \\
&= \lim_{h \to 0} \frac{1}{h} \ln\left(\frac{x + h}{x}\right) && \text{The quotient property of logarithms in Theorem 0.5.2} \\
&= \lim_{h \to 0} \frac{1}{h} \ln\left(1 + \frac{h}{x}\right) \\
&= \lim_{v \to 0} \frac{1}{vx} \ln(1 + v) && \text{Let } v = h/x \text{ and note that } v \to 0 \text{ if and only if } h \to 0. \\
&= \frac{1}{x} \lim_{v \to 0} \frac{1}{v} \ln(1 + v) && x \text{ is fixed in this limit computation, so } 1/x \text{ can be moved through the limit sign.} \\
&= \frac{1}{x} \lim_{v \to 0} \ln(1 + v)^{1/v} && \text{The power property of logarithms in Theorem 0.5.2} \\
&= \frac{1}{x} \ln\left[\lim_{v \to 0} (1 + v)^{1/v}\right] && \ln x \text{ is continuous on } (0, +\infty) \text{ so we can move the limit through the function symbol.} \\
&= \frac{1}{x} \ln e \\
&= \frac{1}{x} && \text{Since } \ln e = 1
\end{aligned}$$

Thus,

$$\frac{d}{dx}[\ln x] = \frac{1}{x}, \quad x > 0 \tag{2}$$

A derivative formula for the general logarithmic function $\log_b x$ can be obtained from (2) by using Formula (6) of Section 0.5 to write

$$\frac{d}{dx}[\log_b x] = \frac{d}{dx}\left[\frac{\ln x}{\ln b}\right] = \frac{1}{\ln b}\frac{d}{dx}[\ln x]$$

It follows from this that

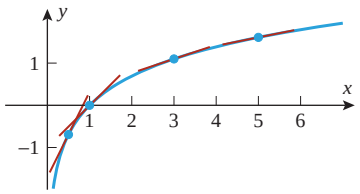
$$\frac{d}{dx}[\log_b x] = \frac{1}{x \ln b}, \quad x > 0 \tag{3}$$

Note that, among all possible bases, the base $b = e$ produces the simplest formula for the derivative of $\log_b x$. This is one of the reasons why the natural logarithm function is preferred over other logarithms in calculus.

### ▶ Example 1

(a) Figure 3.2.1 shows the graph of $y = \ln x$ and its tangent lines at the points $x = \frac{1}{2}$, 1, 3, and 5. Find the slopes of those tangent lines.

(b) Does the graph of $y = \ln x$ have any horizontal tangent lines? Use the derivative of $\ln x$ to justify your answer.



$y = \ln x$ with tangent lines

▲ Figure 3.2.1

***Solution (a).*** From (2), the slopes of the tangent lines at the points $x = \frac{1}{2}$, 1, 3, and 5 are $1/x = 2$, 1, $\frac{1}{3}$, and $\frac{1}{5}$, respectively, which is consistent with Figure 3.2.1.

***Solution (b).*** It does not appear from the graph of $y = \ln x$ that there are any horizontal tangent lines. This is confirmed by the fact that $dy/dx = 1/x$ is not equal to zero for any real value of $x$. ◀

If $u$ is a differentiable function of $x$, and if $u(x) > 0$, then applying the chain rule to (2) and (3) produces the following generalized derivative formulas:

$$\frac{d}{dx}[\ln u] = \frac{1}{u} \cdot \frac{du}{dx} \quad \text{and} \quad \frac{d}{dx}[\log_b u] = \frac{1}{u \ln b} \cdot \frac{du}{dx} \tag{4–5}$$

### ▶ Example 2

Find $\dfrac{d}{dx}[\ln(x^2 + 1)]$.

***Solution.*** Using (4) with $u = x^2 + 1$ we obtain

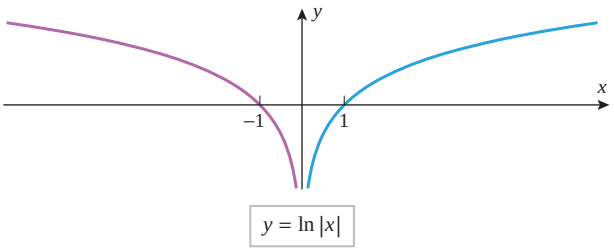
$$\frac{d}{dx}[\ln(x^2 + 1)] = \frac{1}{x^2 + 1} \cdot \frac{d}{dx}[x^2 + 1] = \frac{1}{x^2 + 1} \cdot 2x = \frac{2x}{x^2 + 1}$$ ◀

When possible, the properties of logarithms in Theorem 0.5.2 should be used to convert products, quotients, and exponents into sums, differences, and constant multiples *before* differentiating a function involving logarithms.

### ▶ Example 3

$$\begin{aligned}\frac{d}{dx}\left[\ln\left(\frac{x^2 \sin x}{\sqrt{1+x}}\right)\right] &= \frac{d}{dx}\left[2\ln x + \ln(\sin x) - \frac{1}{2}\ln(1+x)\right] \\ &= \frac{2}{x} + \frac{\cos x}{\sin x} - \frac{1}{2(1+x)} \\ &= \frac{2}{x} + \cot x - \frac{1}{2+2x}\end{aligned}$$ ◀

Figure 3.2.2 shows the graph of $f(x) = \ln|x|$. This function is important because it "extends" the domain of the natural logarithm function in the sense that the values of $\ln|x|$ and $\ln x$ are the same for $x > 0$, but $\ln|x|$ is defined for all nonzero values of $x$, and $\ln x$ is only defined for positive values of $x$.



▶ **Figure 3.2.2**

The derivative of $\ln|x|$ for $x \neq 0$ can be obtained by considering the cases $x > 0$ and $x < 0$ separately:

**Case $x > 0$.** In this case $|x| = x$, so

$$\frac{d}{dx}[\ln|x|] = \frac{d}{dx}[\ln x] = \frac{1}{x}$$

**Case $x < 0$.** In this case $|x| = -x$, so it follows from (4) that

$$\frac{d}{dx}[\ln|x|] = \frac{d}{dx}[\ln(-x)] = \frac{1}{(-x)} \cdot \frac{d}{dx}[-x] = \frac{1}{x}$$

Since the same formula results in both cases, we have shown that

$$\frac{d}{dx}[\ln|x|] = \frac{1}{x} \quad \text{if } x \neq 0 \tag{6}$$

▶ **Example 4** From (6) and the chain rule,

$$\frac{d}{dx}[\ln|\sin x|] = \frac{1}{\sin x} \cdot \frac{d}{dx}[\sin x] = \frac{\cos x}{\sin x} = \cot x \quad \blacktriangleleft$$

## LOGARITHMIC DIFFERENTIATION

We now consider a technique called ***logarithmic differentiation*** that is useful for differentiating functions that are composed of products, quotients, and powers.

▶ **Example 5** The derivative of

$$y = \frac{x^2\sqrt[3]{7x-14}}{(1+x^2)^4} \tag{7}$$

is messy to calculate directly. However, if we first take the natural logarithm of both sides and then use its properties, we can write

$$\ln y = 2\ln x + \tfrac{1}{3}\ln(7x-14) - 4\ln(1+x^2)$$

Differentiating both sides with respect to $x$ yields

$$\frac{1}{y}\frac{dy}{dx} = \frac{2}{x} + \frac{7/3}{7x-14} - \frac{8x}{1+x^2}$$

Thus, on solving for $dy/dx$ and using (7) we obtain

$$\frac{dy}{dx} = \frac{x^2\sqrt[3]{7x-14}}{(1+x^2)^4}\left[\frac{2}{x} + \frac{1}{3x-6} - \frac{8x}{1+x^2}\right] \blacktriangleleft$$

**REMARK** Since $\ln y$ is only defined for $y > 0$, the computations in Example 5 are only valid for $x > 2$ (verify). However, because the derivative of $\ln y$ is the same as the derivative of $\ln|y|$, and because $\ln|y|$ is defined for $y < 0$ as well as $y > 0$, it follows that the formula obtained for $dy/dx$ is valid for $x < 2$ as well as $x > 2$. In general, whenever a derivative $dy/dx$ is obtained by logarithmic differentiation, the resulting derivative formula will be valid for all values of $x$ for which $y \neq 0$. It may be valid at those points as well, but it is not guaranteed.

## DERIVATIVES OF REAL POWERS OF *x*

We know from Theorem 2.3.2 and Exercise 82 in Section 2.3, that the differentiation formula

$$\frac{d}{dx}[x^r] = rx^{r-1} \tag{8}$$

holds for constant integer values of $r$. We will now use logarithmic differentiation to show that this formula holds if $r$ is *any* real number (rational or irrational). In our computations we will assume that $x^r$ is a differentiable function and that the familiar laws of exponents hold for real exponents.

In the next section we will discuss differentiating functions that have exponents which are not constant.

Let $y = x^r$, where $r$ is a real number. The derivative $dy/dx$ can be obtained by logarithmic differentiation as follows:

$$\ln|y| = \ln|x^r| = r\ln|x|$$

$$\frac{d}{dx}[\ln|y|] = \frac{d}{dx}[r\ln|x|]$$

$$\frac{1}{y}\frac{dy}{dx} = \frac{r}{x}$$

$$\frac{dy}{dx} = \frac{r}{x}y = \frac{r}{x}x^r = rx^{r-1}$$

## ✔ QUICK CHECK EXERCISES 3.2 (See page 196 for answers.)

1. The equation of the tangent line to the graph of $y = \ln x$ at $x = e^2$ is _____.
2. Find $dy/dx$.
   (a) $y = \ln 3x$ (b) $y = \ln\sqrt{x}$
   (c) $y = \log(1/|x|)$
3. Use logarithmic differentiation to find the derivative of
$$f(x) = \frac{\sqrt{x+1}}{\sqrt[3]{x-1}}$$
4. $\lim_{h\to 0}\dfrac{\ln(1+h)}{h} =$ _____

## EXERCISE SET 3.2

**1–26** Find $dy/dx$. ■

1. $y = \ln 5x$
2. $y = \ln\dfrac{x}{3}$
3. $y = \ln|1+x|$
4. $y = \ln(2+\sqrt{x})$
5. $y = \ln|x^2-1|$
6. $y = \ln|x^3 - 7x^2 - 3|$
7. $y = \ln\left(\dfrac{x}{1+x^2}\right)$
8. $y = \ln\left|\dfrac{1+x}{1-x}\right|$
9. $y = \ln x^2$
10. $y = (\ln x)^3$
11. $y = \sqrt{\ln x}$
12. $y = \ln\sqrt{x}$
13. $y = x\ln x$
14. $y = x^3\ln x$
15. $y = x^2\log_2(3-2x)$
16. $y = x[\log_2(x^2-2x)]^3$
17. $y = \dfrac{x^2}{1+\log x}$
18. $y = \dfrac{\log x}{1+\log x}$
19. $y = \ln(\ln x)$
20. $y = \ln(\ln(\ln x))$
21. $y = \ln(\tan x)$
22. $y = \ln(\cos x)$
23. $y = \cos(\ln x)$
24. $y = \sin^2(\ln x)$
25. $y = \log(\sin^2 x)$
26. $y = \log(1-\sin^2 x)$

**27–30** Use the method of Example 3 to help perform the indicated differentiation. ■

**27.** $\dfrac{d}{dx}[\ln((x-1)^3(x^2+1)^4)]$

**28.** $\dfrac{d}{dx}[\ln((\cos^2 x)\sqrt{1+x^4})]$

**29.** $\dfrac{d}{dx}\left[\ln\dfrac{\cos x}{\sqrt{4-3x^2}}\right]$ **30.** $\dfrac{d}{dx}\left[\ln\sqrt{\dfrac{x-1}{x+1}}\right]$

**31–34 True–False** Determine whether the statement is true or false. Explain your answer. ■

**31.** The slope of the tangent line to the graph of $y=\ln x$ at $x=a$ approaches infinity as $a\to 0^+$.

**32.** If $\lim_{x\to+\infty} f'(x)=0$, then the graph of $y=f(x)$ has a horizontal asymptote.

**33.** The derivative of $\ln|x|$ is an odd function.

**34.** We have

$$\frac{d}{dx}((\ln x)^2)=\frac{d}{dx}(2(\ln x))=\frac{2}{x}$$

**35–38** Find $dy/dx$ using logarithmic differentiation. ■

**35.** $y=x\sqrt[3]{1+x^2}$ **36.** $y=\sqrt[5]{\dfrac{x-1}{x+1}}$

**37.** $y=\dfrac{(x^2-8)^{1/3}\sqrt{x^3+1}}{x^6-7x+5}$ **38.** $y=\dfrac{\sin x\cos x\tan^3 x}{\sqrt{x}}$

**39.** Find

(a) $\dfrac{d}{dx}[\log_x e]$ (b) $\dfrac{d}{dx}[\log_x 2]$.

**40.** Find

(a) $\dfrac{d}{dx}[\log_{(1/x)} e]$ (b) $\dfrac{d}{dx}[\log_{(\ln x)} e]$.

**41–44** Find the equation of the tangent line to the graph of $y=f(x)$ at $x=x_0$. ■

**41.** $f(x)=\ln x;\ x_0=e^{-1}$ **42.** $f(x)=\log x;\ x_0=10$

**43.** $f(x)=\ln(-x);\ x_0=-e$ **44.** $f(x)=\ln|x|;\ x_0=-2$

**FOCUS ON CONCEPTS**

**45.** (a) Find the equation of a line through the origin that is tangent to the graph of $y=\ln x$.

(b) Explain why the $y$-intercept of a tangent line to the curve $y=\ln x$ must be 1 unit less than the $y$-coordinate of the point of tangency.

**46.** Use logarithmic differentiation to verify the product and quotient rules. Explain what properties of $\ln x$ are important for this verification.

**47.** Find a formula for the area $A(w)$ of the triangle bounded by the tangent line to the graph of $y=\ln x$ at $P(w,\ln w)$, the horizontal line through $P$, and the $y$-axis.

**48.** Find a formula for the area $A(w)$ of the triangle bounded by the tangent line to the graph of $y=\ln x^2$ at $P(w,\ln w^2)$, the horizontal line through $P$, and the $y$-axis.

**49.** Verify that $y=\ln(x+e)$ satisfies $dy/dx=e^{-y}$, with $y=1$ when $x=0$.

**50.** Verify that $y=-\ln(e^2-x)$ satisfies $dy/dx=e^y$, with $y=-2$ when $x=0$.

**51.** Find a function $f$ such that $y=f(x)$ satisfies $dy/dx=e^{-y}$, with $y=0$ when $x=0$.

**52.** Find a function $f$ such that $y=f(x)$ satisfies $dy/dx=e^y$, with $y=-\ln 2$ when $x=0$.

**53–55** Find the limit by interpreting the expression as an appropriate derivative. ■

**53.** (a) $\lim\limits_{x\to 0}\dfrac{\ln(1+3x)}{x}$ (b) $\lim\limits_{x\to 0}\dfrac{\ln(1-5x)}{x}$

**54.** (a) $\lim\limits_{\Delta x\to 0}\dfrac{\ln(e^2+\Delta x)-2}{\Delta x}$ (b) $\lim\limits_{w\to 1}\dfrac{\ln w}{w-1}$

**55.** (a) $\lim\limits_{x\to 0}\dfrac{\ln(\cos x)}{x}$ (b) $\lim\limits_{h\to 0}\dfrac{(1+h)^{\sqrt{2}}-1}{h}$

**56.** Modify the derivation of Equation (2) to give another proof of Equation (3).

**57.** Let $p$ denote the number of paramecia in a nutrient solution $t$ days after the start of an experiment, and assume that $p$ is defined implicitly as a function of $t$ by the equation

$$0=\ln p+0.83-\ln(2.3-0.0046p)-2.3t$$

Use implicit differentiation to show that the rate of change of $p$ with respect to $t$ satisfies the equation

$$\frac{dp}{dt}=0.0046p(500-p)$$

**58.** Let $p$ denote the population of the United States (in millions) in the year $t$, and assume that $p$ is defined implicitly as a function of $t$ by the equation

$$0=\ln p+45.817-\ln(2225-4.2381p)-0.02225t$$

Use implicit differentiation to show that the rate of change of $p$ with respect to $t$ satisfies the equation

$$\frac{dp}{dt}=10^{-5}p(2225-4.2381p)$$

**59. Writing** Review the derivation of the formula

$$\frac{d}{dx}[\ln x]=\frac{1}{x}$$

and then write a paragraph that discusses all the ingredients (theorems, limit properties, etc.) that are needed for this derivation.

**60. Writing** Write a paragraph that explains how logarithmic differentiation can replace a difficult differentiation computation with a simpler computation.

# 3.3 DERIVATIVES OF EXPONENTIAL AND INVERSE TRIGONOMETRIC FUNCTIONS

See Section 0.4 for a review of one-to-one functions and inverse functions.

*In this section we will show how the derivative of a one-to-one function can be used to obtain the derivative of its inverse function. This will provide the tools we need to obtain derivative formulas for exponential functions from the derivative formulas for logarithmic functions and to obtain derivative formulas for inverse trigonometric functions from the derivative formulas for trigonometric functions.*

Our first goal in this section is to obtain a formula relating the derivative of the inverse function $f^{-1}$ to the derivative of the function $f$.

**Example 1** Suppose that $f$ is a one-to-one differentiable function such that $f(2) = 1$ and $f'(2) = \frac{3}{4}$. Then the tangent line to $y = f(x)$ at the point $(2, 1)$ has equation

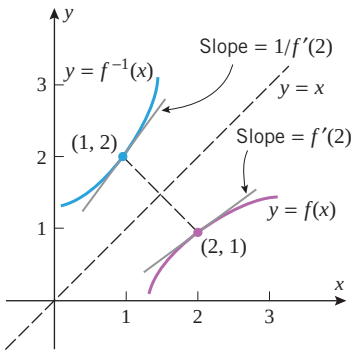
$$y - 1 = \tfrac{3}{4}(x - 2)$$

The tangent line to $y = f^{-1}(x)$ at the point $(1, 2)$ is the reflection about the line $y = x$ of the tangent line to $y = f(x)$ at the point $(2, 1)$ (Figure 3.3.1), and its equation can be obtained by interchanging $x$ and $y$:

$$x - 1 = \tfrac{3}{4}(y - 2) \quad \text{or} \quad y - 2 = \tfrac{4}{3}(x - 1)$$

Notice that the slope of the tangent line to $y = f^{-1}(x)$ at $x = 1$ is the reciprocal of the slope of the tangent line to $y = f(x)$ at $x = 2$. That is,

$$(f^{-1})'(1) = \frac{1}{f'(2)} = \frac{4}{3} \quad \blacktriangleleft \tag{1}$$



▲ **Figure 3.3.1**

Since $2 = f^{-1}(1)$ for the function $f$ in Example 1, it follows that $f'(2) = f'(f^{-1}(1))$. Thus, Formula (1) can also be expressed as

$$(f^{-1})'(1) = \frac{1}{f'(f^{-1}(1))}$$

In general, if $f$ is a differentiable and one-to-one function, then

$$(f^{-1})'(x) = \frac{1}{f'(f^{-1}(x))} \tag{2}$$

provided $f'(f^{-1}(x)) \neq 0$.

Formula (2) can be confirmed using implicit differentiation. The equation $y = f^{-1}(x)$ is equivalent to $x = f(y)$. Differentiating with respect to $x$ we obtain

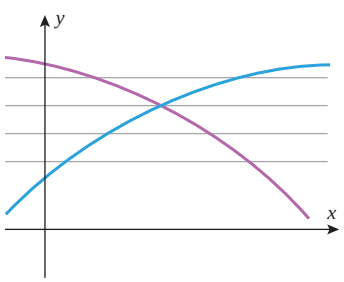
$$1 = \frac{d}{dx}[x] = \frac{d}{dx}[f(y)] = f'(y) \cdot \frac{dy}{dx}$$

so that

$$\frac{dy}{dx} = \frac{1}{f'(y)} = \frac{1}{f'(f^{-1}(x))}$$

Also from $x = f(y)$ we have $dx/dy = f'(y)$, which gives the following alternative version of Formula (2):

$$\frac{dy}{dx} = \frac{1}{dx/dy} \tag{3}$$



▲ **Figure 3.3.2** The graph of an increasing function (blue) or a decreasing function (purple) is cut at most once by any horizontal line.

## INCREASING OR DECREASING FUNCTIONS ARE ONE-TO-ONE

If the graph of a function $f$ is always increasing or always decreasing over the domain of $f$, then a horizontal line will cut the graph of $f$ in at most one point (Figure 3.3.2), so $f$

must have an inverse function (see Section 0.4). We will prove in the next chapter that $f$ is increasing on any interval on which $f'(x) > 0$ (since the graph has positive slope) and that $f$ is decreasing on any interval on which $f'(x) < 0$ (since the graph has negative slope). These intuitive observations, together with Formula (2), suggest the following theorem, which we state without formal proof.

**3.3.1 THEOREM** *Suppose that the domain of a function $f$ is an open interval on which $f'(x) > 0$ or on which $f'(x) < 0$. Then $f$ is one-to-one, $f^{-1}(x)$ is differentiable at all values of $x$ in the range of $f$, and the derivative of $f^{-1}(x)$ is given by Formula (2).*

▶ **Example 2** Consider the function $f(x) = x^5 + x + 1$.

(a) Show that $f$ is one-to-one on the interval $(-\infty, +\infty)$.

(b) Find a formula for the derivative of $f^{-1}$.

(c) Compute $(f^{-1})'(1)$.

In general, once it is established that $f^{-1}$ is differentiable, one has the option of calculating the derivative of $f^{-1}$ using Formula (2) or (3), or by differentiating implicitly, as in Example 2.

***Solution (a).*** Since

$$f'(x) = 5x^4 + 1 > 0$$

for all real values of $x$, it follows from Theorem 3.3.1 that $f$ is one-to-one on the interval $(-\infty, +\infty)$.

***Solution (b).*** Let $y = f^{-1}(x)$. Differentiating $x = f(y) = y^5 + y + 1$ implicitly with respect to $x$ yields

$$\frac{d}{dx}[x] = \frac{d}{dx}[y^5 + y + 1]$$

$$1 = (5y^4 + 1)\frac{dy}{dx}$$

$$\frac{dy}{dx} = \frac{1}{5y^4 + 1} \tag{4}$$

We cannot solve $x = y^5 + y + 1$ for $y$ in terms of $x$, so we leave the expression for $dy/dx$ in Equation (4) in terms of $y$.

***Solution (c).*** From Equation (4),

$$(f^{-1})'(1) = \left.\frac{dy}{dx}\right|_{x=1} = \left.\frac{1}{5y^4 + 1}\right|_{x=1}$$

Thus, we need to know the value of $y = f^{-1}(x)$ at $x = 1$, which we can obtain by solving the equation $f(y) = 1$ for $y$. This equation is $y^5 + y + 1 = 1$, which, by inspection, is satisfied by $y = 0$. Thus,

$$(f^{-1})'(1) = \left.\frac{1}{5y^4 + 1}\right|_{y=0} = 1 \quad ◀$$

## DERIVATIVES OF EXPONENTIAL FUNCTIONS

Our next objective is to show that the general exponential function $b^x$ $(b > 0, b \neq 1)$ is differentiable everywhere and to find its derivative. To do this, we will use the fact that

$b^x$ is the inverse of the function $f(x) = \log_b x$. We will assume that $b > 1$. With this assumption we have $\ln b > 0$, so

$$f'(x) = \frac{d}{dx}[\log_b x] = \frac{1}{x \ln b} > 0 \quad \text{for all } x \text{ in the interval } (0, +\infty)$$

It now follows from Theorem 3.3.1 that $f^{-1}(x) = b^x$ is differentiable for all $x$ in the range of $f(x) = \log_b x$. But we know from Table 0.5.3 that the range of $\log_b x$ is $(-\infty, +\infty)$, so we have established that $b^x$ is differentiable everywhere.

To obtain a derivative formula for $b^x$ we rewrite $y = b^x$ as

$$x = \log_b y$$

and differentiate implicitly using Formula (5) of Section 3.2 to obtain

$$1 = \frac{1}{y \ln b} \cdot \frac{dy}{dx}$$

Solving for $dy/dx$ and replacing $y$ by $b^x$ we have

$$\frac{dy}{dx} = y \ln b = b^x \ln b$$

How does the derivation of Formula (5) change if $0 < b < 1$?

Thus, we have shown that

$$\frac{d}{dx}[b^x] = b^x \ln b \tag{5}$$

In the special case where $b = e$ we have $\ln e = 1$, so that (5) becomes

$$\frac{d}{dx}[e^x] = e^x \tag{6}$$

In Section 0.5 we stated that $b = e$ is the only base for which the slope of the tangent line to the curve $y = b^x$ at any point $P$ on the curve is the $y$-coordinate at $P$ (see page 54). Verify this statement.

Moreover, if $u$ is a differentiable function of $x$, then it follows from (5) and (6) that

$$\frac{d}{dx}[b^u] = b^u \ln b \cdot \frac{du}{dx} \quad \text{and} \quad \frac{d}{dx}[e^u] = e^u \cdot \frac{du}{dx} \tag{7–8}$$

It is important to distinguish between differentiating an exponential function $b^x$ (variable exponent and constant base) and a power function $x^b$ (variable base and constant exponent). For example, compare the derivative

$$\frac{d}{dx}[x^2] = 2x$$

to the derivative of $2^x$ in Example 3.

**▶ Example 3** The following computations use Formulas (7) and (8).

$$\frac{d}{dx}[2^x] = 2^x \ln 2$$

$$\frac{d}{dx}[e^{-2x}] = e^{-2x} \cdot \frac{d}{dx}[-2x] = -2e^{-2x}$$

$$\frac{d}{dx}[e^{x^3}] = e^{x^3} \cdot \frac{d}{dx}[x^3] = 3x^2 e^{x^3}$$

$$\frac{d}{dx}[e^{\cos x}] = e^{\cos x} \cdot \frac{d}{dx}[\cos x] = -(\sin x)e^{\cos x} \quad \blacktriangleleft$$

Functions of the form $f(x) = u^v$ in which $u$ and $v$ are *nonconstant* functions of $x$ are neither exponential functions nor power functions. Functions of this form can be differentiated using logarithmic differentiation.

**▶ Example 4** Use logarithmic differentiation to find $\frac{d}{dx}[(x^2 + 1)^{\sin x}]$.

***Solution.*** Setting $y = (x^2 + 1)^{\sin x}$ we have

$$\ln y = \ln[(x^2 + 1)^{\sin x}] = (\sin x) \ln(x^2 + 1)$$

Differentiating both sides with respect to $x$ yields

$$\frac{1}{y}\frac{dy}{dx} = \frac{d}{dx}[(\sin x)\ln(x^2+1)]$$
$$= (\sin x)\frac{1}{x^2+1}(2x) + (\cos x)\ln(x^2+1)$$

Thus,

$$\frac{dy}{dx} = y\left[\frac{2x\sin x}{x^2+1} + (\cos x)\ln(x^2+1)\right]$$
$$= (x^2+1)^{\sin x}\left[\frac{2x\sin x}{x^2+1} + (\cos x)\ln(x^2+1)\right] \blacktriangleleft$$

## DERIVATIVES OF THE INVERSE TRIGONOMETRIC FUNCTIONS

To obtain formulas for the derivatives of the inverse trigonometric functions, we will need to use some of the identities given in Formulas (11) to (17) of Section 0.4. Rather than memorize those identities, we recommend that you review the "triangle technique" that we used to obtain them.

To begin, consider the function $\sin^{-1} x$. If we let $f(x) = \sin x$ $(-\pi/2 \le x \le \pi/2)$, then it follows from Formula (2) that $f^{-1}(x) = \sin^{-1} x$ will be differentiable at any point $x$ where $\cos(\sin^{-1} x) \ne 0$. This is equivalent to the condition

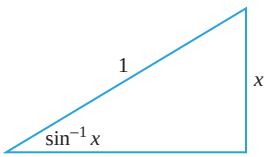
$$\sin^{-1} x \ne -\frac{\pi}{2} \quad \text{and} \quad \sin^{-1} x \ne \frac{\pi}{2}$$

so it follows that $\sin^{-1} x$ is differentiable on the interval $(-1, 1)$.

A derivative formula for $\sin^{-1} x$ on $(-1, 1)$ can be obtained by using Formula (2) or (3) or by differentiating implicitly. We will use the latter method. Rewriting the equation $y = \sin^{-1} x$ as $x = \sin y$ and differentiating implicitly with respect to $x$, we obtain

$$\frac{d}{dx}[x] = \frac{d}{dx}[\sin y]$$
$$1 = \cos y \cdot \frac{dy}{dx}$$
$$\frac{dy}{dx} = \frac{1}{\cos y} = \frac{1}{\cos(\sin^{-1} x)}$$

Observe that $\sin^{-1} x$ is only differentiable on the interval $(-1, 1)$, even though its domain is $[-1, 1]$. This is because the graph of $y = \sin x$ has horizontal tangent lines at the points $(\pi/2, 1)$ and $(-\pi/2, -1)$, so the graph of $y = \sin^{-1} x$ has vertical tangent lines at $x = \pm 1$.



$\cos(\sin^{-1} x) = \sqrt{1-x^2}$

▲ Figure 3.3.3

At this point we have succeeded in obtaining the derivative; however, this derivative formula can be simplified using the identity indicated in Figure 3.3.3. This yields

$$\frac{dy}{dx} = \frac{1}{\sqrt{1-x^2}}$$

Thus, we have shown that

$$\frac{d}{dx}[\sin^{-1} x] = \frac{1}{\sqrt{1-x^2}} \qquad (-1 < x < 1)$$

More generally, if $u$ is a differentiable function of $x$, then the chain rule produces the following generalized version of this formula:

$$\frac{d}{dx}[\sin^{-1} u] = \frac{1}{\sqrt{1-u^2}}\frac{du}{dx} \qquad (-1 < u < 1)$$

The method used to derive this formula can be used to obtain generalized derivative formulas for the remaining inverse trigonometric functions. The following is a complete list of these

formulas, each of which is valid on the natural domain of the function that multiplies $du/dx$.

$$\frac{d}{dx}[\sin^{-1} u] = \frac{1}{\sqrt{1-u^2}}\frac{du}{dx} \qquad \frac{d}{dx}[\cos^{-1} u] = -\frac{1}{\sqrt{1-u^2}}\frac{du}{dx} \tag{9–10}$$

$$\frac{d}{dx}[\tan^{-1} u] = \frac{1}{1+u^2}\frac{du}{dx} \qquad \frac{d}{dx}[\cot^{-1} u] = -\frac{1}{1+u^2}\frac{du}{dx} \tag{11–12}$$

$$\frac{d}{dx}[\sec^{-1} u] = \frac{1}{|u|\sqrt{u^2-1}}\frac{du}{dx} \qquad \frac{d}{dx}[\csc^{-1} u] = -\frac{1}{|u|\sqrt{u^2-1}}\frac{du}{dx} \tag{13–14}$$

The appearance of $|u|$ in (13) and (14) will be explained in Exercise 64.

**▶ Example 5** Find $dy/dx$ if

(a) $y = \sin^{-1}(x^3)$ (b) $y = \sec^{-1}(e^x)$

***Solution (a).*** From (9)

$$\frac{dy}{dx} = \frac{1}{\sqrt{1-(x^3)^2}}(3x^2) = \frac{3x^2}{\sqrt{1-x^6}}$$

***Solution (b).*** From (13)

$$\frac{dy}{dx} = \frac{1}{e^x\sqrt{(e^x)^2-1}}(e^x) = \frac{1}{\sqrt{e^{2x}-1}}$$ ◀

## ✔ QUICK CHECK EXERCISES 3.3 (See page 203 for answers.)

1. Suppose that a one-to-one function $f$ has tangent line $y = 5x + 3$ at the point $(1, 8)$. Evaluate $(f^{-1})'(8)$.
2. In each case, from the given derivative, determine whether the function $f$ is invertible.
   (a) $f'(x) = x^2 + 1$ (b) $f'(x) = x^2 - 1$
   (c) $f'(x) = \sin x$ (d) $f'(x) = \dfrac{\pi}{2} + \tan^{-1} x$
3. Evaluate the derivative.
   (a) $\dfrac{d}{dx}[e^x]$ (b) $\dfrac{d}{dx}[7^x]$
   (c) $\dfrac{d}{dx}[\cos(e^x + 1)]$ (d) $\dfrac{d}{dx}[e^{3x-2}]$
4. Let $f(x) = e^{x^3+x}$. Use $f'(x)$ to verify that $f$ is one-to-one.

## EXERCISE SET 3.3 Graphing Utility

### FOCUS ON CONCEPTS

1. Let $f(x) = x^5 + x^3 + x$.
   (a) Show that $f$ is one-to-one and confirm that $f(1) = 3$.
   (b) Find $(f^{-1})'(3)$.
2. Let $f(x) = x^3 + 2e^x$.
   (a) Show that $f$ is one-to-one and confirm that $f(0) = 2$.
   (b) Find $(f^{-1})'(2)$.

**3–4** Find $(f^{-1})'(x)$ using Formula (2), and check your answer by differentiating $f^{-1}$ directly. ■

3. $f(x) = 2/(x + 3)$
4. $f(x) = \ln(2x + 1)$

**5–6** Determine whether the function $f$ is one-to-one by examining the sign of $f'(x)$. ■

5. (a) $f(x) = x^2 + 8x + 1$
   (b) $f(x) = 2x^5 + x^3 + 3x + 2$
   (c) $f(x) = 2x + \sin x$
   (d) $f(x) = \left(\frac{1}{2}\right)^x$
6. (a) $f(x) = x^3 + 3x^2 - 8$
   (b) $f(x) = x^5 + 8x^3 + 2x - 1$
   (c) $f(x) = \dfrac{x}{x+1}$
   (d) $f(x) = \log_b x, \quad 0 < b < 1$

**7–10** Find the derivative of $f^{-1}$ by using Formula (3), and check your result by differentiating implicitly. ■

**7.** $f(x) = 5x^3 + x - 7$

**8.** $f(x) = 1/x^2, \quad x > 0$

**9.** $f(x) = 2x^5 + x^3 + 1$

**10.** $f(x) = 5x - \sin 2x, \quad -\dfrac{\pi}{4} < x < \dfrac{\pi}{4}$

**FOCUS ON CONCEPTS**

**11.** Figure 0.4.8 is a "proof by picture" that the reflection of a point $P(a, b)$ about the line $y = x$ is the point $Q(b, a)$. Establish this result rigorously by completing each part.
(a) Prove that if $P$ is not on the line $y = x$, then $P$ and $Q$ are distinct, and the line $\overleftrightarrow{PQ}$ is perpendicular to the line $y = x$.
(b) Prove that if $P$ is not on the line $y = x$, the midpoint of segment $PQ$ is on the line $y = x$.
(c) Carefully explain what it means geometrically to reflect $P$ about the line $y = x$.
(d) Use the results of parts (a)–(c) to prove that $Q$ is the reflection of $P$ about the line $y = x$.

**12.** Prove that the reflection about the line $y = x$ of a line with slope $m, m \neq 0$, is a line with slope $1/m$. [*Hint:* Apply the result of the previous exercise to a pair of points on the line of slope $m$ and to a corresponding pair of points on the reflection of this line about the line $y = x$.]

**13.** Suppose that $f$ and $g$ are increasing functions. Determine which of the functions $f(x) + g(x)$, $f(x)g(x)$, and $f(g(x))$ must also be increasing.

**14.** Suppose that $f$ and $g$ are one-to-one functions. Determine which of the functions $f(x) + g(x)$, $f(x)g(x)$, and $f(g(x))$ must also be one-to-one.

**15–26** Find $dy/dx$. ■

**15.** $y = e^{7x}$

**16.** $y = e^{-5x^2}$

**17.** $y = x^3 e^x$

**18.** $y = e^{1/x}$

**19.** $y = \dfrac{e^x - e^{-x}}{e^x + e^{-x}}$

**20.** $y = \sin(e^x)$

**21.** $y = e^{x \tan x}$

**22.** $y = \dfrac{e^x}{\ln x}$

**23.** $y = e^{(x - e^{3x})}$

**24.** $y = \exp(\sqrt{1 + 5x^3})$

**25.** $y = \ln(1 - xe^{-x})$

**26.** $y = \ln(\cos e^x)$

**27–30** Find $f'(x)$ by Formula (7) and then by logarithmic differentiation. ■

**27.** $f(x) = 2^x$

**28.** $f(x) = 3^{-x}$

**29.** $f(x) = \pi^{\sin x}$

**30.** $f(x) = \pi^{x \tan x}$

**31–35** Find $dy/dx$ using the method of logarithmic differentiation. ■

**31.** $y = (x^3 - 2x)^{\ln x}$

**32.** $y = x^{\sin x}$

**33.** $y = (\ln x)^{\tan x}$

**34.** $y = (x^2 + 3)^{\ln x}$

**35.** $y = (\ln x)^{\ln x}$

**36.** (a) Explain why Formula (5) cannot be used to find $(d/dx)[x^x]$.
(b) Find this derivative by logarithmic differentiation.

**37–42** Find $dy/dx$ using any method. ■

**37.** $y = (x^3 - 2x^2 + 1)e^x$

**38.** $y = (2x^2 - 2x + 1)e^{2x}$

**39.** $y = (x^2 + \sqrt{x})3^x$

**40.** $y = (x^3 + \sqrt[3]{x})5^x$

**41.** $y = 4^{3 \sin x - e^x}$

**42.** $y = 2^{\cos x + \ln x}$

**43–58** Find $dy/dx$. ■

**43.** $y = \sin^{-1}(3x)$

**44.** $y = \cos^{-1}\left(\dfrac{x+1}{2}\right)$

**45.** $y = \sin^{-1}(1/x)$

**46.** $y = \cos^{-1}(\cos x)$

**47.** $y = \tan^{-1}(x^3)$

**48.** $y = \sec^{-1}(x^5)$

**49.** $y = (\tan x)^{-1}$

**50.** $y = \dfrac{1}{\tan^{-1} x}$

**51.** $y = e^x \sec^{-1} x$

**52.** $y = \ln(\cos^{-1} x)$

**53.** $y = \sin^{-1} x + \cos^{-1} x$

**54.** $y = x^2(\sin^{-1} x)^3$

**55.** $y = \sec^{-1} x + \csc^{-1} x$

**56.** $y = \csc^{-1}(e^x)$

**57.** $y = \cot^{-1}(\sqrt{x})$

**58.** $y = \sqrt{\cot^{-1} x}$

**59–62 True–False** Determine whether the statement is true or false. Explain your answer. ■

**59.** If a function $y = f(x)$ satisfies $dy/dx = y$, then $y = e^x$.

**60.** If $y = f(x)$ is a function such that $dy/dx$ is a rational function, then $f(x)$ is also a rational function.

**61.** $\dfrac{d}{dx}(\log_b |x|) = \dfrac{1}{x \ln b}$

**62.** We can conclude from the derivatives of $\sin^{-1} x$ and $\cos^{-1} x$ that $\sin^{-1} x + \cos^{-1} x$ is constant.

**63.** (a) Use Formula (2) to prove that

$$\frac{d}{dx}[\cot^{-1} x]\Big|_{x=0} = -1$$

(b) Use part (a) above, part (a) of Exercise 50 in Section 0.4, and the chain rule to show that

$$\frac{d}{dx}[\cot^{-1} x] = -\frac{1}{1 + x^2}$$

for $-\infty < x < +\infty$.
(c) Conclude from part (b) that

$$\frac{d}{dx}[\cot^{-1} u] = -\frac{1}{1 + u^2}\frac{du}{dx}$$

for $-\infty < u < +\infty$.

**64.** (a) Use part (c) of Exercise 50 in Section 0.4 and the chain rule to show that

$$\frac{d}{dx}[\csc^{-1} x] = -\frac{1}{|x|\sqrt{x^2 - 1}}$$

for $1 < |x|$.

(cont.)

(b) Conclude from part (a) that

$$\frac{d}{dx}[\csc^{-1} u] = -\frac{1}{|u|\sqrt{u^2-1}}\frac{du}{dx}$$

for $1 < |u|$.

(c) Use Equation (11) in Section 0.4 and parts (b) and (c) of Exercise 50 in that section to show that if $|x| \geq 1$, then $\sec^{-1} x + \csc^{-1} x = \pi/2$. Conclude from part (a) that

$$\frac{d}{dx}[\sec^{-1} x] = \frac{1}{|x|\sqrt{x^2-1}}$$

(d) Conclude from part (c) that

$$\frac{d}{dx}[\sec^{-1} u] = \frac{1}{|u|\sqrt{x^2-1}}\frac{du}{dx}$$

**65–66** Find $dy/dx$ by implicit differentiation. ■

**65.** $x^3 + x\tan^{-1} y = e^y$

**66.** $\sin^{-1}(xy) = \cos^{-1}(x-y)$

**67.** (a) Show that $f(x) = x^3 - 3x^2 + 2x$ is not one-to-one on $(-\infty, +\infty)$.

(b) Find the largest value of $k$ such that $f$ is one-to-one on the interval $(-k, k)$.

**68.** (a) Show that the function $f(x) = x^4 - 2x^3$ is not one-to-one on $(-\infty, +\infty)$.

(b) Find the smallest value of $k$ such that $f$ is one-to-one on the interval $[k, +\infty)$.

**69.** Let $f(x) = x^4 + x^3 + 1, 0 \leq x \leq 2$.

(a) Show that $f$ is one-to-one.

(b) Let $g(x) = f^{-1}(x)$ and define $F(x) = f(2g(x))$. Find an equation for the tangent line to $y = F(x)$ at $x = 3$.

**70.** Let $f(x) = \dfrac{\exp(4-x^2)}{x}, x > 0$.

(a) Show that $f$ is one-to-one.

(b) Let $g(x) = f^{-1}(x)$ and define $F(x) = f([g(x)]^2)$. Find $F'\left(\frac{1}{2}\right)$.

**71.** Show that for any constants $A$ and $k$, the function $y = Ae^{kt}$ satisfies the equation $dy/dt = ky$.

**72.** Show that for any constants $A$ and $B$, the function

$$y = Ae^{2x} + Be^{-4x}$$

satisfies the equation

$$y'' + 2y' - 8y = 0$$

**73.** Show that

(a) $y = xe^{-x}$ satisfies the equation $xy' = (1-x)y$

(b) $y = xe^{-x^2/2}$ satisfies the equation $xy' = (1-x^2)y$.

**74.** Show that the rate of change of $y = 100e^{-0.2x}$ with respect to $x$ is proportional to $y$.

**75.** Suppose that the percentage of U.S. households with broadband Internet access is modeled by the equation

$$P(t) = \frac{5300}{53 + 47e^{-0.182t}}$$

where $P(t)$ is the percentage $t$ years after an initial survey result made in the year 2007.

(a) Use a graphing utility to graph the function $P(t)$.

(b) In words, explain what happens to the percentage over time. Check your conclusion by finding $\lim_{t\to+\infty} P(t)$.

(c) In words, what happens to the *rate* of population growth over time? Check your conclusion by graphing $P'(t)$.

**76.** Suppose that the population of oxygen-dependent bacteria in a pond is modeled by the equation

$$P(t) = \frac{60}{5 + 7e^{-t}}$$

where $P(t)$ is the population (in billions) $t$ days after an initial observation at time $t = 0$.

(a) Use a graphing utility to graph the function $P(t)$.

(b) In words, explain what happens to the population over time. Check your conclusion by finding $\lim_{t\to+\infty} P(t)$.

(c) In words, what happens to the *rate* of population growth over time? Check your conclusion by graphing $P'(t)$.

**77–82** Find the limit by interpreting the expression as an appropriate derivative. ■

**77.** $\lim_{x\to 0} \dfrac{e^{3x}-1}{x}$

**78.** $\lim_{x\to 0} \dfrac{\exp(x^2)-1}{x}$

**79.** $\lim_{h\to 0} \dfrac{10^h - 1}{h}$

**80.** $\lim_{h\to 0} \dfrac{\tan^{-1}(1+h) - \pi/4}{h}$

**81.** $\lim_{\Delta x\to 0} \dfrac{9\left[\sin^{-1}\left(\frac{\sqrt{3}}{2} + \Delta x\right)\right]^2 - \pi^2}{\Delta x}$

**82.** $\lim_{w\to 2} \dfrac{3\sec^{-1} w - \pi}{w-2}$

**83.** Suppose that a steel ball bearing is released within a vat of fluid and begins to sink. According to one model, the speed $v(t)$ (in m/s) of the ball bearing $t$ seconds after its release is given by the formula

$$v(t) = \frac{9.8}{k}(1 - e^{-kt})$$

where $k$ is a positive constant that corresponds to the resistance the fluid offers against the motion of the bearing. (The smaller the value of $k$, the weaker will be the resistance.) For $t$ fixed, determine the limiting value of the speed as $k \to 0^+$, and give a physical interpretation of the limit.

## ✔ QUICK CHECK ANSWERS 3.3

**1.** $\frac{1}{5}$ **2.** (a) yes (b) no (c) no (d) yes **3.** (a) $e^x$ (b) $7^x \ln 7$ (c) $-e^x \sin(e^x + 1)$ (d) $3e^{3x-2}$

**4.** $f'(x) = e^{x^3+x} \cdot (3x^2 + 1) > 0$ for all $x$

# 3.4 RELATED RATES

*In this section we will study related rates problems. In such problems one tries to find the rate at which some quantity is changing by relating the quantity to other quantities whose rates of change are known.*

## DIFFERENTIATING EQUATIONS TO RELATE RATES

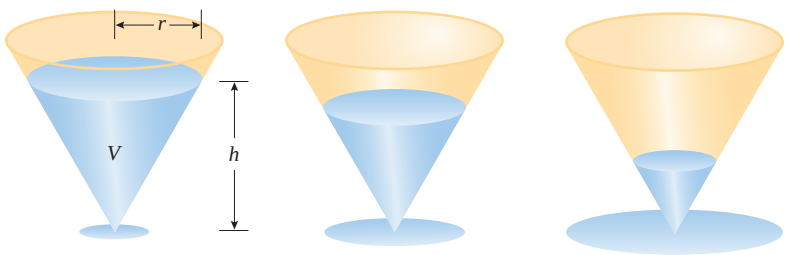
Figure 3.4.1 shows a liquid draining through a conical filter. As the liquid drains, its volume $V$, height $h$, and radius $r$ are functions of the elapsed time $t$, and at each instant these variables are related by the equation

$$V = \frac{\pi}{3} r^2 h$$

If we were interested in finding the rate of change of the volume $V$ with respect to the time $t$, we could begin by differentiating both sides of this equation with respect to $t$ to obtain

$$\frac{dV}{dt} = \frac{\pi}{3}\left[r^2 \frac{dh}{dt} + h\left(2r\frac{dr}{dt}\right)\right] = \frac{\pi}{3}\left(r^2\frac{dh}{dt} + 2rh\frac{dr}{dt}\right)$$

Thus, to find $dV/dt$ at a specific time $t$ from this equation we would need to have values for $r$, $h$, $dh/dt$, and $dr/dt$ at that time. This is called a ***related rates problem*** because the goal is to find an unknown rate of change by *relating* it to other variables whose values and whose rates of change at time $t$ are known or can be found in some way. Let us begin with a simple example.



▶ Figure 3.4.1

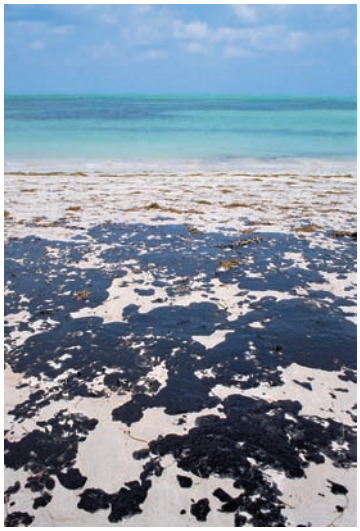
▶ **Example 1** Suppose that $x$ and $y$ are differentiable functions of $t$ and are related by the equation $y = x^3$. Find $dy/dt$ at time $t = 1$ if $x = 2$ and $dx/dt = 4$ at time $t = 1$.

***Solution.*** Using the chain rule to differentiate both sides of the equation $y = x^3$ with respect to $t$ yields

$$\frac{dy}{dt} = \frac{d}{dt}[x^3] = 3x^2\frac{dx}{dt}$$

Thus, the value of $dy/dt$ at time $t = 1$ is

$$\left.\frac{dy}{dt}\right|_{t=1} = 3(2)^2 \left.\frac{dx}{dt}\right|_{t=1} = 12 \cdot 4 = 48 \quad ◀$$



Arni Katz/Phototake

*Oil spill from a ruptured tanker.*

**▶ Example 2** Assume that oil spilled from a ruptured tanker spreads in a circular pattern whose radius increases at a constant rate of 2 ft/s. How fast is the area of the spill increasing when the radius of the spill is 60 ft?

***Solution.*** Let

$t$ = number of seconds elapsed from the time of the spill
$r$ = radius of the spill in feet after $t$ seconds
$A$ = area of the spill in square feet after $t$ seconds

(Figure 3.4.2). We know the rate at which the radius is increasing, and we want to find the rate at which the area is increasing at the instant when $r = 60$; that is, we want to find

$$\left.\frac{dA}{dt}\right|_{r=60} \quad \text{given that} \quad \frac{dr}{dt} = 2 \text{ ft/s}$$

This suggests that we look for an equation relating $A$ and $r$ that we can differentiate with respect to $t$ to produce a relationship between $dA/dt$ and $dr/dt$. But $A$ is the area of a circle of radius $r$, so

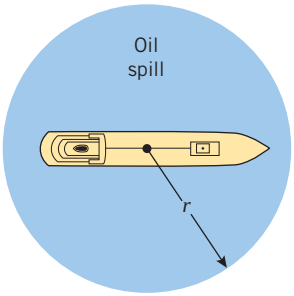
$$A = \pi r^2 \tag{1}$$

Differentiating both sides of (1) with respect to $t$ yields

$$\frac{dA}{dt} = 2\pi r \frac{dr}{dt} \tag{2}$$

Thus, when $r = 60$ the area of the spill is increasing at the rate of

$$\left.\frac{dA}{dt}\right|_{r=60} = 2\pi(60)(2) = 240\pi \text{ ft}^2/\text{s} \approx 754 \text{ ft}^2/\text{s} \quad ◀$$



▲ **Figure 3.4.2**

With some minor variations, the method used in Example 2 can be used to solve a variety of related rates problems. We can break the method down into five steps.

***A Strategy for Solving Related Rates Problems***

**Step 1.** Assign letters to all quantities that vary with time and any others that seem relevant to the problem. Give a definition for each letter.

**Step 2.** Identify the rates of change that are known and the rate of change that is to be found. Interpret each rate as a derivative.

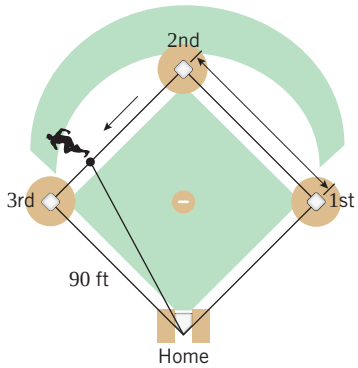
**Step 3.** Find an equation that relates the variables whose rates of change were identified in Step 2. To do this, it will often be helpful to draw an appropriately labeled figure that illustrates the relationship.

**Step 4.** Differentiate both sides of the equation obtained in Step 3 with respect to time to produce a relationship between the known rates of change and the unknown rate of change.

**Step 5.** *After* completing Step 4, substitute all known values for the rates of change and the variables, and then solve for the unknown rate of change.

**WARNING**

We have italicized the word "After" in Step 5 because it is a common error to substitute numerical values before performing the differentiation. For instance, in Example 2 had we substituted the known value of $r = 60$ in (1) before differentiating, we would have obtained $dA/dt = 0$, which is obviously incorrect.



▲ Figure 3.4.3

**Example 3** A baseball diamond is a square whose sides are 90 ft long (Figure 3.4.3). Suppose that a player running from second base to third base has a speed of 30 ft/s at the instant when he is 20 ft from third base. At what rate is the player's distance from home plate changing at that instant?

***Solution.*** We are given a constant speed with which the player is approaching third base, and we want to find the rate of change of the distance between the player and home plate at a particular instant. Thus, let

$t$ = number of seconds since the player left second base
$x$ = distance in feet from the player to third base
$y$ = distance in feet from the player to home plate

(Figure 3.4.4). Thus, we want to find

$$\left.\frac{dy}{dt}\right|_{x=20} \quad \text{given that} \quad \left.\frac{dx}{dt}\right|_{x=20} = -30 \text{ ft/s}$$

As suggested by Figure 3.4.4, an equation relating the variables $x$ and $y$ can be obtained using the Theorem of Pythagoras:

$$x^2 + 90^2 = y^2 \tag{3}$$

Differentiating both sides of this equation with respect to $t$ yields

$$2x\frac{dx}{dt} = 2y\frac{dy}{dt}$$

from which we obtain

$$\frac{dy}{dt} = \frac{x}{y}\frac{dx}{dt} \tag{4}$$

When $x = 20$, it follows from (3) that

$$y = \sqrt{20^2 + 90^2} = \sqrt{8500} = 10\sqrt{85}$$

so that (4) yields

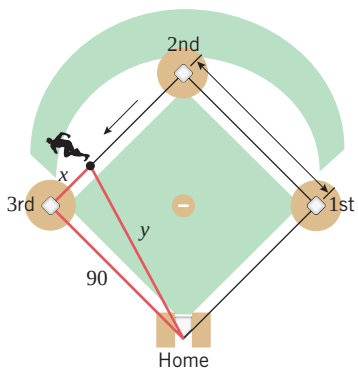
$$\left.\frac{dy}{dt}\right|_{x=20} = \frac{20}{10\sqrt{85}}(-30) = -\frac{60}{\sqrt{85}} \approx -6.51 \text{ ft/s}$$

The negative sign in the answer tells us that $y$ is decreasing, which makes sense physically from Figure 3.4.4. ◄

The quantity

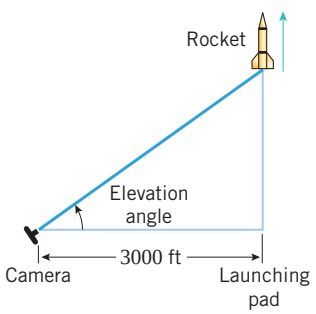
$$\left.\frac{dx}{dt}\right|_{x=20}$$

is negative because $x$ is decreasing with respect to $t$.



▲ Figure 3.4.4

**Example 4** In Figure 3.4.5 we have shown a camera mounted at a point 3000 ft from the base of a rocket launching pad. If the rocket is rising vertically at 880 ft/s when it is 4000 ft above the launching pad, how fast must the camera elevation angle change at that instant to keep the camera aimed at the rocket?

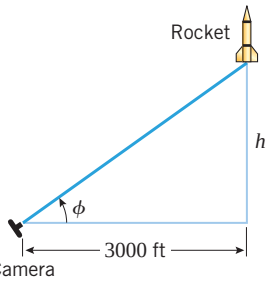


▲ Figure 3.4.5

***Solution.*** Let

$t$ = number of seconds elapsed from the time of launch
$\phi$ = camera elevation angle in radians after $t$ seconds
$h$ = height of the rocket in feet after $t$ seconds

(Figure 3.4.6). At each instant the rate at which the camera elevation angle must change



▲ Figure 3.4.6

is $d\phi/dt$, and the rate at which the rocket is rising is $dh/dt$. We want to find

$$\left.\frac{d\phi}{dt}\right|_{h=4000} \quad \text{given that} \quad \left.\frac{dh}{dt}\right|_{h=4000} = 880 \text{ ft/s}$$

From Figure 3.4.6 we see that

$$\tan\phi = \frac{h}{3000} \tag{5}$$

Differentiating both sides of (5) with respect to $t$ yields

$$(\sec^2\phi)\frac{d\phi}{dt} = \frac{1}{3000}\frac{dh}{dt} \tag{6}$$

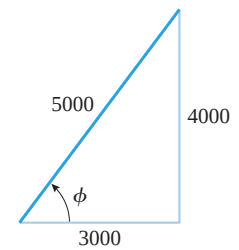
When $h = 4000$, it follows that

$$(\sec\phi)\big|_{h=4000} = \frac{5000}{3000} = \frac{5}{3}$$

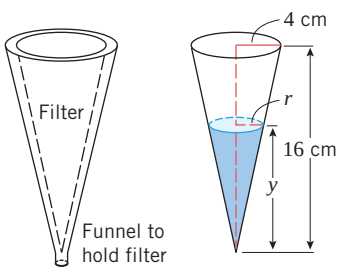
(see Figure 3.4.7), so that from (6)

$$\left(\frac{5}{3}\right)^2 \left.\frac{d\phi}{dt}\right|_{h=4000} = \frac{1}{3000}\cdot 880 = \frac{22}{75}$$

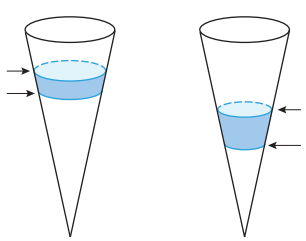
$$\left.\frac{d\phi}{dt}\right|_{h=4000} = \frac{22}{75}\cdot\frac{9}{25} = \frac{66}{625} \approx 0.11 \text{ rad/s} \approx 6.05 \text{ deg/s} \quad \blacktriangleleft$$



▲ Figure 3.4.7



▲ Figure 3.4.8



The same volume has drained, but the change in height is greater near the bottom than near the top.

▲ Figure 3.4.9

► **Example 5** Suppose that liquid is to be cleared of sediment by allowing it to drain through a conical filter that is 16 cm high and has a radius of 4 cm at the top (Figure 3.4.8). Suppose also that the liquid is forced out of the cone at a constant rate of 2 $cm^3$/min.

(a) Do you think that the depth of the liquid will decrease at a constant rate? Give a verbal argument that justifies your conclusion.

(b) Find a formula that expresses the rate at which the depth of the liquid is changing in terms of the depth, and use that formula to determine whether your conclusion in part (a) is correct.

(c) At what rate is the depth of the liquid changing at the instant when the liquid in the cone is 8 cm deep?

***Solution (a).*** For the volume of liquid to decrease by a *fixed amount*, it requires a greater decrease in depth when the cone is close to empty than when it is almost full (Figure 3.4.9). This suggests that for the volume to decrease at a constant rate, the depth must decrease at an increasing rate.

***Solution (b).*** Let

$t$ = time elapsed from the initial observation (min)
$V$ = volume of liquid in the cone at time $t$ ($cm^3$)
$y$ = depth of the liquid in the cone at time $t$ (cm)
$r$ = radius of the liquid surface at time $t$ (cm)

(Figure 3.4.8). At each instant the rate at which the volume of liquid is changing is $dV/dt$, and the rate at which the depth is changing is $dy/dt$. We want to express $dy/dt$ in terms of $y$ given that $dV/dt$ has a constant value of $dV/dt = -2$. (We must use a minus sign here because $V$ *decreases* as $t$ increases.)

From the formula for the volume of a cone, the volume $V$, the radius $r$, and the depth $y$ are related by

$$V = \tfrac{1}{3}\pi r^2 y \tag{7}$$

If we differentiate both sides of (7) with respect to $t$, the right side will involve the quantity $dr/dt$. Since we have no direct information about $dr/dt$, it is desirable to eliminate $r$ from (7) before differentiating. This can be done using similar triangles. From Figure 3.4.8 we see that

$$\frac{r}{y} = \frac{4}{16} \quad \text{or} \quad r = \frac{1}{4}y$$

Substituting this expression in (7) gives

$$V = \frac{\pi}{48}y^3 \tag{8}$$

Differentiating both sides of (8) with respect to $t$ we obtain

$$\frac{dV}{dt} = \frac{\pi}{48}\left(3y^2\frac{dy}{dt}\right)$$

or

$$\frac{dy}{dt} = \frac{16}{\pi y^2}\frac{dV}{dt} = \frac{16}{\pi y^2}(-2) = -\frac{32}{\pi y^2} \tag{9}$$

which expresses $dy/dt$ in terms of $y$. The minus sign tells us that $y$ is decreasing with time, and

$$\left|\frac{dy}{dt}\right| = \frac{32}{\pi y^2}$$

tells us how fast $y$ is decreasing. From this formula we see that $|dy/dt|$ increases as $y$ decreases, which confirms our conjecture in part (a) that the depth of the liquid decreases more quickly as the liquid drains through the filter.

***Solution (c).*** The rate at which the depth is changing when the depth is 8 cm can be obtained from (9) with $y = 8$:

$$\left.\frac{dy}{dt}\right|_{y=8} = -\frac{32}{\pi(8^2)} = -\frac{1}{2\pi} \approx -0.16 \text{ cm/min} \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 3.4 (See page 211 for answers.)

1. If $A = x^2$ and $\dfrac{dx}{dt} = 3$, find $\left.\dfrac{dA}{dt}\right|_{x=10}$.
2. If $A = x^2$ and $\dfrac{dA}{dt} = 3$, find $\left.\dfrac{dx}{dt}\right|_{x=10}$.
3. A 10-foot ladder stands on a horizontal floor and leans against a vertical wall. Use $x$ to denote the distance along the floor from the wall to the foot of the ladder, and use $y$ to denote the distance along the wall from the floor to the top of the ladder. If the foot of the ladder is dragged away from the wall, find an equation that relates rates of change of $x$ and $y$ with respect to time.
4. Suppose that a block of ice in the shape of a right circular cylinder melts so that it retains its cylindrical shape. Find an equation that relates the rates of change of the volume ($V$), height ($h$), and radius ($r$) of the block of ice.

## EXERCISE SET 3.4

**1–4** Both $x$ and $y$ denote functions of $t$ that are related by the given equation. Use this equation and the given derivative information to find the specified derivative. ■

1. Equation: $y = 3x + 5$.
   (a) Given that $dx/dt = 2$, find $dy/dt$ when $x = 1$.
   (b) Given that $dy/dt = -1$, find $dx/dt$ when $x = 0$.
2. Equation: $x + 4y = 3$.
   (a) Given that $dx/dt = 1$, find $dy/dt$ when $x = 2$.
   (b) Given that $dy/dt = 4$, find $dx/dt$ when $x = 3$.
3. Equation: $4x^2 + 9y^2 = 1$.
   (a) Given that $dx/dt = 3$, find $dy/dt$ when $(x, y) = \left(\frac{1}{2\sqrt{2}}, \frac{1}{3\sqrt{2}}\right)$.

(cont.)

(b) Given that $dy/dt = 8$, find $dx/dt$ when $(x, y) = \left(\frac{1}{3}, -\frac{\sqrt{5}}{9}\right)$.

**4.** Equation: $x^2 + y^2 = 2x + 4y$.
(a) Given that $dx/dt = -5$, find $dy/dt$ when $(x, y) = (3, 1)$.
(b) Given that $dy/dt = 6$, find $dx/dt$ when $(x, y) = (1 + \sqrt{2}, 2 + \sqrt{3})$.

**FOCUS ON CONCEPTS**

**5.** Let $A$ be the area of a square whose sides have length $x$, and assume that $x$ varies with the time $t$.
(a) Draw a picture of the square with the labels $A$ and $x$ placed appropriately.
(b) Write an equation that relates $A$ and $x$.
(c) Use the equation in part (b) to find an equation that relates $dA/dt$ and $dx/dt$.
(d) At a certain instant the sides are 3 ft long and increasing at a rate of 2 ft/min. How fast is the area increasing at that instant?

**6.** In parts (a)–(d), let $A$ be the area of a circle of radius $r$, and assume that $r$ increases with the time $t$.
(a) Draw a picture of the circle with the labels $A$ and $r$ placed appropriately.
(b) Write an equation that relates $A$ and $r$.
(c) Use the equation in part (b) to find an equation that relates $dA/dt$ and $dr/dt$.
(d) At a certain instant the radius is 5 cm and increasing at the rate of 2 cm/s. How fast is the area increasing at that instant?

**7.** Let $V$ be the volume of a cylinder having height $h$ and radius $r$, and assume that $h$ and $r$ vary with time.
(a) How are $dV/dt$, $dh/dt$, and $dr/dt$ related?
(b) At a certain instant, the height is 6 in and increasing at 1 in/s, while the radius is 10 in and decreasing at 1 in/s. How fast is the volume changing at that instant? Is the volume increasing or decreasing at that instant?

**8.** Let $l$ be the length of a diagonal of a rectangle whose sides have lengths $x$ and $y$, and assume that $x$ and $y$ vary with time.
(a) How are $dl/dt$, $dx/dt$, and $dy/dt$ related?
(b) If $x$ increases at a constant rate of $\frac{1}{2}$ ft/s and $y$ decreases at a constant rate of $\frac{1}{4}$ ft/s, how fast is the size of the diagonal changing when $x = 3$ ft and $y = 4$ ft? Is the diagonal increasing or decreasing at that instant?

**9.** Let $\theta$ (in radians) be an acute angle in a right triangle, and let $x$ and $y$, respectively, be the lengths of the sides adjacent to and opposite $\theta$. Suppose also that $x$ and $y$ vary with time.
(a) How are $d\theta/dt$, $dx/dt$, and $dy/dt$ related?
(b) At a certain instant, $x = 2$ units and is increasing at 1 unit/s, while $y = 2$ units and is decreasing at $\frac{1}{4}$ unit/s. How fast is $\theta$ changing at that instant? Is $\theta$ increasing or decreasing at that instant?

**10.** Suppose that $z = x^3y^2$, where both $x$ and $y$ are changing with time. At a certain instant when $x = 1$ and $y = 2$, $x$ is decreasing at the rate of 2 units/s, and $y$ is increasing at the rate of 3 units/s. How fast is $z$ changing at this instant? Is $z$ increasing or decreasing?

**11.** The minute hand of a certain clock is 4 in long. Starting from the moment when the hand is pointing straight up, how fast is the area of the sector that is swept out by the hand increasing at any instant during the next revolution of the hand?

**12.** A stone dropped into a still pond sends out a circular ripple whose radius increases at a constant rate of 3 ft/s. How rapidly is the area enclosed by the ripple increasing at the end of 10 s?

**13.** Oil spilled from a ruptured tanker spreads in a circle whose area increases at a constant rate of 6 $\text{mi}^2/\text{h}$. How fast is the radius of the spill increasing when the area is 9 $\text{mi}^2$?

**14.** A spherical balloon is inflated so that its volume is increasing at the rate of 3 $\text{ft}^3/\text{min}$. How fast is the diameter of the balloon increasing when the radius is 1 ft?

**15.** A spherical balloon is to be deflated so that its radius decreases at a constant rate of 15 cm/min. At what rate must air be removed when the radius is 9 cm?

**16.** A 17 ft ladder is leaning against a wall. If the bottom of the ladder is pulled along the ground away from the wall at a constant rate of 5 ft/s, how fast will the top of the ladder be moving down the wall when it is 8 ft above the ground?

**17.** A 13 ft ladder is leaning against a wall. If the top of the ladder slips down the wall at a rate of 2 ft/s, how fast will the foot be moving away from the wall when the top is 5 ft above the ground?

**18.** A 10 ft plank is leaning against a wall. If at a certain instant the bottom of the plank is 2 ft from the wall and is being pushed toward the wall at the rate of 6 in/s, how fast is the acute angle that the plank makes with the ground increasing?

**19.** A softball diamond is a square whose sides are 60 ft long. Suppose that a player running from first to second base has a speed of 25 ft/s at the instant when she is 10 ft from second base. At what rate is the player's distance from home plate changing at that instant?

**20.** A rocket, rising vertically, is tracked by a radar station that is on the ground 5 mi from the launchpad. How fast is the rocket rising when it is 4 mi high and its distance from the radar station is increasing at a rate of 2000 mi/h?

**21.** For the camera and rocket shown in Figure 3.4.5, at what rate is the camera-to-rocket distance changing when the rocket is 4000 ft up and rising vertically at 880 ft/s?

**22.** For the camera and rocket shown in Figure 3.4.5, at what rate is the rocket rising when the elevation angle is $\pi/4$ radians and increasing at a rate of 0.2 rad/s?

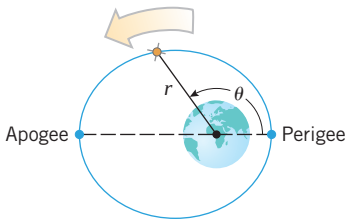
**23.** A satellite is in an elliptical orbit around the Earth. Its distance $r$ (in miles) from the center of the Earth is given by

$$r = \frac{4995}{1 + 0.12\cos\theta}$$

where $\theta$ is the angle measured from the point on the orbit nearest the Earth's surface (see the accompanying figure).

(a) Find the altitude of the satellite at ***perigee*** (the point nearest the surface of the Earth) and at ***apogee*** (the point farthest from the surface of the Earth). Use 3960 mi as the radius of the Earth.

(b) At the instant when $\theta$ is 120°, the angle $\theta$ is increasing at the rate of 2.7°/min. Find the altitude of the satellite and the rate at which the altitude is changing at this instant. Express the rate in units of mi/min.

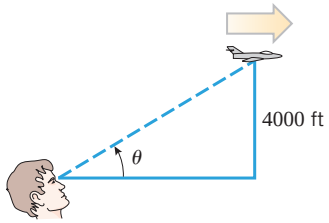


◀ **Figure Ex-23**

**24.** An aircraft is flying horizontally at a constant height of 4000 ft above a fixed observation point (see the accompanying figure). At a certain instant the angle of elevation $\theta$ is 30° and decreasing, and the speed of the aircraft is 300 mi/h.

(a) How fast is $\theta$ decreasing at this instant? Express the result in units of deg/s.

(b) How fast is the distance between the aircraft and the observation point changing at this instant? Express the result in units of ft/s. Use 1 mi = 5280 ft.



◀ **Figure Ex-24**

**25.** A conical water tank with vertex down has a radius of 10 ft at the top and is 24 ft high. If water flows into the tank at a rate of 20 ft$^3$/min, how fast is the depth of the water increasing when the water is 16 ft deep?

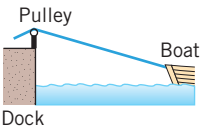
**26.** Grain pouring from a chute at the rate of 8 ft$^3$/min forms a conical pile whose height is always twice its radius. How fast is the height of the pile increasing at the instant when the pile is 6 ft high?

**27.** Sand pouring from a chute forms a conical pile whose height is always equal to the diameter. If the height increases at a constant rate of 5 ft/min, at what rate is sand pouring from the chute when the pile is 10 ft high?

**28.** Wheat is poured through a chute at the rate of 10 ft$^3$/min and falls in a conical pile whose bottom radius is always half the altitude. How fast will the circumference of the base be increasing when the pile is 8 ft high?

**29.** An aircraft is climbing at a 30° angle to the horizontal. How fast is the aircraft gaining altitude if its speed is 500 mi/h?

**30.** A boat is pulled into a dock by means of a rope attached to a pulley on the dock (see the accompanying figure). The rope is attached to the bow of the boat at a point 10 ft below the pulley. If the rope is pulled through the pulley at a rate of 20 ft/min, at what rate will the boat be approaching the dock when 125 ft of rope is out?



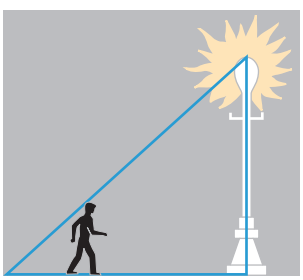
◀ **Figure Ex-30**

**31.** For the boat in Exercise 30, how fast must the rope be pulled if we want the boat to approach the dock at a rate of 12 ft/min at the instant when 125 ft of rope is out?

**32.** A man 6 ft tall is walking at the rate of 3 ft/s toward a streetlight 18 ft high (see the accompanying figure).

(a) At what rate is his shadow length changing?

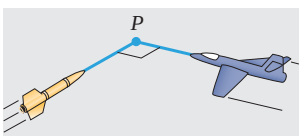
(b) How fast is the tip of his shadow moving?



◀ **Figure Ex-32**

**33.** A beacon that makes one revolution every 10 s is located on a ship anchored 4 kilometers from a straight shoreline. How fast is the beam moving along the shoreline when it makes an angle of 45° with the shore?

**34.** An aircraft is flying at a constant altitude with a constant speed of 600 mi/h. An antiaircraft missile is fired on a straight line perpendicular to the flight path of the aircraft so that it will hit the aircraft at a point $P$ (see the accompanying figure). At the instant the aircraft is 2 mi from the impact point $P$ the missile is 4 mi from $P$ and flying at 1200 mi/h. At that instant, how rapidly is the distance between missile and aircraft decreasing?



◀ **Figure Ex-34**

**35.** Solve Exercise 34 under the assumption that the angle between the flight paths is 120° instead of the assumption that the paths are perpendicular. [*Hint:* Use the law of cosines.]

**36.** A police helicopter is flying due north at 100 mi/h and at a constant altitude of $\frac{1}{2}$ mi. Below, a car is traveling west on a highway at 75 mi/h. At the moment the helicopter crosses over the highway the car is 2 mi east of the helicopter.
(a) How fast is the distance between the car and helicopter changing at the moment the helicopter crosses the highway?
(b) Is the distance between the car and helicopter increasing or decreasing at that moment?

**37.** A particle is moving along the curve whose equation is

$$\frac{xy^3}{1+y^2} = \frac{8}{5}$$

Assume that the $x$-coordinate is increasing at the rate of 6 units/s when the particle is at the point $(1, 2)$.
(a) At what rate is the $y$-coordinate of the point changing at that instant?
(b) Is the particle rising or falling at that instant?

**38.** A point $P$ is moving along the curve whose equation is $y = \sqrt{x^3 + 17}$. When $P$ is at $(2, 5)$, $y$ is increasing at the rate of 2 units/s. How fast is $x$ changing?

**39.** A point $P$ is moving along the line whose equation is $y = 2x$. How fast is the distance between $P$ and the point $(3, 0)$ changing at the instant when $P$ is at $(3, 6)$ if $x$ is decreasing at the rate of 2 units/s at that instant?

**40.** A point $P$ is moving along the curve whose equation is $y = \sqrt{x}$. Suppose that $x$ is increasing at the rate of 4 units/s when $x = 3$.
(a) How fast is the distance between $P$ and the point $(2, 0)$ changing at this instant?
(b) How fast is the angle of inclination of the line segment from $P$ to $(2, 0)$ changing at this instant?

**41.** A particle is moving along the curve $y = x/(x^2 + 1)$. Find all values of $x$ at which the rate of change of $x$ with respect to time is three times that of $y$. [Assume that $dx/dt$ is never zero.]

**42.** A particle is moving along the curve $16x^2 + 9y^2 = 144$. Find all points $(x, y)$ at which the rates of change of $x$ and $y$ with respect to time are equal. [Assume that $dx/dt$ and $dy/dt$ are never both zero at the same point.]

**43.** The ***thin lens equation*** in physics is

$$\frac{1}{s} + \frac{1}{S} = \frac{1}{f}$$

where $s$ is the object distance from the lens, $S$ is the image distance from the lens, and $f$ is the focal length of the lens. Suppose that a certain lens has a focal length of 6 cm and that an object is moving toward the lens at the rate of 2 cm/s. How fast is the image distance changing at the instant when the object is 10 cm from the lens? Is the image moving away from the lens or toward the lens?

**44.** Water is stored in a cone-shaped reservoir (vertex down). Assuming the water evaporates at a rate proportional to the surface area exposed to the air, show that the depth of the water will decrease at a constant rate that does not depend on the dimensions of the reservoir.

**45.** A meteor enters the Earth's atmosphere and burns up at a rate that, at each instant, is proportional to its surface area. Assuming that the meteor is always spherical, show that the radius decreases at a constant rate.

**46.** On a certain clock the minute hand is 4 in long and the hour hand is 3 in long. How fast is the distance between the tips of the hands changing at 9 o'clock?

**47.** Coffee is poured at a uniform rate of 20 $\text{cm}^3/\text{s}$ into a cup whose inside is shaped like a truncated cone (see the accompanying figure). If the upper and lower radii of the cup are 4 cm and 2 cm and the height of the cup is 6 cm, how fast will the coffee level be rising when the coffee is halfway up? [*Hint:* Extend the cup downward to form a cone.]

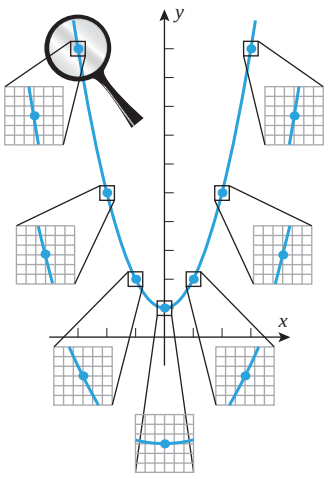
◀ **Figure Ex-47**

## ✔ QUICK CHECK ANSWERS 3.4

**1.** 60 **2.** $\frac{3}{20}$ **3.** $x\frac{dx}{dt} + y\frac{dy}{dt} = 0$ **4.** $\frac{dV}{dt} = 2\pi rh\frac{dr}{dt} + \pi r^2\frac{dh}{dt}$

# 3.5 LOCAL LINEAR APPROXIMATION; DIFFERENTIALS

*In this section we will show how derivatives can be used to approximate nonlinear functions by linear functions. Also, up to now we have been interpreting $dy/dx$ as a single entity representing the derivative. In this section we will define the quantities $dx$ and $dy$ themselves, thereby allowing us to interpret $dy/dx$ as an actual ratio.*



Magnifying portions of the graph of $y = x^2 + 1$

▲ Figure 3.5.1

Recall from Section 2.2 that if a function $f$ is differentiable at $x_0$, then a sufficiently magnified portion of the graph of $f$ centered at the point $P(x_0, f(x_0))$ takes on the appearance of a straight line segment. Figure 3.5.1 illustrates this at several points on the graph of $y = x^2 + 1$. For this reason, a function that is differentiable at $x_0$ is sometimes said to be ***locally linear*** at $x_0$.

The line that best approximates the graph of $f$ in the vicinity of $P(x_0, f(x_0))$ is the tangent line to the graph of $f$ at $x_0$, given by the equation

$$y = f(x_0) + f'(x_0)(x - x_0)$$

[see Formula (3) of Section 2.2]. Thus, for values of $x$ near $x_0$ we can approximate values of $f(x)$ by

$$f(x) \approx f(x_0) + f'(x_0)(x - x_0) \tag{1}$$

This is called the ***local linear approximation*** of $f$ at $x_0$. This formula can also be expressed in terms of the increment $\Delta x = x - x_0$ as

$$f(x_0 + \Delta x) \approx f(x_0) + f'(x_0)\Delta x \tag{2}$$

## ▶ Example 1

(a) Find the local linear approximation of $f(x) = \sqrt{x}$ at $x_0 = 1$.

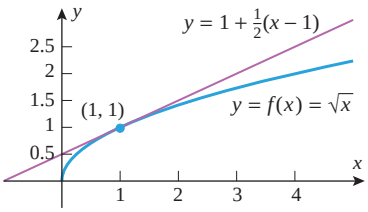
(b) Use the local linear approximation obtained in part (a) to approximate $\sqrt{1.1}$, and compare your approximation to the result produced directly by a calculating utility.

***Solution (a).*** Since $f'(x) = 1/(2\sqrt{x})$, it follows from (1) that the local linear approximation of $\sqrt{x}$ at a point $x_0$ is

$$\sqrt{x} \approx \sqrt{x_0} + \frac{1}{2\sqrt{x_0}}(x - x_0)$$

Thus, the local linear approximation at $x_0 = 1$ is

$$\sqrt{x} \approx 1 + \tfrac{1}{2}(x - 1) \tag{3}$$



▲ Figure 3.5.2

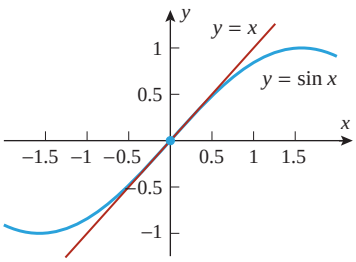
The graphs of $y = \sqrt{x}$ and the local linear approximation $y = 1 + \frac{1}{2}(x - 1)$ are shown in Figure 3.5.2.

***Solution (b).*** Applying (3) with $x = 1.1$ yields

$$\sqrt{1.1} \approx 1 + \tfrac{1}{2}(1.1 - 1) = 1.05$$

Since the tangent line $y = 1 + \frac{1}{2}(x - 1)$ in Figure 3.5.2 lies above the graph of $f(x) = \sqrt{x}$, we would expect this approximation to be slightly too large. This expectation is confirmed by the calculator approximation $\sqrt{1.1} \approx 1.04881$. ◀

Examples 1 and 2 illustrate important ideas and are not meant to suggest that you should use local linear approximations for computations that your calculating utility can perform. The main application of local linear approximation is in modeling problems where it is useful to replace complicated functions by simpler ones.



▲ Figure 3.5.3

### ▶ Example 2

(a) Find the local linear approximation of $f(x) = \sin x$ at $x_0 = 0$.

(b) Use the local linear approximation obtained in part (a) to approximate $\sin 2^\circ$, and compare your approximation to the result produced directly by your calculating device.

***Solution (a).*** Since $f'(x) = \cos x$, it follows from (1) that the local linear approximation of $\sin x$ at a point $x_0$ is

$$\sin x \approx \sin x_0 + (\cos x_0)(x - x_0)$$

Thus, the local linear approximation at $x_0 = 0$ is

$$\sin x \approx \sin 0 + (\cos 0)(x - 0)$$

which simplifies to

$$\sin x \approx x \tag{4}$$

***Solution (b).*** The variable $x$ in (4) is in radian measure, so we must first convert $2^\circ$ to radians before we can apply this approximation. Since

$$2^\circ = 2\left(\frac{\pi}{180}\right) = \frac{\pi}{90} \approx 0.0349066 \text{ radian}$$

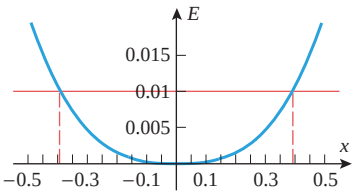
it follows from (4) that $\sin 2^\circ \approx 0.0349066$. Comparing the two graphs in Figure 3.5.3, we would expect this approximation to be slightly larger than the exact value. The calculator approximation $\sin 2^\circ \approx 0.0348995$ shows that this is indeed the case. ◀

## ERROR IN LOCAL LINEAR APPROXIMATIONS

As a general rule, the accuracy of the local linear approximation to $f(x)$ at $x_0$ will deteriorate as $x$ gets progressively farther from $x_0$. To illustrate this for the approximation $\sin x \approx x$ in Example 2, let us graph the function

$$E(x) = |\sin x - x|$$

which is the absolute value of the error in the approximation (Figure 3.5.4).



$E(x) = |\sin x - x|$

▲ Figure 3.5.4

In Figure 3.5.4, the graph shows how the absolute error in the local linear approximation of $\sin x$ increases as $x$ moves progressively farther from 0 in either the positive or negative direction. The graph also tells us that for values of $x$ between the two vertical lines, the absolute error does not exceed 0.01. Thus, for example, we could use the local linear approximation $\sin x \approx x$ for all values of $x$ in the interval $-0.35 < x < 0.35$ (radians) with confidence that the approximation is within $\pm 0.01$ of the exact value.

## DIFFERENTIALS

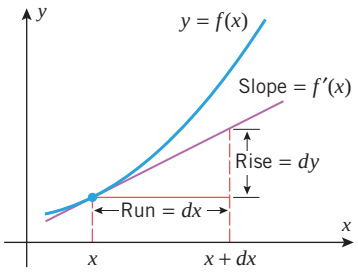
Newton and Leibniz each used a different notation when they published their discoveries of calculus, thereby creating a notational divide between Britain and the European continent that lasted for more than 50 years. The ***Leibniz notation*** $dy/dx$ eventually prevailed because it suggests correct formulas in a natural way, the chain rule

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$$

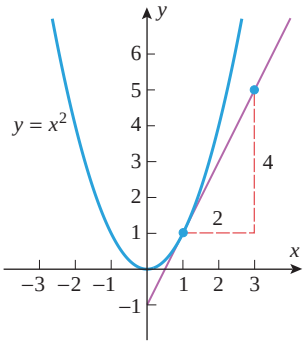
being a good example.

Up to now we have interpreted $dy/dx$ as a single entity representing the derivative of $y$ with respect to $x$; the symbols "$dy$" and "$dx$," which are called ***differentials***, have had no meanings attached to them. Our next goal is to define these symbols in such a way that $dy/dx$ can be treated as an actual ratio. To do this, assume that $f$ is differentiable at a point $x$, *define* $dx$ to be an independent variable that can have any real value, and *define* $dy$ by the formula

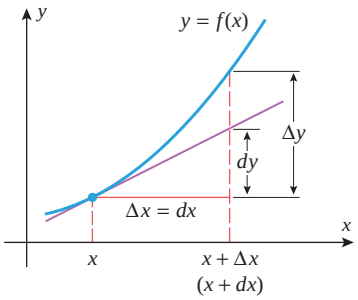
$$dy = f'(x)\,dx \tag{5}$$



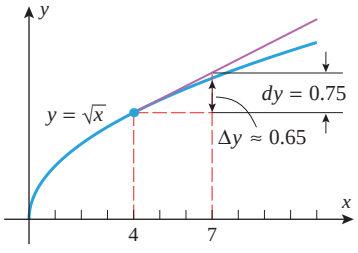
▲ Figure 3.5.5



▲ Figure 3.5.6



▲ Figure 3.5.7



▲ Figure 3.5.8

If $dx \neq 0$, then we can divide both sides of (5) by $dx$ to obtain

$$\frac{dy}{dx} = f'(x) \tag{6}$$

Thus, we have achieved our goal of defining $dy$ and $dx$ so their ratio is $f'(x)$. Formula (5) is said to express (6) in ***differential form***.

To interpret (5) geometrically, note that $f'(x)$ is the slope of the tangent line to the graph of $f$ at $x$. The differentials $dy$ and $dx$ can be viewed as a corresponding rise and run of this tangent line (Figure 3.5.5).

▶ **Example 3** Express the derivative with respect to $x$ of $y = x^2$ in differential form, and discuss the relationship between $dy$ and $dx$ at $x = 1$.

***Solution.*** The derivative of $y$ with respect to $x$ is $dy/dx = 2x$, which can be expressed in differential form as

$$dy = 2x\,dx$$

When $x = 1$ this becomes

$$dy = 2\,dx$$

This tells us that if we travel along the tangent line to the curve $y = x^2$ at $x = 1$, then a change of $dx$ units in $x$ produces a change of $2\,dx$ units in $y$. Thus, for example, a run of $dx = 2$ units produces a rise of $dy = 4$ units along the tangent line (Figure 3.5.6). ◀

It is important to understand the distinction between the increment $\Delta y$ and the differential $dy$. To see the difference, let us assign the independent variables $dx$ and $\Delta x$ the same value, so $dx = \Delta x$. Then $\Delta y$ represents the change in $y$ that occurs when we start at $x$ and travel *along the curve* $y = f(x)$ until we have moved $\Delta x\ (= dx)$ units in the $x$-direction, while $dy$ represents the change in $y$ that occurs if we start at $x$ and travel *along the tangent line* until we have moved $dx\ (= \Delta x)$ units in the $x$-direction (Figure 3.5.7).

▶ **Example 4** Let $y = \sqrt{x}$.

(a) Find formulas for $\Delta y$ and $dy$.

(b) Evaluate $\Delta y$ and $dy$ at $x = 4$ with $dx = \Delta x = 3$. Then make a sketch of $y = \sqrt{x}$, showing the values of $\Delta y$ and $dy$ in the picture.

***Solution (a).*** With $y = f(x) = \sqrt{x}$ we obtain

$$\Delta y = f(x + \Delta x) - f(x) = \sqrt{x + \Delta x} - \sqrt{x}$$

and

$$\frac{dy}{dx} = \frac{1}{2\sqrt{x}}, \quad \text{so} \quad dy = \frac{1}{2\sqrt{x}}\,dx$$

***Solution (b).*** At $x = 4$ with $dx = \Delta x = 3$,

$$\Delta y = \sqrt{7} - \sqrt{4} \approx 0.65$$

and

$$dy = \frac{1}{2\sqrt{4}}(3) = \frac{3}{4} = 0.75$$

Figure 3.5.8 shows the curve $y = \sqrt{x}$ together with $\Delta y$ and $dy$. ◀

## LOCAL LINEAR APPROXIMATION FROM THE DIFFERENTIAL POINT OF VIEW

Although $\Delta y$ and $dy$ are generally different, the differential $dy$ will nonetheless be a good approximation of $\Delta y$ provided $dx = \Delta x$ is close to 0. To see this, recall from Section 2.2 that

$$f'(x) = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}$$

It follows that if $\Delta x$ is close to 0, then we will have $f'(x) \approx \Delta y/\Delta x$ or, equivalently,

$$\Delta y \approx f'(x)\Delta x$$

If we agree to let $dx = \Delta x$, then we can rewrite this as

$$\Delta y \approx f'(x)\,dx = dy \tag{7}$$

In words, this states that for values of $dx$ near zero the differential $dy$ closely approximates the increment $\Delta y$ (Figure 3.5.7). But this is to be expected since the graph of the tangent line at $x$ is the local linear approximation of the graph of $f$.

## ERROR PROPAGATION

© Michael Newman/PhotoEdit

*Real-world measurements inevitably have small errors.*

In real-world applications, small errors in measured quantities will invariably occur. These measurement errors are of importance in scientific research—all scientific measurements come with measurement errors included. For example, your height might be measured as $170 \pm 0.5$ cm, meaning that your exact height lies somewhere between 169.5 and 170.5 cm. Researchers often must use these inexactly measured quantities to compute other quantities, thereby *propagating* the errors from the measured quantitites to the computed quantities. This phenomenon is called ***error propagation***. Researchers must be able to estimate errors in the computed quantities. Our goal is to show how to estimate these errors using local linear approximation and differentials. For this purpose, suppose

$x_0$ is the exact value of the quantity being measured
$y_0 = f(x_0)$ is the exact value of the quantity being computed
$x$ is the measured value of $x_0$
$y = f(x)$ is the computed value of $y$

We define

$dx\ (= \Delta x) = x - x_0$ to be the ***measurement error*** of $x$
$\Delta y = f(x) - f(x_0)$ to be the ***propagated error*** of $y$

It follows from (7) with $x_0$ replacing $x$ that the propagated error $\Delta y$ can be approximated by

$$\Delta y \approx dy = f'(x_0)\,dx \tag{8}$$

Unfortunately, there is a practical difficulty in applying this formula since the value of $x_0$ is unknown. (Keep in mind that only the measured value $x$ is known to the researcher.) This being the case, it is standard practice in research to use the measured value $x$ in place of $x_0$ in (8) and use the approximation

$$\Delta y \approx dy = f'(x)\,dx \tag{9}$$

for the propagated error.

Note that measurement error is positive if the measured value is greater than the exact value and is negative if it is less than the exact value. The sign of the propagated error conveys similar information.

Explain why an error estimate of at most $\pm\frac{1}{32}$ inch is reasonable for a ruler that is calibrated in sixteenths of an inch.

▶ **Example 5** Suppose that the side of a square is measured with a ruler to be 10 inches with a measurement error of at most $\pm\frac{1}{32}$ in. Estimate the error in the computed area of the square.

***Solution.*** Let $x$ denote the exact length of a side and $y$ the exact area so that $y = x^2$. It follows from (9) with $f(x) = x^2$ that if $dx$ is the measurement error, then the propagated error $\Delta y$ can be approximated as

$$\Delta y \approx dy = 2x\,dx$$

Substituting the measured value $x = 10$ into this equation yields

$$dy = 20\,dx \tag{10}$$

But to say that the measurement error is at most $\pm\frac{1}{32}$ means that

$$-\frac{1}{32} \le dx \le \frac{1}{32}$$

Multiplying these inequalities through by 20 and applying (10) yields

$$20\left(-\tfrac{1}{32}\right) \le dy \le 20\left(\tfrac{1}{32}\right) \quad \text{or equivalently} \quad -\tfrac{5}{8} \le dy \le \tfrac{5}{8}$$

Thus, the propagated error in the area is estimated to be within $\pm\frac{5}{8}$ in$^2$. ◀

If the true value of a quantity is $q$ and a measurement or calculation produces an error $\Delta q$, then $\Delta q/q$ is called the ***relative error*** in the measurement or calculation; when expressed as a percentage, $\Delta q/q$ is called the ***percentage error***. As a practical matter, the true value $q$ is usually unknown, so that the measured or calculated value of $q$ is used instead; and the relative error is approximated by $dq/q$.

▶ **Example 6** The diameter of a polyurethane sphere is measured with percentage error within $\pm 0.4\%$. Estimate the percentage error in the calculated volume of the sphere.

***Solution.*** A sphere of diameter $x$ has radius $r = x/2$ and volume

$$V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi\left(\frac{x}{2}\right)^3 = \frac{1}{6}\pi x^3$$

Therefore

$$\frac{dV}{dx} = \frac{1}{2}\pi x^2 \quad \text{and} \quad dV = \frac{1}{2}\pi x^2\,dx$$

The relative error in $V$ is then approximately

$$\frac{dV}{V} = \frac{\frac{1}{2}\pi x^2\,dx}{\frac{1}{6}\pi x^3} = 3\,\frac{dx}{x} \tag{11}$$

We are given that the percentage error in the measured value of $x$ is within $\pm 0.4\%$, which means that

$$-0.004 \le \frac{dx}{x} \le 0.004$$

Multiplying these inequalities through by 3 and applying (11) yields

$$-0.012 \le \frac{dV}{V} \le 0.012$$

Thus, we estimate the percentage error in the calculated value of $V$ to be within $\pm 1.2\%$. ◀

## MORE NOTATION; DIFFERENTIAL FORMULAS

The symbol $df$ is another common notation for the differential of a function $y = f(x)$. For example, if $f(x) = \sin x$, then we can write $df = \cos x\,dx$. We can also view the symbol "$d$" as an *operator* that acts on a function to produce the corresponding differential. For example, $d[x^2] = 2x\,dx$, $d[\sin x] = \cos x\,dx$, and so on. All of the general rules of differentiation then have corresponding differential versions:

| DERIVATIVE FORMULA | DIFFERENTIAL FORMULA |
|---|---|
| $\frac{d}{dx}[c] = 0$ | $d[c] = 0$ |
| $\frac{d}{dx}[cf] = c\frac{df}{dx}$ | $d[cf] = c\,df$ |
| $\frac{d}{dx}[f+g] = \frac{df}{dx} + \frac{dg}{dx}$ | $d[f+g] = df + dg$ |
| $\frac{d}{dx}[fg] = f\frac{dg}{dx} + g\frac{df}{dx}$ | $d[fg] = f\,dg + g\,df$ |
| $\frac{d}{dx}\left[\frac{f}{g}\right] = \frac{g\frac{df}{dx} - f\frac{dg}{dx}}{g^2}$ | $d\left[\frac{f}{g}\right] = \frac{g\,df - f\,dg}{g^2}$ |

For example,

$$\begin{aligned} d[x^2 \sin x] &= (x^2 \cos x + 2x \sin x)\, dx \\ &= x^2(\cos x\, dx) + (2x\, dx) \sin x \\ &= x^2 d[\sin x] + (\sin x)\, d[x^2] \end{aligned}$$

illustrates the differential version of the product rule.

## ✔ QUICK CHECK EXERCISES 3.5 (See page 219 for answers.)

1. The local linear approximation of $f$ at $x_0$ uses the _____ line to the graph of $y = f(x)$ at $x = x_0$ to approximate values of _____ for values of $x$ near _____.
2. Find an equation for the local linear approximation to $y = 5 - x^2$ at $x_0 = 2$.
3. Let $y = 5 - x^2$. Find $dy$ and $\Delta y$ at $x = 2$ with $dx = \Delta x = 0.1$.
4. The intensity of light from a light source is a function $I = f(x)$ of the distance $x$ from the light source. Suppose that a small gemstone is measured to be 10 m from a light source, $f(10) = 0.2\ \text{W/m}^2$, and $f'(10) = -0.04\ \text{W/m}^3$. If the distance $x = 10$ m was obtained with a measurement error within $\pm 0.05$ m, estimate the percentage error in the calculated intensity of the light on the gemstone.

## EXERCISE SET 3.5 Graphing Utility

1. (a) Use Formula (1) to obtain the local linear approximation of $x^3$ at $x_0 = 1$.
   (b) Use Formula (2) to rewrite the approximation obtained in part (a) in terms of $\Delta x$.
   (c) Use the result obtained in part (a) to approximate $(1.02)^3$, and confirm that the formula obtained in part (b) produces the same result.
2. (a) Use Formula (1) to obtain the local linear approximation of $1/x$ at $x_0 = 2$.
   (b) Use Formula (2) to rewrite the approximation obtained in part (a) in terms of $\Delta x$.
   (c) Use the result obtained in part (a) to approximate $1/2.05$, and confirm that the formula obtained in part (b) produces the same result.

### FOCUS ON CONCEPTS

3. (a) Find the local linear approximation of the function $f(x) = \sqrt{1+x}$ at $x_0 = 0$, and use it to approximate $\sqrt{0.9}$ and $\sqrt{1.1}$.
   (b) Graph $f$ and its tangent line at $x_0$ together, and use the graphs to illustrate the relationship between the exact values and the approximations of $\sqrt{0.9}$ and $\sqrt{1.1}$.
4. A student claims that whenever a local linear approximation is used to approximate the square root of a number, the approximation is too large.
   (a) Write a few sentences that make the student's claim precise, and justify this claim geometrically.
   (b) Verify the student's claim algebraically using approximation (1).

**5–10** Confirm that the stated formula is the local linear approximation at $x_0 = 0$. ■

5. $(1+x)^{15} \approx 1 + 15x$
6. $\dfrac{1}{\sqrt{1-x}} \approx 1 + \dfrac{1}{2}x$
7. $\tan x \approx x$
8. $\dfrac{1}{1+x} \approx 1 - x$
9. $e^x \approx 1 + x$
10. $\ln(1+x) \approx x$

**11–16** Confirm that the stated formula is the local linear approximation of $f$ at $x_0 = 1$, where $\Delta x = x - 1$. ■

11. $f(x) = x^4;\ (1+\Delta x)^4 \approx 1 + 4\Delta x$
12. $f(x) = \sqrt{x};\ \sqrt{1+\Delta x} \approx 1 + \frac{1}{2}\Delta x$
13. $f(x) = \dfrac{1}{2+x};\ \dfrac{1}{3+\Delta x} \approx \dfrac{1}{3} - \dfrac{1}{9}\Delta x$
14. $f(x) = (4+x)^3;\ (5+\Delta x)^3 \approx 125 + 75\Delta x$
15. $\tan^{-1} x;\ \tan^{-1}(1+\Delta x) \approx \dfrac{\pi}{4} + \dfrac{1}{2}\Delta x$
16. $\sin^{-1}\left(\dfrac{x}{2}\right);\ \sin^{-1}\left(\dfrac{1}{2} + \dfrac{1}{2}\Delta x\right) \approx \dfrac{\pi}{6} + \dfrac{1}{\sqrt{3}}\Delta x$

**17–20** Confirm that the formula is the local linear approximation at $x_0 = 0$, and use a graphing utility to estimate an interval of $x$-values on which the error is at most $\pm 0.1$. ■

17. $\sqrt{x+3} \approx \sqrt{3} + \dfrac{1}{2\sqrt{3}}x$
18. $\dfrac{1}{\sqrt{9-x}} \approx \dfrac{1}{3} + \dfrac{1}{54}x$
19. $\tan 2x \approx 2x$
20. $\dfrac{1}{(1+2x)^5} \approx 1 - 10x$

21. (a) Use the local linear approximation of $\sin x$ at $x_0 = 0$ obtained in Example 2 to approximate $\sin 1°$, and compare the approximation to the result produced directly by your calculating device.
    (b) How would you choose $x_0$ to approximate $\sin 44°$?
    (c) Approximate $\sin 44°$; compare the approximation to the result produced directly by your calculating device.
22. (a) Use the local linear approximation of $\tan x$ at $x_0 = 0$ to approximate $\tan 2°$, and compare the approximation to the result produced directly by your calculating device.
    (b) How would you choose $x_0$ to approximate $\tan 61°$?

(cont.)

(c) Approximate $\tan 61°$; compare the approximation to the result produced directly by your calculating device.

**23–33** Use an appropriate local linear approximation to estimate the value of the given quantity. ■

**23.** $(3.02)^4$ **24.** $(1.97)^3$ **25.** $\sqrt{65}$

**26.** $\sqrt{24}$ **27.** $\sqrt{80.9}$ **28.** $\sqrt{36.03}$

**29.** $\sin 0.1$ **30.** $\tan 0.2$ **31.** $\cos 31°$

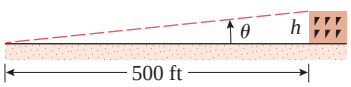
**32.** $\ln(1.01)$ **33.** $\tan^{-1}(0.99)$

**FOCUS ON CONCEPTS**

**34.** The approximation $(1+x)^k \approx 1+kx$ is commonly used by engineers for quick calculations.
(a) Derive this result, and use it to make a rough estimate of $(1.001)^{37}$.
(b) Compare your estimate to that produced directly by your calculating device.
(c) If $k$ is a positive integer, how is the approximation $(1+x)^k \approx 1+kx$ related to the expansion of $(1+x)^k$ using the binomial theorem?

**35.** Use the approximation $(1+x)^k \approx 1+kx$, along with some mental arithmetic to show that $\sqrt[3]{8.24} \approx 2.02$ and $4.08^{3/2} \approx 8.24$.

**36.** Referring to the accompanying figure, suppose that the angle of elevation of the top of the building, as measured from a point 500 ft from its base, is found to be $\theta = 6°$. Use an appropriate local linear approximation, along with some mental arithmetic to show that the building is about 52 ft high.



◀ **Figure Ex-36**

**37.** (a) Let $y = 1/x$. Find $dy$ and $\Delta y$ at $x = 1$ with $dx = \Delta x = -0.5$.
(b) Sketch the graph of $y = 1/x$, showing $dy$ and $\Delta y$ in the picture.

**38.** (a) Let $y = \sqrt{x}$. Find $dy$ and $\Delta y$ at $x = 9$ with $dx = \Delta x = -1$.
(b) Sketch the graph of $y = \sqrt{x}$, showing $dy$ and $\Delta y$ in the picture.

**39–42** Find formulas for $dy$ and $\Delta y$. ■

**43–46** Find the differential $dy$. ■

**43.** (a) $y = 4x^3 - 7x^2$ (b) $y = x \cos x$

**44.** (a) $y = 1/x$ (b) $y = 5 \tan x$

**45.** (a) $y = x\sqrt{1-x}$ (b) $y = (1+x)^{-17}$

**46.** (a) $y = \dfrac{1}{x^3 - 1}$ (b) $y = \dfrac{1 - x^3}{2 - x}$

**47–50 True–False** Determine whether the statement is true or false. Explain your answer. ■

**47.** A differential $dy$ is defined to be a very small change in $y$.

**48.** The error in approximation (2) is the same as the error in approximation (7).

**49.** A local linear approximation to a function can never be identically equal to the function.

**50.** A local linear approximation to a nonconstant function can never be constant.

**51–54** Use the differential $dy$ to approximate $\Delta y$ when $x$ changes as indicated. ■

**51.** $y = \sqrt{3x - 2}$; from $x = 2$ to $x = 2.03$

**52.** $y = \sqrt{x^2 + 8}$; from $x = 1$ to $x = 0.97$

**53.** $y = \dfrac{x}{x^2 + 1}$; from $x = 2$ to $x = 1.96$

**54.** $y = x\sqrt{8x + 1}$; from $x = 3$ to $x = 3.05$

**55.** The side of a square is measured to be 10 ft, with a possible error of $\pm 0.1$ ft.
(a) Use differentials to estimate the error in the calculated area.
(b) Estimate the percentage errors in the side and the area.

**56.** The side of a cube is measured to be 25 cm, with a possible error of $\pm 1$ cm.
(a) Use differentials to estimate the error in the calculated volume.
(b) Estimate the percentage errors in the side and volume.

**57.** The hypotenuse of a right triangle is known to be 10 in exactly, and one of the acute angles is measured to be $30°$, with a possible error of $\pm 1°$.
(a) Use differentials to estimate the errors in the sides opposite and adjacent to the measured angle.
(b) Estimate the percentage errors in the sides.

**58.** One side of a right triangle is known to be 25 cm exactly. The angle opposite to this side is measured to be $60°$, with a possible error of $\pm 0.5°$.
(a) Use differentials to estimate the errors in the adjacent side and the hypotenuse.
(b) Estimate the percentage errors in the adjacent side and hypotenuse.

**59.** The electrical resistance $R$ of a certain wire is given by $R = k/r^2$, where $k$ is a constant and $r$ is the radius of the wire. Assuming that the radius $r$ has a possible error of $\pm 5\%$, use differentials to estimate the percentage error in $R$. (Assume $k$ is exact.)

**60.** A 12-foot ladder leaning against a wall makes an angle $\theta$ with the floor. If the top of the ladder is $h$ feet up the wall, express $h$ in terms of $\theta$ and then use $dh$ to estimate the change in $h$ if $\theta$ changes from $60°$ to $59°$.

**61.** The area of a right triangle with a hypotenuse of $H$ is calculated using the formula $A = \frac{1}{4}H^2 \sin 2\theta$, where $\theta$ is one of the acute angles. Use differentials to approximate the error in calculating $A$ if $H = 4$ cm (exactly) and $\theta$ is measured to be $30°$, with a possible error of $\pm 15'$.

**62.** The side of a square is measured with a possible percentage error of $\pm 1\%$. Use differentials to estimate the percentage error in the area.

**63.** The side of a cube is measured with a possible percentage error of $\pm 2\%$. Use differentials to estimate the percentage error in the volume.

**64.** The volume of a sphere is to be computed from a measured value of its radius. Estimate the maximum permissible percentage error in the measurement if the percentage error in the volume must be kept within $\pm 3\%$. ($V = \frac{4}{3}\pi r^3$ is the volume of a sphere of radius $r$.)

**65.** The area of a circle is to be computed from a measured value of its diameter. Estimate the maximum permissible percentage error in the measurement if the percentage error in the area must be kept within $\pm 1\%$.

**66.** A steel cube with 1-inch sides is coated with 0.01 inch of copper. Use differentials to estimate the volume of copper in the coating. [*Hint:* Let $\Delta V$ be the change in the volume of the cube.]

**67.** A metal rod 15 cm long and 5 cm in diameter is to be covered (except for the ends) with insulation that is 0.1 cm thick. Use differentials to estimate the volume of insulation. [*Hint:* Let $\Delta V$ be the change in volume of the rod.]

**68.** The time required for one complete oscillation of a pendulum is called its ***period***. If $L$ is the length of the pendulum and the oscillation is small, then the period is given by $P = 2\pi\sqrt{L/g}$, where $g$ is the constant acceleration due to gravity. Use differentials to show that the percentage error in $P$ is approximately half the percentage error in $L$.

**69.** If the temperature $T$ of a metal rod of length $L$ is changed by an amount $\Delta T$, then the length will change by the amount $\Delta L = \alpha L \Delta T$, where $\alpha$ is called the ***coefficient of linear expansion***. For moderate changes in temperature $\alpha$ is taken as constant.

(a) Suppose that a rod 40 cm long at 20°C is found to be 40.006 cm long when the temperature is raised to 30°C. Find $\alpha$.

(b) If an aluminum pole is 180 cm long at 15°C, how long is the pole if the temperature is raised to 40°C? [Take $\alpha = 2.3 \times 10^{-5}/^\circ\text{C}$.]

**70.** If the temperature $T$ of a solid or liquid of volume $V$ is changed by an amount $\Delta T$, then the volume will change by the amount $\Delta V = \beta V \Delta T$, where $\beta$ is called the ***coefficient of volume expansion***. For moderate changes in temperature $\beta$ is taken as constant. Suppose that a tank truck loads 4000 gallons of ethyl alcohol at a temperature of 35°C and delivers its load sometime later at a temperature of 15°C. Using $\beta = 7.5 \times 10^{-4}/^\circ\text{C}$ for ethyl alcohol, find the number of gallons delivered.

**71.** **Writing** Explain why the local linear approximation of a function value is equivalent to the use of a differential to approximate a change in the function.

**72.** **Writing** The local linear approximation

$$\sin x \approx x$$

is known as the *small angle approximation* and has both practical and theoretical applications. Do some research on some of these applications, and write a short report on the results of your investigations.

# 3.6 L'HÔPITAL'S RULE; INDETERMINATE FORMS

*In this section we will discuss a general method for using derivatives to find limits. This method will enable us to establish limits with certainty that earlier in the text we were only able to conjecture using numerical or graphical evidence. The method that we will discuss in this section is an extremely powerful tool that is used internally by many computer programs to calculate limits of various types.*

## INDETERMINATE FORMS OF TYPE 0/0

Recall that a limit of the form

$$\lim_{x \to a} \frac{f(x)}{g(x)} \tag{1}$$

in which $f(x) \to 0$ and $g(x) \to 0$ as $x \to a$ is called an ***indeterminate form of type*** $\mathbf{0/0}$. Some examples encountered earlier in the text are

$$\lim_{x \to 1} \frac{x^2 - 1}{x - 1} = 2, \quad \lim_{x \to 0} \frac{\sin x}{x} = 1, \quad \lim_{x \to 0} \frac{1 - \cos x}{x} = 0$$

The first limit was obtained algebraically by factoring the numerator and canceling the common factor of $x - 1$, and the second two limits were obtained using geometric methods. However, there are many indeterminate forms for which neither algebraic nor geometric methods will produce the limit, so we need to develop a more general method.

To motivate such a method, suppose that (1) is an indeterminate form of type $0/0$ in which $f'$ and $g'$ are continuous at $x = a$ and $g'(a) \neq 0$. Since $f$ and $g$ can be closely approximated by their local linear approximations near $a$, it is reasonable to expect that

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \lim_{x \to a} \frac{f(a) + f'(a)(x - a)}{g(a) + g'(a)(x - a)} \tag{2}$$

Since we are assuming that $f'$ and $g'$ are continuous at $x = a$, we have

$$\lim_{x \to a} f'(x) = f'(a) \quad \text{and} \quad \lim_{x \to a} g'(x) = g'(a)$$

and since the differentiability of $f$ and $g$ at $x = a$ implies the continuity of $f$ and $g$ at $x = a$, we have

$$f(a) = \lim_{x \to a} f(x) = 0 \quad \text{and} \quad g(a) = \lim_{x \to a} g(x) = 0$$

Thus, we can rewrite (2) as

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \lim_{x \to a} \frac{f'(a)(x - a)}{g'(a)(x - a)} = \lim_{x \to a} \frac{f'(a)}{g'(a)} = \lim_{x \to a} \frac{f'(x)}{g'(x)} \tag{3}$$

This result, called ***L'Hôpital's rule***, converts the given indeterminate form into a limit involving derivatives that is often easier to evaluate.

Although we motivated (3) by assuming that $f$ and $g$ have continuous derivatives at $x = a$ and that $g'(a) \neq 0$, the result is true under less stringent conditions and is also valid for one-sided limits and limits at $+\infty$ and $-\infty$. The proof of the following precise statement of L'Hôpital's rule is omitted.

**3.6.1 THEOREM (*L'Hôpital's Rule for Form 0/0*)** *Suppose that $f$ and $g$ are differentiable functions on an open interval containing $x = a$, except possibly at $x = a$, and that*

$$\lim_{x \to a} f(x) = 0 \quad \textit{and} \quad \lim_{x \to a} g(x) = 0$$

*If $\lim_{x \to a} [f'(x)/g'(x)]$ exists, or if this limit is $+\infty$ or $-\infty$, then*

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \lim_{x \to a} \frac{f'(x)}{g'(x)}$$

*Moreover, this statement is also true in the case of a limit as $x \to a^-$, $x \to a^+$, $x \to -\infty$, or as $x \to +\infty$.*

**WARNING**

Note that in L'Hôpital's rule the numerator and denominator are differentiated individually. This is *not* the same as differentiating $f(x)/g(x)$.

In the examples that follow we will apply L'Hôpital's rule using the following three-step process:

***Applying L'Hôpital's Rule***

**Step 1.** Check that the limit of $f(x)/g(x)$ is an indeterminate form of type $0/0$.

**Step 2.** Differentiate $f$ and $g$ separately.

**Step 3.** Find the limit of $f'(x)/g'(x)$. If this limit is finite, $+\infty$, or $-\infty$, then it is equal to the limit of $f(x)/g(x)$.

▶ **Example 1** Find the limit

$$\lim_{x\to 2}\frac{x^2-4}{x-2}$$

using L'Hôpital's rule, and check the result by factoring.

***Solution.*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type 0/0. Applying L'Hôpital's rule yields

$$\lim_{x\to 2}\frac{x^2-4}{x-2}=\lim_{x\to 2}\frac{\dfrac{d}{dx}[x^2-4]}{\dfrac{d}{dx}[x-2]}=\lim_{x\to 2}\frac{2x}{1}=4$$

This agrees with the computation

$$\lim_{x\to 2}\frac{x^2-4}{x-2}=\lim_{x\to 2}\frac{(x-2)(x+2)}{x-2}=\lim_{x\to 2}(x+2)=4 \quad \blacktriangleleft$$

The limit in Example 1 can be interpreted as the limit form of a certain derivative. Use that derivative to evaluate the limit.

▶ **Example 2** In each part confirm that the limit is an indeterminate form of type 0/0, and evaluate it using L'Hôpital's rule.

(a) $\displaystyle\lim_{x\to 0}\frac{\sin 2x}{x}$ (b) $\displaystyle\lim_{x\to \pi/2}\frac{1-\sin x}{\cos x}$ (c) $\displaystyle\lim_{x\to 0}\frac{e^x-1}{x^3}$

(d) $\displaystyle\lim_{x\to 0^-}\frac{\tan x}{x^2}$ (e) $\displaystyle\lim_{x\to 0}\frac{1-\cos x}{x^2}$ (f) $\displaystyle\lim_{x\to +\infty}\frac{x^{-4/3}}{\sin(1/x)}$

***Solution (a).*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type 0/0. Applying L'Hôpital's rule yields

$$\lim_{x\to 0}\frac{\sin 2x}{x}=\lim_{x\to 0}\frac{\dfrac{d}{dx}[\sin 2x]}{\dfrac{d}{dx}[x]}=\lim_{x\to 0}\frac{2\cos 2x}{1}=2$$

Observe that this result agrees with that obtained by substitution in Example 4(b) of Section 1.6.

***Solution (b).*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type 0/0. Applying L'Hôpital's rule yields

$$\lim_{x\to \pi/2}\frac{1-\sin x}{\cos x}=\lim_{x\to \pi/2}\frac{\dfrac{d}{dx}[1-\sin x]}{\dfrac{d}{dx}[\cos x]}=\lim_{x\to \pi/2}\frac{-\cos x}{-\sin x}=\frac{0}{-1}=0$$

**WARNING**

Applying L'Hôpital's rule to limits that are not indeterminate forms can produce incorrect results. For example, the computation

$$\lim_{x\to 0}\frac{x+6}{x+2}=\lim_{x\to 0}\frac{\dfrac{d}{dx}[x+6]}{\dfrac{d}{dx}[x+2]}=\lim_{x\to 0}\frac{1}{1}=1$$

is ***not valid***, since the limit is not an indeterminate form. The correct result is

$$\lim_{x\to 0}\frac{x+6}{x+2}=\frac{0+6}{0+2}=3$$

**Guillaume François Antoine de L'Hôpital (1661–1704)** French mathematician. L'Hôpital, born to parents of the French high nobility, held the title of Marquis de Sainte-Mesme Comte d'Autrement. He showed mathematical talent quite early and at age 15 solved a difficult problem about cycloids posed by Pascal. As a young man he served briefly as a cavalry officer, but resigned because of nearsightedness. In his own time he gained fame as the author of the first textbook ever published on differential calculus, *L'Analyse des Infiniment Petits pour l'Intelligence des Lignes Courbes* (1696). L'Hôpital's rule appeared for the first time in that book. Actually, L'Hôpital's rule and most of the material in the calculus text were due to John Bernoulli, who was L'Hôpital's teacher. L'Hôpital dropped his plans for a book on integral calculus when Leibniz informed him that he intended to write such a text. L'Hôpital was apparently generous and personable, and his many contacts with major mathematicians provided the vehicle for disseminating major discoveries in calculus throughout Europe.

[*Image: http://en.wikipedia.org/wiki/File:Guillaume_de_l%27H%C3%B4pital.jpg*]

***Solution (c).*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type $0/0$. Applying L'Hôpital's rule yields

$$\lim_{x\to 0}\frac{e^x-1}{x^3}=\lim_{x\to 0}\frac{\dfrac{d}{dx}[e^x-1]}{\dfrac{d}{dx}[x^3]}=\lim_{x\to 0}\frac{e^x}{3x^2}=+\infty$$

***Solution (d).*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type $0/0$. Applying L'Hôpital's rule yields

$$\lim_{x\to 0^-}\frac{\tan x}{x^2}=\lim_{x\to 0^-}\frac{\sec^2 x}{2x}=-\infty$$

***Solution (e).*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type $0/0$. Applying L'Hôpital's rule yields

$$\lim_{x\to 0}\frac{1-\cos x}{x^2}=\lim_{x\to 0}\frac{\sin x}{2x}$$

Since the new limit is another indeterminate form of type $0/0$, we apply L'Hôpital's rule again:

$$\lim_{x\to 0}\frac{1-\cos x}{x^2}=\lim_{x\to 0}\frac{\sin x}{2x}=\lim_{x\to 0}\frac{\cos x}{2}=\frac{1}{2}$$

***Solution (f).*** The numerator and denominator have a limit of 0, so the limit is an indeterminate form of type $0/0$. Applying L'Hôpital's rule yields

$$\lim_{x\to +\infty}\frac{x^{-4/3}}{\sin(1/x)}=\lim_{x\to +\infty}\frac{-\frac{4}{3}x^{-7/3}}{(-1/x^2)\cos(1/x)}=\lim_{x\to +\infty}\frac{\frac{4}{3}x^{-1/3}}{\cos(1/x)}=\frac{0}{1}=0 \quad \blacktriangleleft$$

## INDETERMINATE FORMS OF TYPE $\infty/\infty$

When we want to indicate that the limit (or a one-sided limit) of a function is $+\infty$ or $-\infty$ without being specific about the sign, we will say that the limit is $\infty$. For example,

$$\lim_{x\to a^+}f(x)=\infty \quad \text{means} \quad \lim_{x\to a^+}f(x)=+\infty \quad \text{or} \quad \lim_{x\to a^+}f(x)=-\infty$$

$$\lim_{x\to +\infty}f(x)=\infty \quad \text{means} \quad \lim_{x\to +\infty}f(x)=+\infty \quad \text{or} \quad \lim_{x\to +\infty}f(x)=-\infty$$

$$\lim_{x\to a}f(x)=\infty \quad \text{means} \quad \lim_{x\to a^+}f(x)=\pm\infty \quad \text{and} \quad \lim_{x\to a^-}f(x)=\pm\infty$$

The limit of a ratio, $f(x)/g(x)$, in which the numerator has limit $\infty$ and the denominator has limit $\infty$ is called an ***indeterminate form of type*** $\infty/\infty$. The following version of L'Hôpital's rule, which we state without proof, can often be used to evaluate limits of this type.

**3.6.2 THEOREM (*L'Hôpital's Rule for Form* $\infty/\infty$)** *Suppose that $f$ and $g$ are differentiable functions on an open interval containing $x=a$, except possibly at $x=a$, and that*

$$\lim_{x\to a}f(x)=\infty \quad \textit{and} \quad \lim_{x\to a}g(x)=\infty$$

*If $\lim_{x\to a}[f'(x)/g'(x)]$ exists, or if this limit is $+\infty$ or $-\infty$, then*

$$\lim_{x\to a}\frac{f(x)}{g(x)}=\lim_{x\to a}\frac{f'(x)}{g'(x)}$$

*Moreover, this statement is also true in the case of a limit as $x\to a^-$, $x\to a^+$, $x\to -\infty$, or as $x\to +\infty$.*

**Example 3** In each part confirm that the limit is an indeterminate form of type $\infty/\infty$ and apply L'Hôpital's rule.

$$\text{(a)}\ \lim_{x\to+\infty}\frac{x}{e^x} \qquad \text{(b)}\ \lim_{x\to 0^+}\frac{\ln x}{\csc x}$$

***Solution (a).*** The numerator and denominator both have a limit of $+\infty$, so we have an indeterminate form of type $\infty/\infty$. Applying L'Hôpital's rule yields

$$\lim_{x\to+\infty}\frac{x}{e^x}=\lim_{x\to+\infty}\frac{1}{e^x}=0$$

***Solution (b).*** The numerator has a limit of $-\infty$ and the denominator has a limit of $+\infty$, so we have an indeterminate form of type $\infty/\infty$. Applying L'Hôpital's rule yields

$$\lim_{x\to 0^+}\frac{\ln x}{\csc x}=\lim_{x\to 0^+}\frac{1/x}{-\csc x\cot x} \tag{4}$$

This last limit is again an indeterminate form of type $\infty/\infty$. Moreover, any additional applications of L'Hôpital's rule will yield powers of $1/x$ in the numerator and expressions involving $\csc x$ and $\cot x$ in the denominator; thus, repeated application of L'Hôpital's rule simply produces new indeterminate forms. We must try something else. The last limit in (4) can be rewritten as

$$\lim_{x\to 0^+}\left(-\frac{\sin x}{x}\tan x\right)=-\lim_{x\to 0^+}\frac{\sin x}{x}\cdot\lim_{x\to 0^+}\tan x=-(1)(0)=0$$

Thus,

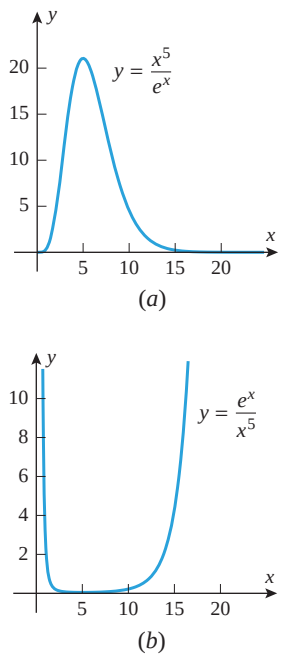
$$\lim_{x\to 0^+}\frac{\ln x}{\csc x}=0 \quad\blacktriangleleft$$

## ANALYZING THE GROWTH OF EXPONENTIAL FUNCTIONS USING L'HÔPITAL'S RULE

If $n$ is any positive integer, then $x^n\to+\infty$ as $x\to+\infty$. Such integer powers of $x$ are sometimes used as "measuring sticks" to describe how rapidly other functions grow. For example, we know that $e^x\to+\infty$ as $x\to+\infty$ and that the growth of $e^x$ is very rapid (Table 0.5.5); however, the growth of $x^n$ is also rapid when $n$ is a high power, so it is reasonable to ask whether high powers of $x$ grow more or less rapidly than $e^x$. One way to investigate this is to examine the behavior of the ratio $x^n/e^x$ as $x\to+\infty$. For example, Figure 3.6.1*a* shows the graph of $y=x^5/e^x$. This graph suggests that $x^5/e^x\to 0$ as $x\to+\infty$, and this implies that the growth of the function $e^x$ is sufficiently rapid that its values eventually overtake those of $x^5$ and force the ratio toward zero. Stated informally, "$e^x$ eventually grows more rapidly than $x^5$." The same conclusion could have been reached by putting $e^x$ on top and examining the behavior of $e^x/x^5$ as $x\to+\infty$ (Figure 3.6.1*b*). In this case the values of $e^x$ eventually overtake those of $x^5$ and force the ratio toward $+\infty$. More generally, we can use L'Hôpital's rule to show that *$e^x$ eventually grows more rapidly than any positive integer power of $x$*, that is,

$$\lim_{x\to+\infty}\frac{x^n}{e^x}=0 \quad\text{and}\quad \lim_{x\to+\infty}\frac{e^x}{x^n}=+\infty \tag{5–6}$$

Both limits are indeterminate forms of type $\infty/\infty$ that can be evaluated using L'Hôpital's rule. For example, to establish (5), we will need to apply L'Hôpital's rule $n$ times. For this purpose, observe that successive differentiations of $x^n$ reduce the exponent by 1 each time, thus producing a constant for the $n$th derivative. For example, the successive derivatives



▲ Figure 3.6.1

of $x^3$ are $3x^2$, $6x$, and 6. In general, the $n$th derivative of $x^n$ is $n(n-1)(n-2)\cdots 1 = n!$ (verify).* Thus, applying L'Hôpital's rule $n$ times to (5) yields

$$\lim_{x\to+\infty}\frac{x^n}{e^x} = \lim_{x\to+\infty}\frac{n!}{e^x} = 0$$

Limit (6) can be established similarly.

## INDETERMINATE FORMS OF TYPE $0\cdot\infty$

Thus far we have discussed indeterminate forms of type $0/0$ and $\infty/\infty$. However, these are not the only possibilities; in general, the limit of an expression that has one of the forms

$$\frac{f(x)}{g(x)}, \quad f(x)\cdot g(x), \quad f(x)^{g(x)}, \quad f(x)-g(x), \quad f(x)+g(x)$$

is called an *indeterminate form* if the limits of $f(x)$ and $g(x)$ individually exert conflicting influences on the limit of the entire expression. For example, the limit

$$\lim_{x\to 0^+} x\ln x$$

is an ***indeterminate form of type*** $\mathbf{0\cdot\infty}$ because the limit of the first factor is 0, the limit of the second factor is $-\infty$, and these two limits exert conflicting influences on the product. On the other hand, the limit

$$\lim_{x\to+\infty}[\sqrt{x}(1-x^2)]$$

is not an indeterminate form because the first factor has a limit of $+\infty$, the second factor has a limit of $-\infty$, and these influences work together to produce a limit of $-\infty$ for the product.

Indeterminate forms of type $0\cdot\infty$ can sometimes be evaluated by rewriting the product as a ratio, and then applying L'Hôpital's rule for indeterminate forms of type $0/0$ or $\infty/\infty$.

**WARNING**

It is tempting to argue that an indeterminate form of type $0\cdot\infty$ has value 0 since "zero times anything is zero." However, this is fallacious since $0\cdot\infty$ is not a product of numbers, but rather a statement about limits. For example, here are two indeterminate forms of type $0\cdot\infty$ whose limits are *not* zero:

$$\lim_{x\to 0}\left(x\cdot\frac{1}{x}\right) = \lim_{x\to 0} 1 = 1$$

$$\lim_{x\to 0^+}\left(\sqrt{x}\cdot\frac{1}{x}\right) = \lim_{x\to 0^+}\left(\frac{1}{\sqrt{x}}\right) = +\infty$$

**Example 4** Evaluate

(a) $\lim_{x\to 0^+} x\ln x$ (b) $\lim_{x\to\pi/4}(1-\tan x)\sec 2x$

***Solution (a).*** The factor $x$ has a limit of 0 and the factor $\ln x$ has a limit of $-\infty$, so the stated problem is an indeterminate form of type $0\cdot\infty$. There are two possible approaches: we can rewrite the limit as

$$\lim_{x\to 0^+}\frac{\ln x}{1/x} \quad \text{or} \quad \lim_{x\to 0^+}\frac{x}{1/\ln x}$$

the first being an indeterminate form of type $\infty/\infty$ and the second an indeterminate form of type $0/0$. However, the first form is the preferred initial choice because the derivative of $1/x$ is less complicated than the derivative of $1/\ln x$. That choice yields

$$\lim_{x\to 0^+} x\ln x = \lim_{x\to 0^+}\frac{\ln x}{1/x} = \lim_{x\to 0^+}\frac{1/x}{-1/x^2} = \lim_{x\to 0^+}(-x) = 0$$

***Solution (b).*** The stated problem is an indeterminate form of type $0\cdot\infty$. We will convert it to an indeterminate form of type $0/0$:

$$\lim_{x\to\pi/4}(1-\tan x)\sec 2x = \lim_{x\to\pi/4}\frac{1-\tan x}{1/\sec 2x} = \lim_{x\to\pi/4}\frac{1-\tan x}{\cos 2x}$$

$$= \lim_{x\to\pi/4}\frac{-\sec^2 x}{-2\sin 2x} = \frac{-2}{-2} = 1 \quad \blacktriangleleft$$

*Recall that for $n \geq 1$ the expression $n!$, read ***n-factorial***, denotes the product of the first $n$ positive integers.

## INDETERMINATE FORMS OF TYPE $\infty - \infty$

A limit problem that leads to one of the expressions

$$(+\infty) - (+\infty), \quad (-\infty) - (-\infty),$$
$$(+\infty) + (-\infty), \quad (-\infty) + (+\infty)$$

is called an ***indeterminate form of type*** $\infty - \infty$. Such limits are indeterminate because the two terms exert conflicting influences on the expression: one pushes it in the positive direction and the other pushes it in the negative direction. However, limit problems that lead to one of the expressions

$$(+\infty) + (+\infty), \quad (+\infty) - (-\infty),$$
$$(-\infty) + (-\infty), \quad (-\infty) - (+\infty)$$

are not indeterminate, since the two terms work together (those on the top produce a limit of $+\infty$ and those on the bottom produce a limit of $-\infty$).

Indeterminate forms of type $\infty - \infty$ can sometimes be evaluated by combining the terms and manipulating the result to produce an indeterminate form of type $0/0$ or $\infty/\infty$.

**▶ Example 5** Evaluate $\lim_{x \to 0^+} \left( \frac{1}{x} - \frac{1}{\sin x} \right)$.

***Solution.*** Both terms have a limit of $+\infty$, so the stated problem is an indeterminate form of type $\infty - \infty$. Combining the two terms yields

$$\lim_{x \to 0^+} \left( \frac{1}{x} - \frac{1}{\sin x} \right) = \lim_{x \to 0^+} \frac{\sin x - x}{x \sin x}$$

which is an indeterminate form of type $0/0$. Applying L'Hôpital's rule twice yields

$$\lim_{x \to 0^+} \frac{\sin x - x}{x \sin x} = \lim_{x \to 0^+} \frac{\cos x - 1}{\sin x + x \cos x}$$
$$= \lim_{x \to 0^+} \frac{-\sin x}{\cos x + \cos x - x \sin x} = \frac{0}{2} = 0 \quad \blacktriangleleft$$

## INDETERMINATE FORMS OF TYPE $0^0$, $\infty^0$, $1^\infty$

Limits of the form

$$\lim f(x)^{g(x)}$$

can give rise to ***indeterminate forms of the types*** $\mathbf{0^0}$, $\boldsymbol{\infty^0}$, ***and*** $\mathbf{1^\infty}$. (The interpretations of these symbols should be clear.) For example, the limit

$$\lim_{x \to 0^+} (1 + x)^{1/x}$$

whose value we know to be $e$ [see Formula (1) of Section 3.2] is an indeterminate form of type $1^\infty$. It is indeterminate because the expressions $1 + x$ and $1/x$ exert two conflicting influences: the first approaches 1, which drives the expression toward 1, and the second approaches $+\infty$, which drives the expression toward $+\infty$.

Indeterminate forms of types $0^0$, $\infty^0$, and $1^\infty$ can sometimes be evaluated by first introducing a dependent variable

$$y = f(x)^{g(x)}$$

and then computing the limit of $\ln y$. Since

$$\ln y = \ln[f(x)^{g(x)}] = g(x) \cdot \ln[f(x)]$$

the limit of $\ln y$ will be an indeterminate form of type $0 \cdot \infty$ (verify), which can be evaluated by methods we have already studied. Once the limit of $\ln y$ is known, it is a straightforward matter to determine the limit of $y = f(x)^{g(x)}$, as we will illustrate in the next example.

**▶ Example 6** Find $\lim_{x\to 0}(1+\sin x)^{1/x}$.

***Solution.*** As discussed above, we begin by introducing a dependent variable

$$y = (1+\sin x)^{1/x}$$

and taking the natural logarithm of both sides:

$$\ln y = \ln(1+\sin x)^{1/x} = \frac{1}{x}\ln(1+\sin x) = \frac{\ln(1+\sin x)}{x}$$

Thus,

$$\lim_{x\to 0}\ln y = \lim_{x\to 0}\frac{\ln(1+\sin x)}{x}$$

which is an indeterminate form of type $0/0$, so by L'Hôpital's rule

$$\lim_{x\to 0}\ln y = \lim_{x\to 0}\frac{\ln(1+\sin x)}{x} = \lim_{x\to 0}\frac{(\cos x)/(1+\sin x)}{1} = 1$$

Since we have shown that $\ln y \to 1$ as $x \to 0$, the continuity of the exponential function implies that $e^{\ln y} \to e^1$ as $x \to 0$, and this implies that $y \to e$ as $x \to 0$. Thus,

$$\lim_{x\to 0}(1+\sin x)^{1/x} = e \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 3.6 (See page 228 for answers.)

**1.** In each part, does L'Hôpital's rule apply to the given limit?

(a) $\lim_{x\to 1}\dfrac{2x-2}{x^3+x-2}$ (b) $\lim_{x\to 0}\dfrac{\cos x}{x}$

(c) $\lim_{x\to 0}\dfrac{e^{2x}-1}{\tan x}$

**2.** Evaluate each of the limits in Quick Check Exercise 1.

**3.** Using L'Hôpital's rule, $\lim_{x\to+\infty}\dfrac{e^x}{500x^2} =$ _____.

## EXERCISE SET 3.6 Graphing Utility C CAS

**1–2** Evaluate the given limit without using L'Hôpital's rule, and then check that your answer is correct using L'Hôpital's rule. ■

**1.** (a) $\lim_{x\to 2}\dfrac{x^2-4}{x^2+2x-8}$ (b) $\lim_{x\to+\infty}\dfrac{2x-5}{3x+7}$

**2.** (a) $\lim_{x\to 0}\dfrac{\sin x}{\tan x}$ (b) $\lim_{x\to 1}\dfrac{x^2-1}{x^3-1}$

**3–6 True–False** Determine whether the statement is true or false. Explain your answer. ■

**3.** L'Hôpital's rule does not apply to $\lim_{x\to-\infty}\dfrac{\ln x}{x}$.

**4.** For any polynomial $p(x)$, $\lim_{x\to+\infty}\dfrac{p(x)}{e^x} = 0$.

**5.** If $n$ is chosen sufficiently large, then $\lim_{x\to+\infty}\dfrac{(\ln x)^n}{x} = +\infty$.

**6.** $\lim_{x\to 0^+}(\sin x)^{1/x} = 0$

**7–45** Find the limits. ■

**7.** $\lim_{x\to 0}\dfrac{e^x-1}{\sin x}$

**8.** $\lim_{x\to 0}\dfrac{\sin 2x}{\sin 5x}$

**9.** $\lim_{\theta\to 0}\dfrac{\tan\theta}{\theta}$

**10.** $\lim_{t\to 0}\dfrac{te^t}{1-e^t}$

**11.** $\lim_{x\to\pi^+}\dfrac{\sin x}{x-\pi}$

**12.** $\lim_{x\to 0^+}\dfrac{\sin x}{x^2}$

**13.** $\lim_{x\to+\infty}\dfrac{\ln x}{x}$

**14.** $\lim_{x\to+\infty}\dfrac{e^{3x}}{x^2}$

**15.** $\lim_{x\to 0^+}\dfrac{\cot x}{\ln x}$

**16.** $\lim_{x\to 0^+}\dfrac{1-\ln x}{e^{1/x}}$

**17.** $\lim_{x\to+\infty}\dfrac{x^{100}}{e^x}$

**18.** $\lim_{x\to 0^+}\dfrac{\ln(\sin x)}{\ln(\tan x)}$

**19.** $\lim_{x\to 0}\dfrac{\sin^{-1}2x}{x}$

**20.** $\lim_{x\to 0}\dfrac{x-\tan^{-1}x}{x^3}$

**21.** $\lim_{x\to+\infty} xe^{-x}$

**22.** $\lim_{x\to\pi^-}(x-\pi)\tan\frac{1}{2}x$

**23.** $\lim_{x\to+\infty} x\sin\dfrac{\pi}{x}$

**24.** $\lim_{x\to 0^+}\tan x\ln x$

**25.** $\lim_{x\to\pi/2^-}\sec 3x\cos 5x$

**26.** $\lim_{x\to\pi}(x-\pi)\cot x$

**27.** $\lim_{x\to+\infty}(1-3/x)^x$

**28.** $\lim_{x\to 0}(1+2x)^{-3/x}$

**29.** $\lim_{x\to 0}(e^x + x)^{1/x}$

**30.** $\lim_{x\to +\infty}(1 + a/x)^{bx}$

**31.** $\lim_{x\to 1}(2 - x)^{\tan[(\pi/2)x]}$

**32.** $\lim_{x\to +\infty}[\cos(2/x)]^{x^2}$

**33.** $\lim_{x\to 0}(\csc x - 1/x)$

**34.** $\lim_{x\to 0}\left(\dfrac{1}{x^2} - \dfrac{\cos 3x}{x^2}\right)$

**35.** $\lim_{x\to +\infty}(\sqrt{x^2 + x} - x)$

**36.** $\lim_{x\to 0}\left(\dfrac{1}{x} - \dfrac{1}{e^x - 1}\right)$

**37.** $\lim_{x\to +\infty}[x - \ln(x^2 + 1)]$

**38.** $\lim_{x\to +\infty}[\ln x - \ln(1 + x)]$

**39.** $\lim_{x\to 0^+} x^{\sin x}$

**40.** $\lim_{x\to 0^+}(e^{2x} - 1)^x$

**41.** $\lim_{x\to 0^+}\left[-\dfrac{1}{\ln x}\right]^x$

**42.** $\lim_{x\to +\infty} x^{1/x}$

**43.** $\lim_{x\to +\infty}(\ln x)^{1/x}$

**44.** $\lim_{x\to 0^+}(-\ln x)^x$

**45.** $\lim_{x\to \pi/2^-}(\tan x)^{(\pi/2)-x}$

**46.** Show that for any positive integer $n$

(a) $\lim_{x\to +\infty}\dfrac{\ln x}{x^n} = 0$ (b) $\lim_{x\to +\infty}\dfrac{x^n}{\ln x} = +\infty$.

**FOCUS ON CONCEPTS**

**47.** (a) Find the error in the following calculation:

$$\lim_{x\to 1}\frac{x^3 - x^2 + x - 1}{x^3 - x^2} = \lim_{x\to 1}\frac{3x^2 - 2x + 1}{3x^2 - 2x} = \lim_{x\to 1}\frac{6x - 2}{6x - 2} = 1$$

(b) Find the correct limit.

**48.** (a) Find the error in the following calculation:

$$\lim_{x\to 2}\frac{e^{3x^2-12x+12}}{x^4 - 16} = \lim_{x\to 2}\frac{(6x - 12)e^{3x^2-12x+12}}{4x^3} = 0$$

(b) Find the correct limit.

**49–52** Make a conjecture about the limit by graphing the function involved with a graphing utility; then check your conjecture using L'Hôpital's rule. ■

**49.** $\lim_{x\to +\infty}\dfrac{\ln(\ln x)}{\sqrt{x}}$

**50.** $\lim_{x\to 0^+} x^x$

**51.** $\lim_{x\to 0^+}(\sin x)^{3/\ln x}$

**52.** $\lim_{x\to (\pi/2)^-}\dfrac{4\tan x}{1 + \sec x}$

**53–56** Make a conjecture about the equations of horizontal asymptotes, if any, by graphing the equation with a graphing utility; then check your answer using L'Hôpital's rule. ■

**53.** $y = \ln x - e^x$

**54.** $y = x - \ln(1 + 2e^x)$

**55.** $y = (\ln x)^{1/x}$

**56.** $y = \left(\dfrac{x + 1}{x + 2}\right)^x$

**57.** Limits of the type

$$0/\infty, \quad \infty/0, \quad 0^\infty, \quad \infty\cdot\infty, \quad +\infty + (+\infty),$$
$$+\infty - (-\infty), \quad -\infty + (-\infty), \quad -\infty - (+\infty)$$

are *not* indeterminate forms. Find the following limits by inspection.

(a) $\lim_{x\to 0^+}\dfrac{x}{\ln x}$ (b) $\lim_{x\to +\infty}\dfrac{x^3}{e^{-x}}$

(c) $\lim_{x\to (\pi/2)^-}(\cos x)^{\tan x}$ (d) $\lim_{x\to 0^+}(\ln x)\cot x$

(e) $\lim_{x\to 0^+}\left(\dfrac{1}{x} - \ln x\right)$ (f) $\lim_{x\to -\infty}(x + x^3)$

**58.** There is a myth that circulates among beginning calculus students which states that all indeterminate forms of types $0^0$, $\infty^0$, and $1^\infty$ have value 1 because "anything to the zero power is 1" and "1 to any power is 1." The fallacy is that $0^0$, $\infty^0$, and $1^\infty$ are not powers of numbers, but rather descriptions of limits. The following examples, which were suggested by Prof. Jack Staib of Drexel University, show that such indeterminate forms can have any positive real value:

(a) $\lim_{x\to 0^+}[x^{(\ln a)/(1+\ln x)}] = a$ (form $0^0$)

(b) $\lim_{x\to +\infty}[x^{(\ln a)/(1+\ln x)}] = a$ (form $\infty^0$)

(c) $\lim_{x\to 0}[(x + 1)^{(\ln a)/x}] = a$ (form $1^\infty$).

Verify these results.

**59–62** Verify that L'Hôpital's rule is of no help in finding the limit; then find the limit, if it exists, by some other method. ■

**59.** $\lim_{x\to +\infty}\dfrac{x + \sin 2x}{x}$

**60.** $\lim_{x\to +\infty}\dfrac{2x - \sin x}{3x + \sin x}$

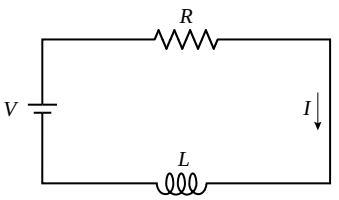
**61.** $\lim_{x\to +\infty}\dfrac{x(2 + \sin 2x)}{x + 1}$

**62.** $\lim_{x\to +\infty}\dfrac{x(2 + \sin x)}{x^2 + 1}$

**63.** The accompanying schematic diagram represents an electrical circuit consisting of an electromotive force that produces a voltage $V$, a resistor with resistance $R$, and an inductor with inductance $L$. It is shown in electrical circuit theory that if the voltage is first applied at time $t = 0$, then the current $I$ flowing through the circuit at time $t$ is given by

$$I = \frac{V}{R}(1 - e^{-Rt/L})$$

What is the effect on the current at a fixed time $t$ if the resistance approaches 0 (i.e., $R \to 0^+$)?



◀ **Figure Ex-63**

**64.** (a) Show that $\lim_{x\to \pi/2}(\pi/2 - x)\tan x = 1$.

(b) Show that

$$\lim_{x\to \pi/2}\left(\frac{1}{\pi/2 - x} - \tan x\right) = 0$$

(c) It follows from part (b) that the approximation

$$\tan x \approx \frac{1}{\pi/2 - x}$$

should be good for values of $x$ near $\pi/2$. Use a calculator to find $\tan x$ and $1/(\pi/2 - x)$ for $x = 1.57$; compare the results.

C **65.** (a) Use a CAS to show that if $k$ is a positive constant, then

$$\lim_{x \to +\infty} x(k^{1/x} - 1) = \ln k$$

(b) Confirm this result using L'Hôpital's rule. [*Hint:* Express the limit in terms of $t = 1/x$.]

(c) If $n$ is a positive integer, then it follows from part (a) with $x = n$ that the approximation

$$n(\sqrt[n]{k} - 1) \approx \ln k$$

should be good when $n$ is large. Use this result and the square root key on a calculator to approximate the values of $\ln 0.3$ and $\ln 2$ with $n = 1024$, then compare the values obtained with values of the logarithms generated directly from the calculator. [*Hint:* The $n$th roots for which $n$ is a power of 2 can be obtained as successive square roots.]

**66.** Find all values of $k$ and $l$ such that

$$\lim_{x \to 0} \frac{k + \cos lx}{x^2} = -4$$

**FOCUS ON CONCEPTS**

**67.** Let $f(x) = x^2 \sin(1/x)$.

(a) Are the limits $\lim_{x \to 0^+} f(x)$ and $\lim_{x \to 0^-} f(x)$ indeterminate forms?

(b) Use a graphing utility to generate the graph of $f$, and use the graph to make conjectures about the limits in part (a).

(c) Use the Squeezing Theorem (1.6.4) to confirm that your conjectures in part (b) are correct.

**68.** (a) Explain why L'Hôpital's rule does not apply to the problem

$$\lim_{x \to 0} \frac{x^2 \sin(1/x)}{\sin x}$$

(b) Find the limit.

**69.** Find $\lim_{x \to 0^+} \dfrac{x \sin(1/x)}{\sin x}$ if it exists.

**70.** Suppose that functions $f$ and $g$ are differentiable at $x = a$ and that $f(a) = g(a) = 0$. If $g'(a) \neq 0$, show that

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \frac{f'(a)}{g'(a)}$$

without using L'Hôpital's rule. [*Hint:* Divide the numerator and denominator of $f(x)/g(x)$ by $x - a$ and use the definitions for $f'(a)$ and $g'(a)$.]

**71.** **Writing** Were we to use L'Hôpital's rule to evaluate either

$$\lim_{x \to 0} \frac{\sin x}{x} \quad \text{or} \quad \lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x$$

we could be accused of circular reasoning. Explain why.

**72.** **Writing** Exercise 58 shows that the indeterminate forms $0^0$ and $\infty^0$ can assume any positive real value. However, it is often the case that these indeterminate forms have value 1. Read the article "Indeterminate Forms of Exponential Type" by John Baxley and Elmer Hayashi in the June–July 1978 issue of *The American Mathematical Monthly*, and write a short report on why this is the case.

## QUICK CHECK ANSWERS 3.6

**1.** (a) yes (b) no (c) yes **2.** (a) $\frac{1}{2}$ (b) does not exist (c) 2 **3.** $+\infty$

## CHAPTER 3 REVIEW EXERCISES

Graphing Utility

**1–2** (a) Find $dy/dx$ by differentiating implicitly. (b) Solve the equation for $y$ as a function of $x$, and find $dy/dx$ from that equation. (c) Confirm that the two results are consistent by expressing the derivative in part (a) as a function of $x$ alone. ■

**1.** $x^3 + xy - 2x = 1$ **2.** $xy = x - y$

**3–6** Find $dy/dx$ by implicit differentiation. ■

**3.** $\dfrac{1}{y} + \dfrac{1}{x} = 1$ **4.** $x^3 - y^3 = 6xy$

**5.** $\sec(xy) = y$ **6.** $x^2 = \dfrac{\cot y}{1 + \csc y}$

**7–8** Find $d^2y/dx^2$ by implicit differentiation. ■

**7.** $3x^2 - 4y^2 = 7$ **8.** $2xy - y^2 = 3$

**9.** Use implicit differentiation to find the slope of the tangent line to the curve $y = x \tan(\pi y/2)$, $x > 0$, $y > 0$ (***the quadratrix of Hippias***) at the point $\left(\frac{1}{2}, \frac{1}{2}\right)$.

**10.** At what point(s) is the tangent line to the curve $y^2 = 2x^3$ perpendicular to the line $4x - 3y + 1 = 0$?

**11.** Prove that if $P$ and $Q$ are two distinct points on the rotated ellipse $x^2 + xy + y^2 = 4$ such that $P$, $Q$, and the origin are collinear, then the tangent lines to the ellipse at $P$ and $Q$ are parallel.

**12.** Find the coordinates of the point in the first quadrant at which the tangent line to the curve $x^3 - xy + y^3 = 0$ is parallel to the $x$-axis.

**13.** Find the coordinates of the point in the first quadrant at which the tangent line to the curve $x^3 - xy + y^3 = 0$ is parallel to the $y$-axis.

**14.** Use implicit differentiation to show that the equation of the tangent line to the curve $y^2 = kx$ at $(x_0, y_0)$ is

$$y_0 y = \tfrac{1}{2}k(x + x_0)$$

**15–16** Find $dy/dx$ by first using algebraic properties of the natural logarithm function. ■

**15.** $y = \ln\left(\dfrac{(x+1)(x+2)^2}{(x+3)^3(x+4)^4}\right)$ **16.** $y = \ln\left(\dfrac{\sqrt{x}\sqrt[3]{x+1}}{\sin x \sec x}\right)$

**17–34** Find $dy/dx$. ■

**17.** $y = \ln 2x$ **18.** $y = (\ln x)^2$

**19.** $y = \sqrt[3]{\ln x + 1}$ **20.** $y = \ln(\sqrt[3]{x+1})$

**21.** $y = \log(\ln x)$ **22.** $y = \dfrac{1 + \log x}{1 - \log x}$

**23.** $y = \ln(x^{3/2}\sqrt{1+x^4})$ **24.** $y = \ln\left(\dfrac{\sqrt{x}\cos x}{1+x^2}\right)$

**25.** $y = e^{\ln(x^2+1)}$ **26.** $y = \ln\left(\dfrac{1 + e^x + e^{2x}}{1 - e^{3x}}\right)$

**27.** $y = 2xe^{\sqrt{x}}$ **28.** $y = \dfrac{a}{1 + be^{-x}}$

**29.** $y = \dfrac{1}{\pi}\tan^{-1} 2x$ **30.** $y = 2^{\sin^{-1} x}$

**31.** $y = x^{(e^x)}$ **32.** $y = (1+x)^{1/x}$

**33.** $y = \sec^{-1}(2x+1)$ **34.** $y = \sqrt{\cos^{-1} x^2}$

**35–36** Find $dy/dx$ using logarithmic differentiation. ■

**35.** $y = \dfrac{x^3}{\sqrt{x^2+1}}$ **36.** $y = \sqrt[3]{\dfrac{x^2-1}{x^2+1}}$

**37.** (a) Make a conjecture about the shape of the graph of $y = \frac{1}{2}x - \ln x$, and draw a rough sketch.
(b) Check your conjecture by graphing the equation over the interval $0 < x < 5$ with a graphing utility.
(c) Show that the slopes of the tangent lines to the curve at $x = 1$ and $x = e$ have opposite signs.
(d) What does part (c) imply about the existence of a horizontal tangent line to the curve? Explain.
(e) Find the exact $x$-coordinates of all horizontal tangent lines to the curve.

**38.** Recall from Section 0.5 that the loudness $\beta$ of a sound in decibels (dB) is given by $\beta = 10\log(I/I_0)$, where $I$ is the intensity of the sound in watts per square meter ($W/m^2$) and $I_0$ is a constant that is approximately the intensity of a sound at the threshold of human hearing. Find the rate of change of $\beta$ with respect to $I$ at the point where
(a) $I/I_0 = 10$ (b) $I/I_0 = 100$ (c) $I/I_0 = 1000$.

**39.** A particle is moving along the curve $y = x\ln x$. Find all values of $x$ at which the rate of change of $y$ with respect to time is three times that of $x$. [Assume that $dx/dt$ is never zero.]

**40.** Find the equation of the tangent line to the graph of $y = \ln(5 - x^2)$ at $x = 2$.

**41.** Find the value of $b$ so that the line $y = x$ is tangent to the graph of $y = \log_b x$. Confirm your result by graphing both $y = x$ and $y = \log_b x$ in the same coordinate system.

**42.** In each part, find the value of $k$ for which the graphs of $y = f(x)$ and $y = \ln x$ share a common tangent line at their point of intersection. Confirm your result by graphing $y = f(x)$ and $y = \ln x$ in the same coordinate system.
(a) $f(x) = \sqrt{x} + k$ (b) $f(x) = k\sqrt{x}$

**43.** If $f$ and $g$ are inverse functions and $f$ is differentiable on its domain, must $g$ be differentiable on its domain? Give a reasonable informal argument to support your answer.

**44.** In each part, find $(f^{-1})'(x)$ using Formula (2) of Section 3.3, and check your answer by differentiating $f^{-1}$ directly.
(a) $f(x) = 3/(x+1)$ (b) $f(x) = \sqrt{e^x}$

**45.** Find a point on the graph of $y = e^{3x}$ at which the tangent line passes through the origin.

**46.** Show that the rate of change of $y = 5000e^{1.07x}$ is proportional to $y$.

**47.** Show that the rate of change of $y = 3^{2x}5^{7x}$ is proportional to $y$.

**48.** The equilibrium constant $k$ of a balanced chemical reaction changes with the absolute temperature $T$ according to the law

$$k = k_0 \exp\left(-\frac{q(T - T_0)}{2T_0 T}\right)$$

where $k_0$, $q$, and $T_0$ are constants. Find the rate of change of $k$ with respect to $T$.

**49.** Show that the function $y = e^{ax}\sin bx$ satisfies

$$y'' - 2ay' + (a^2 + b^2)y = 0$$

for any real constants $a$ and $b$.

**50.** Show that the function $y = \tan^{-1} x$ satisfies

$$y'' = -2\sin y \cos^3 y$$

**51.** Suppose that the population of deer on an island is modeled by the equation

$$P(t) = \frac{95}{5 - 4e^{-t/4}}$$

where $P(t)$ is the number of deer $t$ weeks after an initial observation at time $t = 0$.
(a) Use a graphing utility to graph the function $P(t)$.
(b) In words, explain what happens to the population over time. Check your conclusion by finding $\lim_{t\to+\infty} P(t)$.
(c) In words, what happens to the *rate* of population growth over time? Check your conclusion by graphing $P'(t)$.

**52.** In each part, find each limit by interpreting the expression as an appropriate derivative.

(a) $\lim\limits_{h\to 0} \dfrac{(1+h)^\pi - 1}{h}$ (b) $\lim\limits_{x\to e} \dfrac{1 - \ln x}{(x-e)\ln x}$

**53.** Suppose that $\lim f(x) = \pm\infty$ and $\lim g(x) = \pm\infty$. In each of the four possible cases, state whether $\lim[f(x) - g(x)]$ is an indeterminate form, and give a reasonable informal argument to support your answer.

**54.** (a) Under what conditions will a limit of the form

$$\lim_{x \to a} [f(x)/g(x)]$$

be an indeterminate form?

(b) If $\lim_{x \to a} g(x) = 0$, must $\lim_{x \to a}[f(x)/g(x)]$ be an indeterminate form? Give some examples to support your answer.

**55–58** Evaluate the given limit. ■

**55.** $\lim_{x \to +\infty} (e^x - x^2)$

**56.** $\lim_{x \to 1} \sqrt{\dfrac{\ln x}{x^4 - 1}}$

**57.** $\lim_{x \to 0} \dfrac{x^2 e^x}{\sin^2 3x}$

**58.** $\lim_{x \to 0} \dfrac{a^x - 1}{x}, \quad a > 0$

**59.** An oil slick on a lake is surrounded by a floating circular containment boom. As the boom is pulled in, the circular containment area shrinks. If the boom is pulled in at the rate of 5 m/min, at what rate is the containment area shrinking when the containment area has a diameter of 100 m?

**60.** The hypotenuse of a right triangle is growing at a constant rate of $a$ centimeters per second and one leg is decreasing at a constant rate of $b$ centimeters per second. How fast is the acute angle between the hypotenuse and the other leg changing at the instant when both legs are 1 cm?

**61.** In each part, use the given information to find $\Delta x$, $\Delta y$, and $dy$.

(a) $y = 1/(x - 1)$; $x$ decreases from 2 to 1.5.

(b) $y = \tan x$; $x$ increases from $-\pi/4$ to 0.

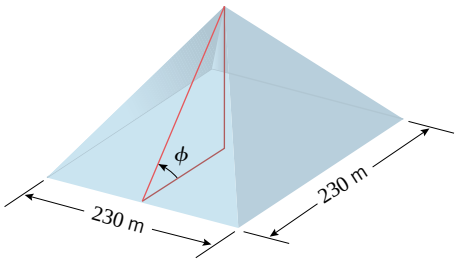
(c) $y = \sqrt{25 - x^2}$; $x$ increases from 0 to 3.

**62.** Use an appropriate local linear approximation to estimate the value of $\cot 46°$, and compare your answer to the value obtained with a calculating device.

**63.** The base of the Great Pyramid at Giza is a square that is 230 m on each side.

(a) As illustrated in the accompanying figure, suppose that an archaeologist standing at the center of a side measures the angle of elevation of the apex to be $\phi = 51°$ with an error of $\pm 0.5°$. What can the archaeologist reasonably say about the height of the pyramid?

(b) Use differentials to estimate the allowable error in the elevation angle that will ensure that the error in calculating the height is at most $\pm 5$ m.



▲ **Figure Ex-63**

## CHAPTER 3 MAKING CONNECTIONS

In these exercises we explore an application of exponential functions to radioactive decay, and we consider another approach to computing the derivative of the natural exponential function.

**1.** Consider a simple model of radioactive decay. We assume that given any quantity of a radioactive element, the fraction of the quantity that decays over a period of time will be a constant that depends on only the particular element and the length of the time period. We choose a time parameter $-\infty < t < +\infty$ and let $A = A(t)$ denote the amount of the element remaining at time $t$. We also choose units of measure such that the initial amount of the element is $A(0) = 1$, and we let $b = A(1)$ denote the amount at time $t = 1$. Prove that the function $A(t)$ has the following properties.

(a) $A(-t) = \dfrac{1}{A(t)}$ [*Hint:* For $t > 0$, you can interpret $A(t)$ as the fraction of any given amount that remains after a time period of length $t$.]

(b) $A(s + t) = A(s) \cdot A(t)$ [*Hint:* First consider positive $s$ and $t$. For the other cases use the property in part (a).]

(c) If $n$ is any nonzero integer, then

$$A\left(\frac{1}{n}\right) = (A(1))^{1/n} = b^{1/n}$$

(d) If $m$ and $n$ are integers with $n \neq 0$, then

$$A\left(\frac{m}{n}\right) = (A(1))^{m/n} = b^{m/n}$$

(e) Assuming that $A(t)$ is a continuous function of $t$, then $A(t) = b^t$. [*Hint:* Prove that if two continuous functions agree on the set of rational numbers, then they are equal.]

(f) If we replace the assumption that $A(0) = 1$ by the condition $A(0) = A_0$, prove that $A = A_0 b^t$.

**2.** Refer to Figure 1.3.4.

(a) Make the substitution $h = 1/x$ and conclude that

$$(1+h)^{1/h} < e < (1-h)^{-1/h} \quad \text{for } h > 0$$

and

$$(1-h)^{-1/h} < e < (1+h)^{1/h} \quad \text{for } h < 0$$

(b) Use the inequalities in part (a) and the Squeezing Theorem to prove that

$$\lim_{h \to 0} \frac{e^h - 1}{h} = 1$$

(c) Explain why the limit in part (b) confirms Figure 0.5.4.

(d) Use the limit in part (b) to prove that

$$\frac{d}{dx}(e^x) = e^x$$

*Derivatives can help to find the most cost-effective location for an offshore oil-drilling rig.*

# 4 THE DERIVATIVE IN GRAPHING AND APPLICATIONS

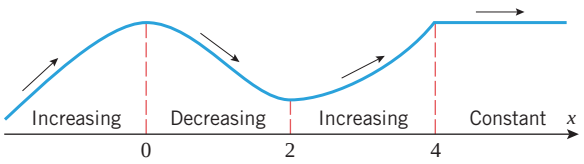
In this chapter we will study various applications of the derivative. For example, we will use methods of calculus to analyze functions and their graphs. In the process, we will show how calculus and graphing utilities, working together, can provide most of the important information about the behavior of functions. Another important application of the derivative will be in the solution of optimization problems. For example, if time is the main consideration in a problem, we might be interested in finding the quickest way to perform a task, and if cost is the main consideration, we might be interested in finding the least expensive way to perform a task. Mathematically, optimization problems can be reduced to finding the largest or smallest value of a function on some interval, and determining where the largest or smallest value occurs. Using the derivative, we will develop the mathematical tools necessary for solving such problems. We will also use the derivative to study the motion of a particle moving along a line, and we will show how the derivative can help us to approximate solutions of equations.

## 4.1 ANALYSIS OF FUNCTIONS I: INCREASE, DECREASE, AND CONCAVITY

*Although graphing utilities are useful for determining the general shape of a graph, many problems require more precision than graphing utilities are capable of producing. The purpose of this section is to develop mathematical tools that can be used to determine the exact shape of a graph and the precise locations of its key features.*

### INCREASING AND DECREASING FUNCTIONS

The terms *increasing*, *decreasing*, and *constant* are used to describe the behavior of a function as we travel left to right along its graph. For example, the function graphed in Figure 4.1.1 can be described as increasing to the left of $x = 0$, decreasing from $x = 0$ to $x = 2$, increasing from $x = 2$ to $x = 4$, and constant to the right of $x = 4$.



▶ **Figure 4.1.1**

The following definition, which is illustrated in Figure 4.1.2, expresses these intuitive ideas precisely.

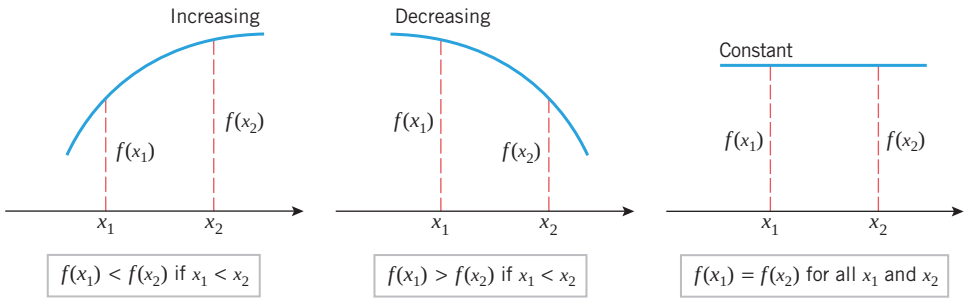
The definitions of "increasing," "decreasing," and "constant" describe the behavior of a function on an *interval* and not at a point. In particular, it is not inconsistent to say that the function in Figure 4.1.1 is decreasing on the interval $[0, 2]$ and increasing on the interval $[2, 4]$.

**4.1.1 DEFINITION** Let $f$ be defined on an interval, and let $x_1$ and $x_2$ denote points in that interval.

(a) $f$ is ***increasing*** on the interval if $f(x_1) < f(x_2)$ whenever $x_1 < x_2$.

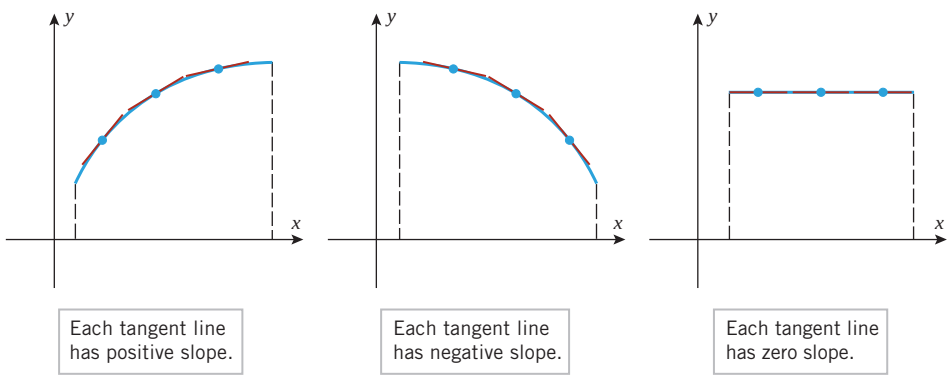
(b) $f$ is ***decreasing*** on the interval if $f(x_1) > f(x_2)$ whenever $x_1 < x_2$.

(c) $f$ is ***constant*** on the interval if $f(x_1) = f(x_2)$ for all points $x_1$ and $x_2$.



▶ **Figure 4.1.2**

Figure 4.1.3 suggests that a differentiable function $f$ is increasing on any interval where each tangent line to its graph has positive slope, is decreasing on any interval where each tangent line to its graph has negative slope, and is constant on any interval where each tangent line to its graph has zero slope. This intuitive observation suggests the following important theorem that will be proved in Section 4.8.



▶ **Figure 4.1.3**

Observe that the derivative conditions in Theorem 4.1.2 are only required to hold *inside* the interval $[a, b]$, even though the conclusions apply to the entire interval.

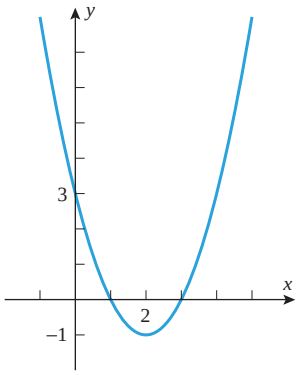
**4.1.2 THEOREM** *Let $f$ be a function that is continuous on a closed interval $[a, b]$ and differentiable on the open interval $(a, b)$.*

*(a) If $f'(x) > 0$ for every value of $x$ in $(a, b)$, then $f$ is increasing on $[a, b]$.*

*(b) If $f'(x) < 0$ for every value of $x$ in $(a, b)$, then $f$ is decreasing on $[a, b]$.*

*(c) If $f'(x) = 0$ for every value of $x$ in $(a, b)$, then $f$ is constant on $[a, b]$.*

Although stated for closed intervals, Theorem 4.1.2 is applicable on any interval on which $f$ is continuous. For example, if $f$ is continuous on $[a, +\infty)$ and $f'(x) > 0$ on $(a, +\infty)$, then $f$ is increasing on $[a, +\infty)$; and if $f$ is continuous on $(-\infty, +\infty)$ and $f'(x) < 0$ on $(-\infty, +\infty)$, then $f$ is decreasing on $(-\infty, +\infty)$.



$f(x) = x^2 - 4x + 3$

▶ Figure 4.1.4

▶ **Example 1** Find the intervals on which $f(x) = x^2 - 4x + 3$ is increasing and the intervals on which it is decreasing.

***Solution.*** The graph of $f$ in Figure 4.1.4 suggests that $f$ is decreasing for $x \le 2$ and increasing for $x \ge 2$. To confirm this, we analyze the sign of $f'$. The derivative of $f$ is

$$f'(x) = 2x - 4 = 2(x - 2)$$

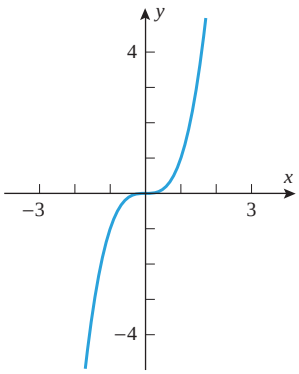
It follows that

$$f'(x) < 0 \quad \text{if} \quad x < 2$$
$$f'(x) > 0 \quad \text{if} \quad 2 < x$$

Since $f$ is continuous everywhere, it follows from the comment after Theorem 4.1.2 that

$$f \text{ is decreasing on } (-\infty, 2]$$
$$f \text{ is increasing on } [2, +\infty)$$

These conclusions are consistent with the graph of $f$ in Figure 4.1.4. ◀



$f(x) = x^3$

▶ Figure 4.1.5

▶ **Example 2** Find the intervals on which $f(x) = x^3$ is increasing and the intervals on which it is decreasing.

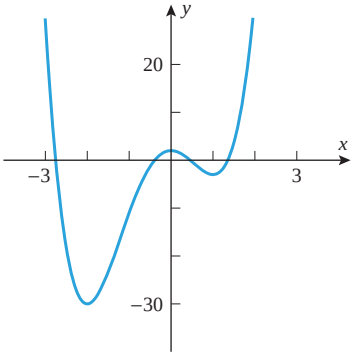
***Solution.*** The graph of $f$ in Figure 4.1.5 suggests that $f$ is increasing over the entire $x$-axis. To confirm this, we differentiate $f$ to obtain $f'(x) = 3x^2$. Thus,

$$f'(x) > 0 \quad \text{if} \quad x < 0$$
$$f'(x) > 0 \quad \text{if} \quad 0 < x$$

Since $f$ is continuous everywhere,

$$f \text{ is increasing on } (-\infty, 0]$$
$$f \text{ is increasing on } [0, +\infty)$$

Since $f$ is increasing on the adjacent intervals $(-\infty, 0]$ and $[0, +\infty)$, it follows that $f$ is increasing on their union $(-\infty, +\infty)$ (see Exercise 59). ◀



$f(x) = 3x^4 + 4x^3 - 12x^2 + 2$

▶ Figure 4.1.6

▶ **Example 3**

(a) Use the graph of $f(x) = 3x^4 + 4x^3 - 12x^2 + 2$ in Figure 4.1.6 to make a conjecture about the intervals on which $f$ is increasing or decreasing.

(b) Use Theorem 4.1.2 to determine whether your conjecture is correct.

***Solution (a).*** The graph suggests that the function $f$ is decreasing if $x \le -2$, increasing if $-2 \le x \le 0$, decreasing if $0 \le x \le 1$, and increasing if $x \ge 1$.

***Solution (b).*** Differentiating $f$ we obtain

$$f'(x) = 12x^3 + 12x^2 - 24x = 12x(x^2 + x - 2) = 12x(x + 2)(x - 1)$$

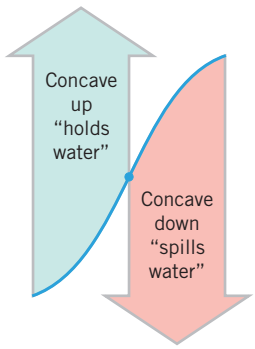
The sign analysis of $f'$ in Table 4.1.1 can be obtained using the method of test points discussed in Web Appendix E. The conclusions in Table 4.1.1 confirm the conjecture in part (a). ◀

**Table 4.1.1**

| INTERVAL | $(12x)(x+2)(x-1)$ | $f'(x)$ | CONCLUSION |
|---|---|---|---|
| $x < -2$ | $(-)(-)(-)$ | $-$ | $f$ is decreasing on $(-\infty, -2]$ |
| $-2 < x < 0$ | $(-)(+)(-)$ | $+$ | $f$ is increasing on $[-2, 0]$ |
| $0 < x < 1$ | $(+)(+)(-)$ | $-$ | $f$ is decreasing on $[0, 1]$ |
| $1 < x$ | $(+)(+)(+)$ | $+$ | $f$ is increasing on $[1, +\infty)$ |

## CONCAVITY

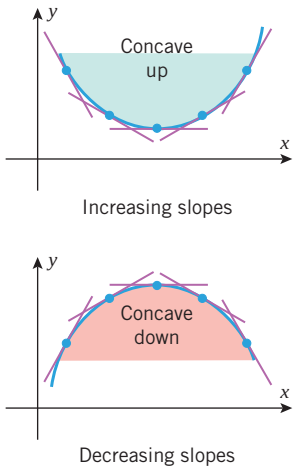
Although the sign of the derivative of $f$ reveals where the graph of $f$ is increasing or decreasing, it does not reveal the direction of *curvature*. For example, the graph is increasing on both sides of the point in Figure 4.1.7, but on the left side it has an upward curvature ("holds water") and on the right side it has a downward curvature ("spills water"). On intervals where the graph of $f$ has upward curvature we say that $f$ is *concave up*, and on intervals where the graph has downward curvature we say that $f$ is *concave down*.



▶ **Figure 4.1.7**

Figure 4.1.8 suggests two ways to characterize the concavity of a differentiable function $f$ on an open interval:

- $f$ is concave up on an open interval if its tangent lines have increasing slopes on that interval and is concave down if they have decreasing slopes.
- $f$ is concave up on an open interval if its graph lies above its tangent lines on that interval and is concave down if it lies below its tangent lines.



▶ **Figure 4.1.8**

Our formal definition for "concave up" and "concave down" corresponds to the first of these characterizations.

**4.1.3 DEFINITION** If $f$ is differentiable on an open interval, then $f$ is said to be ***concave up*** on the open interval if $f'$ is increasing on that interval, and $f$ is said to be ***concave down*** on the open interval if $f'$ is decreasing on that interval.

Since the slopes of the tangent lines to the graph of a differentiable function $f$ are the values of its derivative $f'$, it follows from Theorem 4.1.2 (applied to $f'$ rather than $f$) that $f'$ will be increasing on intervals where $f''$ is positive and that $f'$ will be decreasing on intervals where $f''$ is negative. Thus, we have the following theorem.

**4.1.4 THEOREM** *Let $f$ be twice differentiable on an open interval.*

(*a*) *If $f''(x) > 0$ for every value of $x$ in the open interval, then $f$ is concave up on that interval.*

(*b*) *If $f''(x) < 0$ for every value of $x$ in the open interval, then $f$ is concave down on that interval.*

▶ **Example 4** Figure 4.1.4 suggests that the function $f(x) = x^2 - 4x + 3$ is concave up on the interval $(-\infty, +\infty)$. This is consistent with Theorem 4.1.4, since $f'(x) = 2x - 4$ and $f''(x) = 2$, so

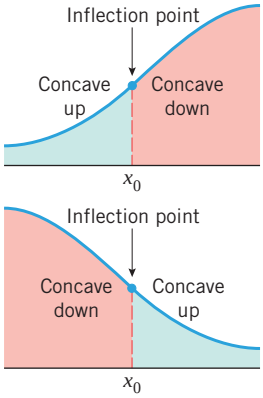
$$f''(x) > 0 \quad \text{on the interval } (-\infty, +\infty)$$

Also, Figure 4.1.5 suggests that $f(x) = x^3$ is concave down on the interval $(-\infty, 0)$ and concave up on the interval $(0, +\infty)$. This agrees with Theorem 4.1.4, since $f'(x) = 3x^2$ and $f''(x) = 6x$, so

$$f''(x) < 0 \quad \text{if } x < 0 \quad \text{and} \quad f''(x) > 0 \quad \text{if } x > 0 \ \blacktriangleleft$$

## INFLECTION POINTS

We see from Example 4 and Figure 4.1.5 that the graph of $f(x) = x^3$ changes from concave down to concave up at $x = 0$. Points where a curve changes from concave up to concave down or vice versa are of special interest, so there is some terminology associated with them.



▶ Figure 4.1.9

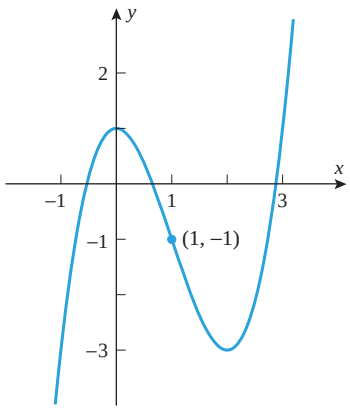
**4.1.5 DEFINITION** If $f$ is continuous on an open interval containing a value $x_0$, and if $f$ changes the direction of its concavity at the point $(x_0, f(x_0))$, then we say that $f$ has an ***inflection point at $x_0$***, and we call the point $(x_0, f(x_0))$ on the graph of $f$ an ***inflection point*** of $f$ (Figure 4.1.9).

▶ **Example 5** Figure 4.1.10 shows the graph of the function $f(x) = x^3 - 3x^2 + 1$. Use the first and second derivatives of $f$ to determine the intervals on which $f$ is increasing, decreasing, concave up, and concave down. Locate all inflection points and confirm that your conclusions are consistent with the graph.

***Solution.*** Calculating the first two derivatives of $f$ we obtain

$$f'(x) = 3x^2 - 6x = 3x(x - 2)$$
$$f''(x) = 6x - 6 = 6(x - 1)$$

The sign analysis of these derivatives is shown in the following tables:



$f(x) = x^3 - 3x^2 + 1$

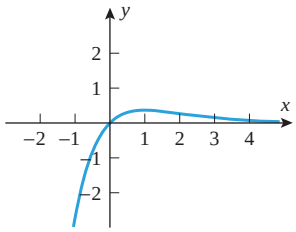
▶ Figure 4.1.10

| INTERVAL | $(3x)(x-2)$ | $f'(x)$ | CONCLUSION |
|---|---|---|---|
| $x < 0$ | (−)(−) | + | $f$ is increasing on $(-\infty, 0]$ |
| $0 < x < 2$ | (+)(−) | − | $f$ is decreasing on $[0, 2]$ |
| $x > 2$ | (+)(+) | + | $f$ is increasing on $[2, +\infty)$ |

| INTERVAL | $6(x-1)$ | $f''(x)$ | CONCLUSION |
|---|---|---|---|
| $x < 1$ | (−) | − | $f$ is concave down on $(-\infty, 1)$ |
| $x > 1$ | (+) | + | $f$ is concave up on $(1, +\infty)$ |

The second table shows that there is an inflection point at $x = 1$, since $f$ changes from concave down to concave up at that point. The inflection point is $(1, f(1)) = (1, -1)$. All of these conclusions are consistent with the graph of $f$. ◀

One can correctly guess from Figure 4.1.10 that the function $f(x) = x^3 - 3x^2 + 1$ has an inflection point at $x = 1$ without actually computing derivatives. However, sometimes changes in concavity are so subtle that calculus is essential to confirm their existence and identify their location. Here is an example.



$f(x) = xe^{-x}$

▶ Figure 4.1.11

▶ **Example 6** Figure 4.1.11 suggests that the function $f(x) = xe^{-x}$ has an inflection point but its exact location is not evident from the graph in this figure. Use the first and second derivatives of $f$ to determine the intervals on which $f$ is increasing, decreasing, concave up, and concave down. Locate all inflection points.

***Solution.*** Calculating the first two derivatives of $f$ we obtain (verify)

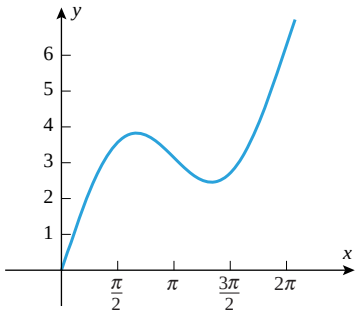
$$f'(x) = (1 - x)e^{-x}$$
$$f''(x) = (x - 2)e^{-x}$$

Keeping in mind that $e^{-x}$ is positive for all $x$, the sign analysis of these derivatives is easily determined:

| INTERVAL | $(1-x)(e^{-x})$ | $f'(x)$ | CONCLUSION |
|---|---|---|---|
| $x < 1$ | $(+)(+)$ | $+$ | $f$ is increasing on $(-\infty, 1]$ |
| $x > 1$ | $(-)(+)$ | $-$ | $f$ is decreasing on $[1, +\infty)$ |

| INTERVAL | $(x-2)(e^{-x})$ | $f''(x)$ | CONCLUSION |
|---|---|---|---|
| $x < 2$ | $(-)(+)$ | $-$ | $f$ is concave down on $(-\infty, 2)$ |
| $x > 2$ | $(+)(+)$ | $+$ | $f$ is concave up on $(2, +\infty)$ |

The second table shows that there is an inflection point at $x = 2$, since $f$ changes from concave down to concave up at that point. All of these conclusions are consistent with the graph of $f$. ◀



$f(x) = x + 2\sin x$

▶ Figure 4.1.12

▶ **Example 7** Figure 4.1.12 shows the graph of the function $f(x) = x + 2\sin x$ over the interval $[0, 2\pi]$. Use the first and second derivatives of $f$ to determine where $f$ is increasing, decreasing, concave up, and concave down. Locate all inflection points and confirm that your conclusions are consistent with the graph.

***Solution.*** Calculating the first two derivatives of $f$ we obtain

$$f'(x) = 1 + 2\cos x$$
$$f''(x) = -2\sin x$$

Since $f'$ is a continuous function, it changes sign on the interval $(0, 2\pi)$ only at points where $f'(x) = 0$ (why?). These values are solutions of the equation

$$1 + 2\cos x = 0 \quad \text{or equivalently} \quad \cos x = -\tfrac{1}{2}$$

There are two solutions of this equation in the interval $(0, 2\pi)$, namely, $x = 2\pi/3$ and $x = 4\pi/3$ (verify). Similarly, $f''$ is a continuous function, so its sign changes in the interval $(0, 2\pi)$ will occur only at values of $x$ for which $f''(x) = 0$. These values are solutions of the equation

$$-2\sin x = 0$$

There is one solution of this equation in the interval $(0, 2\pi)$, namely, $x = \pi$. With the help of these "sign transition points" we obtain the sign analysis shown in the following tables:

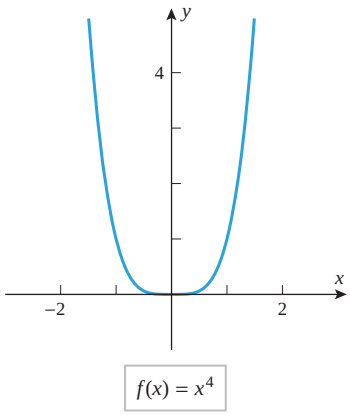
| INTERVAL | $f'(x) = 1 + 2\cos x$ | CONCLUSION |
|---|---|---|
| $0 < x < 2\pi/3$ | + | $f$ is increasing on $[0, 2\pi/3]$ |
| $2\pi/3 < x < 4\pi/3$ | − | $f$ is decreasing on $[2\pi/3, 4\pi/3]$ |
| $4\pi/3 < x < 2\pi$ | + | $f$ is increasing on $[4\pi/3, 2\pi]$ |

The signs in the two tables of Example 7 can be obtained either using the method of test points or using the unit circle definition of the sine and cosine functions.

| INTERVAL | $f''(x) = -2\sin x$ | CONCLUSION |
|---|---|---|
| $0 < x < \pi$ | − | $f$ is concave down on $(0, \pi)$ |
| $\pi < x < 2\pi$ | + | $f$ is concave up on $(\pi, 2\pi)$ |

The second table shows that there is an inflection point at $x = \pi$, since $f$ changes from concave down to concave up at that point. All of these conclusions are consistent with the graph of $f$. ◀

In the preceding examples the inflection points of $f$ occurred wherever $f''(x) = 0$. However, this is not always the case. Here is a specific example.



▶ Figure 4.1.13

▶ **Example 8** Find the inflection points, if any, of $f(x) = x^4$.

***Solution.*** Calculating the first two derivatives of $f$ we obtain

$$f'(x) = 4x^3$$

$$f''(x) = 12x^2$$

Since $f''(x)$ is positive for $x < 0$ and for $x > 0$, the function $f$ is concave up on the interval $(-\infty, 0)$ and on the interval $(0, +\infty)$. Thus, there is no change in concavity and hence no inflection point at $x = 0$, even though $f''(0) = 0$ (Figure 4.1.13). ◀

Give an argument to show that the function $f(x) = x^4$ graphed in Figure 4.1.13 is concave up on the interval $(-\infty, +\infty)$.

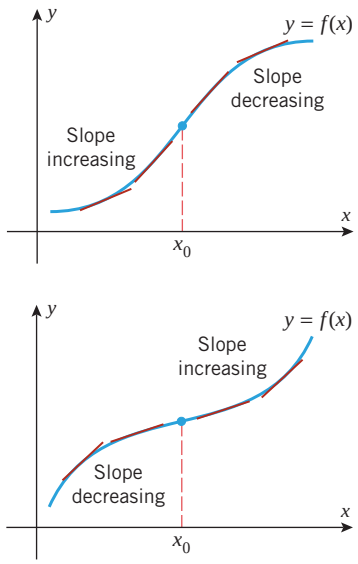
We will see later that if a function $f$ has an inflection point at $x = x_0$ and $f''(x_0)$ exists, then $f''(x_0) = 0$. Also, we will see in Section 4.3 that an inflection point may also occur where $f''(x)$ is not defined.

## INFLECTION POINTS IN APPLICATIONS

Inflection points of a function $f$ are those points on the graph of $y = f(x)$ where the slopes of the tangent lines change from increasing to decreasing or vice versa (Figure 4.1.14). Since the slope of the tangent line at a point on the graph of $y = f(x)$ can be interpreted as the rate of change of $y$ with respect to $x$ at that point, we can interpret inflection points in the following way:

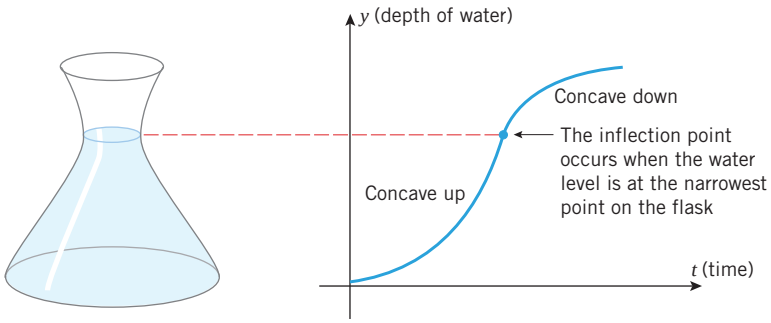
*Inflection points mark the places on the curve $y = f(x)$ where the rate of change of $y$ with respect to $x$ changes from increasing to decreasing, or vice versa.*

This is a subtle idea, since we are dealing with a change in a rate of change. It can help with your understanding of this idea to realize that inflection points may have interpretations in more familiar contexts. For example, consider the statement "Oil prices rose sharply during the first half of the year but have since begun to level off." If the price of oil is plotted as a function of time of year, this statement suggests the existence of an inflection point



▶ Figure 4.1.14

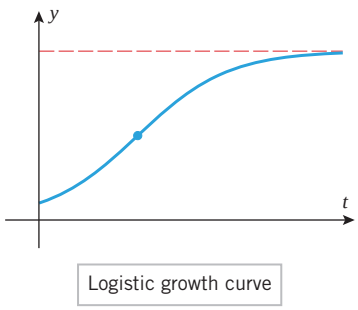
on the graph near the end of June. (Why?) To give a more visual example, consider the flask shown in Figure 4.1.15. Suppose that water is added to the flask so that the volume increases at a constant rate with respect to the time $t$, and let us examine the rate at which the water level $y$ rises with respect to $t$. Initially, the level $y$ will rise at a slow rate because of the wide base. However, as the diameter of the flask narrows, the rate at which the level $y$ rises will increase until the level is at the narrow point in the neck. From that point on the rate at which the level rises will decrease as the diameter gets wider and wider. Thus, the narrow point in the neck is the point at which the rate of change of $y$ with respect to $t$ changes from increasing to decreasing.



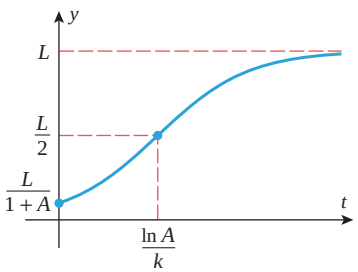
▶ Figure 4.1.15

## LOGISTIC CURVES

When a population grows in an environment in which space or food is limited, the graph of population versus time is typically an S-shaped curve of the form shown in Figure 4.1.16. The scenario described by this curve is a population that grows slowly at first and then more and more rapidly as the number of individuals producing offspring increases. However, at a certain point in time (where the inflection point occurs) the environmental factors begin to show their effect, and the growth rate begins a steady decline. Over an extended period of time the population approaches a limiting value that represents the upper limit on the number of individuals that the available space or food can sustain. Population growth curves of this type are called ***logistic growth curves***.



▲ Figure 4.1.16



▲ Figure 4.1.17

**▶ Example 9** We will see in a later chapter that logistic growth curves arise from equations of the form

$$y = \frac{L}{1 + Ae^{-kt}} \tag{1}$$

where $y$ is the population at time $t$ ($t \geq 0$) and $A$, $k$, and $L$ are positive constants. Show that Figure 4.1.17 correctly describes the graph of this equation when $A > 1$.

***Solution.*** It follows from (1) that at time $t = 0$ the value of $y$ is

$$y = \frac{L}{1 + A}$$

and it follows from (1) and the fact that $0 < e^{-kt} \leq 1$ for $t \geq 0$ that

$$\frac{L}{1 + A} \leq y < L \tag{2}$$

(verify). This is consistent with the graph in Figure 4.1.17. The horizontal asymptote at $y = L$ is confirmed by the limit

$$\lim_{t \to +\infty} y = \lim_{t \to +\infty} \frac{L}{1 + Ae^{-kt}} = \frac{L}{1 + 0} = L \tag{3}$$

Physically, Formulas (2) and (3) tell us that $L$ is an upper limit on the population and that the population approaches this limit over time. Again, this is consistent with the graph in Figure 4.1.17.

To investigate intervals of increase and decrease, concavity, and inflection points, we need the first and second derivatives of $y$ with respect to $t$. By multiplying both sides of Equation (1) by $e^{kt}(1 + Ae^{-kt})$, we can rewrite (1) as

$$ye^{kt} + Ay = Le^{kt}$$

Using implicit differentiation, we can derive that

$$\frac{dy}{dt} = \frac{k}{L}y(L - y) \tag{4}$$

$$\frac{d^2y}{dt^2} = \frac{k^2}{L^2}y(L - y)(L - 2y) \tag{5}$$

(Exercise 70). Since $k > 0$, $y > 0$, and $L - y > 0$, it follows from (4) that $dy/dt > 0$ for all $t$. Thus, $y$ is always increasing, which is consistent with Figure 4.1.17.

Since $y > 0$ and $L - y > 0$, it follows from (5) that

$$\frac{d^2y}{dt^2} > 0 \quad \text{if} \quad L - 2y > 0$$

$$\frac{d^2y}{dt^2} < 0 \quad \text{if} \quad L - 2y < 0$$

Thus, the graph of $y$ versus $t$ is concave up if $y < L/2$, concave down if $y > L/2$, and has an inflection point where $y = L/2$, all of which is consistent with Figure 4.1.17.

Finally, we leave it for you to solve the equation

$$\frac{L}{2} = \frac{L}{1 + Ae^{-kt}}$$

for $t$ to show that the inflection point occurs at

$$t = \frac{1}{k}\ln A = \frac{\ln A}{k} \tag{6}$$ ◀

## ✔ QUICK CHECK EXERCISES 4.1 (See page 244 for answers.)

**1.** (a) A function $f$ is increasing on $(a, b)$ if _____ whenever $a < x_1 < x_2 < b$.

(b) A function $f$ is decreasing on $(a, b)$ if _____ whenever $a < x_1 < x_2 < b$.

(c) A function $f$ is concave up on $(a, b)$ if $f'$ is _____ on $(a, b)$.

(d) If $f''(a)$ exists and $f$ has an inflection point at $x = a$, then $f''(a)$ _____.

**2.** Let $f(x) = 0.1(x^3 - 3x^2 - 9x)$. Then

$$f'(x) = 0.1(3x^2 - 6x - 9) = 0.3(x + 1)(x - 3)$$

$$f''(x) = 0.6(x - 1)$$

(a) Solutions to $f'(x) = 0$ are $x =$ _____.

(b) The function $f$ is increasing on the interval(s) _____.

(c) The function $f$ is concave down on the interval(s) _____.

(d) _____ is an inflection point on the graph of $f$.

**3.** Suppose that $f(x)$ has derivative $f'(x) = (x - 4)^2e^{-x/2}$. Then $f''(x) = -\frac{1}{2}(x - 4)(x - 8)e^{-x/2}$.

(a) The function $f$ is increasing on the interval(s) _____.

(b) The function $f$ is concave up on the interval(s) _____.

(c) The function $f$ is concave down on the interval(s) _____.

**4.** Consider the statement "The rise in the cost of living slowed during the first half of the year." If we graph the cost of living versus time for the first half of the year, how does the graph reflect this statement?

## EXERCISE SET 4.1 Graphing Utility CAS

### FOCUS ON CONCEPTS

**1.** In each part, sketch the graph of a function $f$ with the stated properties, and discuss the signs of $f'$ and $f''$.

(a) The function $f$ is concave up and increasing on the interval $(-\infty, +\infty)$.

(b) The function $f$ is concave down and increasing on the interval $(-\infty, +\infty)$.

(c) The function $f$ is concave up and decreasing on the interval $(-\infty, +\infty)$.

(d) The function $f$ is concave down and decreasing on the interval $(-\infty, +\infty)$.

**2.** In each part, sketch the graph of a function $f$ with the stated properties.

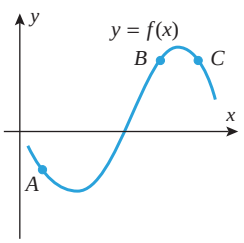
(a) $f$ is increasing on $(-\infty, +\infty)$, has an inflection point at the origin, and is concave up on $(0, +\infty)$.

(b) $f$ is increasing on $(-\infty, +\infty)$, has an inflection point at the origin, and is concave down on $(0, +\infty)$.

(c) $f$ is decreasing on $(-\infty, +\infty)$, has an inflection point at the origin, and is concave up on $(0, +\infty)$.

(d) $f$ is decreasing on $(-\infty, +\infty)$, has an inflection point at the origin, and is concave down on $(0, +\infty)$.

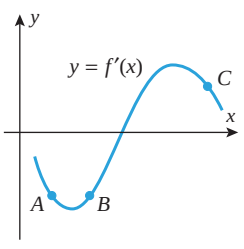
**3.** Use the graph of the equation $y = f(x)$ in the accompanying figure to find the signs of $dy/dx$ and $d^2y/dx^2$ at the points $A$, $B$, and $C$.



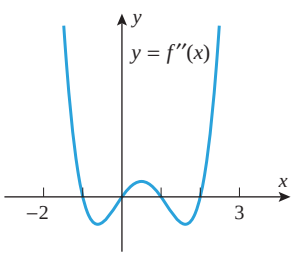
◀ Figure Ex-3

**4.** Use the graph of the equation $y = f'(x)$ in the accompanying figure to find the signs of $dy/dx$ and $d^2y/dx^2$ at the points $A$, $B$, and $C$.

**5.** Use the graph of $y = f''(x)$ in the accompanying figure to determine the $x$-coordinates of all inflection points of $f$. Explain your reasoning.



▲ Figure Ex-4

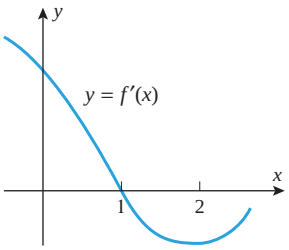


▲ Figure Ex-5

**6.** Use the graph of $y = f'(x)$ in the accompanying figure to replace the question mark with $<$, $=$, or $>$, as appropriate. Explain your reasoning.

(a) $f(0)$ ? $f(1)$ (b) $f(1)$ ? $f(2)$ (c) $f'(0)$ ? 0

(d) $f'(1)$ ? 0 (e) $f''(0)$ ? 0 (f) $f''(2)$ ? 0



◀ Figure Ex-6

**7.** In each part, use the graph of $y = f(x)$ in the accompanying figure to find the requested information.

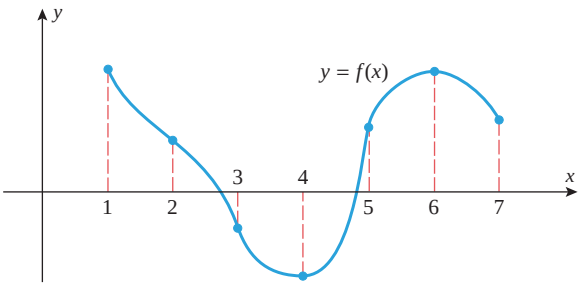
(a) Find the intervals on which $f$ is increasing.

(b) Find the intervals on which $f$ is decreasing.

(c) Find the open intervals on which $f$ is concave up.

(d) Find the open intervals on which $f$ is concave down.

(e) Find all values of $x$ at which $f$ has an inflection point.



▲ Figure Ex-7

**8.** Use the graph in Exercise 7 to make a table that shows the signs of $f'$ and $f''$ over the intervals $(1, 2)$, $(2, 3)$, $(3, 4)$, $(4, 5)$, $(5, 6)$, and $(6, 7)$.

**9–10** A sign chart is presented for the first and second derivatives of a function $f$. Assuming that $f$ is continuous everywhere, find: (a) the intervals on which $f$ is increasing, (b) the intervals on which $f$ is decreasing, (c) the open intervals on which $f$ is concave up, (d) the open intervals on which $f$ is concave down, and (e) the $x$-coordinates of all inflection points. ■

**9.**

| INTERVAL | SIGN OF $f'(x)$ | SIGN OF $f''(x)$ |
|---|---|---|
| $x < 1$ | − | + |
| $1 < x < 2$ | + | + |
| $2 < x < 3$ | + | − |
| $3 < x < 4$ | − | − |
| $4 < x$ | − | + |

**10.**

| INTERVAL | SIGN OF $f'(x)$ | SIGN OF $f''(x)$ |
|---|---|---|
| $x < 1$ | + | + |
| $1 < x < 3$ | + | − |
| $3 < x$ | + | + |

**11–14 True–False** Assume that $f$ is differentiable everywhere. Determine whether the statement is true or false. Explain your answer.

**11.** If $f$ is decreasing on $[0, 2]$, then $f(0) > f(1) > f(2)$.

**12.** If $f'(1) > 0$, then $f$ is increasing on $[0, 2]$.

**13.** If $f$ is increasing on $[0, 2]$, then $f'(1) > 0$.

**14.** If $f'$ is increasing on $[0, 1]$ and $f'$ is decreasing on $[1, 2]$, then $f$ has an inflection point at $x = 1$.

**15–32** Find: (a) the intervals on which $f$ is increasing, (b) the intervals on which $f$ is decreasing, (c) the open intervals on which $f$ is concave up, (d) the open intervals on which $f$ is concave down, and (e) the $x$-coordinates of all inflection points.

**15.** $f(x) = x^2 - 3x + 8$

**16.** $f(x) = 5 - 4x - x^2$

**17.** $f(x) = (2x + 1)^3$

**18.** $f(x) = 5 + 12x - x^3$

**19.** $f(x) = 3x^4 - 4x^3$

**20.** $f(x) = x^4 - 5x^3 + 9x^2$

**21.** $f(x) = \dfrac{x - 2}{(x^2 - x + 1)^2}$

**22.** $f(x) = \dfrac{x}{x^2 + 2}$

**23.** $f(x) = \sqrt[3]{x^2 + x + 1}$

**24.** $f(x) = x^{4/3} - x^{1/3}$

**25.** $f(x) = (x^{2/3} - 1)^2$

**26.** $f(x) = x^{2/3} - x$

**27.** $f(x) = e^{-x^2/2}$

**28.** $f(x) = xe^{x^2}$

**29.** $f(x) = \ln \sqrt{x^2 + 4}$

**30.** $f(x) = x^3 \ln x$

**31.** $f(x) = \tan^{-1}(x^2 - 1)$

**32.** $f(x) = \sin^{-1} x^{2/3}$

**33–38** Analyze the trigonometric function $f$ over the specified interval, stating where $f$ is increasing, decreasing, concave up, and concave down, and stating the $x$-coordinates of all inflection points. Confirm that your results are consistent with the graph of $f$ generated with a graphing utility.

**33.** $f(x) = \sin x - \cos x;\ [-\pi, \pi]$

**34.** $f(x) = \sec x \tan x;\ (-\pi/2, \pi/2)$

**35.** $f(x) = 1 - \tan(x/2);\ (-\pi, \pi)$

**36.** $f(x) = 2x + \cot x;\ (0, \pi)$

**38.** $f(x) = \sin^2 2x;\ [0, \pi]$

**FOCUS ON CONCEPTS**

**39.** In parts (a)–(c), sketch a continuous curve $y = f(x)$ with the stated properties.
(a) $f(2) = 4,\ f'(2) = 0,\ f''(x) > 0$ for all $x$
(b) $f(2) = 4,\ f'(2) = 0,\ f''(x) < 0$ for $x < 2,\ f''(x) > 0$ for $x > 2$
(c) $f(2) = 4,\ f''(x) < 0$ for $x \neq 2$ and $\lim_{x \to 2^+} f'(x) = +\infty,\ \lim_{x \to 2^-} f'(x) = -\infty$

**40.** In each part sketch a continuous curve $y = f(x)$ with the stated properties.
(a) $f(2) = 4,\ f'(2) = 0,\ f''(x) < 0$ for all $x$
(b) $f(2) = 4,\ f'(2) = 0,\ f''(x) > 0$ for $x < 2,\ f''(x) < 0$ for $x > 2$
(c) $f(2) = 4,\ f''(x) > 0$ for $x \neq 2$ and $\lim_{x \to 2^+} f'(x) = -\infty,\ \lim_{x \to 2^-} f'(x) = +\infty$

**41–46** If $f$ is increasing on an interval $[0, b)$, then it follows from Definition 4.1.1 that $f(0) < f(x)$ for each $x$ in the interval $(0, b)$. Use this result in these exercises.

**41.** Show that $\sqrt[3]{1 + x} < 1 + \frac{1}{3}x$ if $x > 0$, and confirm the inequality with a graphing utility. [*Hint:* Show that the function $f(x) = 1 + \frac{1}{3}x - \sqrt[3]{1 + x}$ is increasing on $[0, +\infty)$.]

**42.** Show that $x < \tan x$ if $0 < x < \pi/2$, and confirm the inequality with a graphing utility. [*Hint:* Show that the function $f(x) = \tan x - x$ is increasing on $[0, \pi/2)$.]

**43.** Use a graphing utility to make a conjecture about the relative sizes of $x$ and $\sin x$ for $x \geq 0$, and prove your conjecture.

**44.** Use a graphing utility to make a conjecture about the relative sizes of $1 - x^2/2$ and $\cos x$ for $x \geq 0$, and prove your conjecture. [*Hint:* Use the result of Exercise 43.]

**45.** (a) Show that $\ln(x + 1) \leq x$ if $x \geq 0$.
(b) Show that $\ln(x + 1) \geq x - \frac{1}{2}x^2$ if $x \geq 0$.
(c) Confirm the inequalities in parts (a) and (b) with a graphing utility.

**46.** (a) Show that $e^x \geq 1 + x$ if $x \geq 0$.
(b) Show that $e^x \geq 1 + x + \frac{1}{2}x^2$ if $x \geq 0$.
(c) Confirm the inequalities in parts (a) and (b) with a graphing utility.

**47–48** Use a graphing utility to generate the graphs of $f'$ and $f''$ over the stated interval; then use those graphs to estimate the $x$-coordinates of the inflection points of $f$, the intervals on which $f$ is concave up or down, and the intervals on which $f$ is increasing or decreasing. Check your estimates by graphing $f$.

**47.** $f(x) = x^4 - 24x^2 + 12x, \quad -5 \leq x \leq 5$

**48.** $f(x) = \dfrac{1}{1 + x^2}, \quad -5 \leq x \leq 5$

**C 49–50** Use a CAS to find $f''$ and to approximate the $x$-coordinates of the inflection points to six decimal places. Confirm that your answer is consistent with the graph of $f$.

**49.** $f(x) = \dfrac{10x - 3}{3x^2 - 5x + 8}$

**50.** $f(x) = \dfrac{x^3 - 8x + 7}{\sqrt{x^2 + 1}}$

**51.** Use Definition 4.1.1 to prove that $f(x) = x^2$ is increasing on $[0, +\infty)$.

**52.** Use Definition 4.1.1 to prove that $f(x) = 1/x$ is decreasing on $(0, +\infty)$.

**FOCUS ON CONCEPTS**

**53–54** Determine whether the statements are true or false. If a statement is false, find functions for which the statement fails to hold. ■

**53.** (a) If $f$ and $g$ are increasing on an interval, then so is $f + g$.
(b) If $f$ and $g$ are increasing on an interval, then so is $f \cdot g$.

**54.** (a) If $f$ and $g$ are concave up on an interval, then so is $f + g$.
(b) If $f$ and $g$ are concave up on an interval, then so is $f \cdot g$.

**55.** In each part, find functions $f$ and $g$ that are increasing on $(-\infty, +\infty)$ and for which $f - g$ has the stated property.
(a) $f - g$ is decreasing on $(-\infty, +\infty)$.
(b) $f - g$ is constant on $(-\infty, +\infty)$.
(c) $f - g$ is increasing on $(-\infty, +\infty)$.

**56.** In each part, find functions $f$ and $g$ that are positive and increasing on $(-\infty, +\infty)$ and for which $f/g$ has the stated property.
(a) $f/g$ is decreasing on $(-\infty, +\infty)$.
(b) $f/g$ is constant on $(-\infty, +\infty)$.
(c) $f/g$ is increasing on $(-\infty, +\infty)$.

**57.** (a) Prove that a general cubic polynomial

$$f(x) = ax^3 + bx^2 + cx + d \quad (a \neq 0)$$

has exactly one inflection point.
(b) Prove that if a cubic polynomial has three $x$-intercepts, then the inflection point occurs at the average value of the intercepts.
(c) Use the result in part (b) to find the inflection point of the cubic polynomial $f(x) = x^3 - 3x^2 + 2x$, and check your result by using $f''$ to determine where $f$ is concave up and concave down.

**58.** From Exercise 57, the polynomial $f(x) = x^3 + bx^2 + 1$ has one inflection point. Use a graphing utility to reach a conclusion about the effect of the constant $b$ on the location of the inflection point. Use $f''$ to explain what you have observed graphically.

**59.** Use Definition 4.1.1 to prove:
(a) If $f$ is increasing on the intervals $(a, c]$ and $[c, b)$, then $f$ is increasing on $(a, b)$.
(b) If $f$ is decreasing on the intervals $(a, c]$ and $[c, b)$, then $f$ is decreasing on $(a, b)$.

**60.** Use part (a) of Exercise 59 to show that $f(x) = x + \sin x$ is increasing on the interval $(-\infty, +\infty)$.

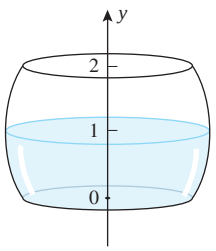
**61.** Use part (b) of Exercise 59 to show that $f(x) = \cos x - x$ is decreasing on the interval $(-\infty, +\infty)$.

**62.** Let $y = 1/(1 + x^2)$. Find the values of $x$ for which $y$ is increasing most rapidly or decreasing most rapidly.

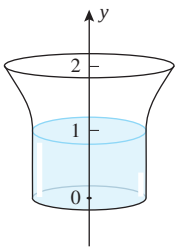
**FOCUS ON CONCEPTS**

**63–66** Suppose that water is flowing at a constant rate into the container shown. Make a rough sketch of the graph of the water level $y$ versus the time $t$. Make sure that your sketch conveys where the graph is concave up and concave down, and label the $y$-coordinates of the inflection points. ■

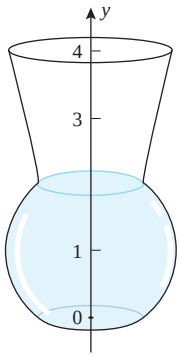
**63.**



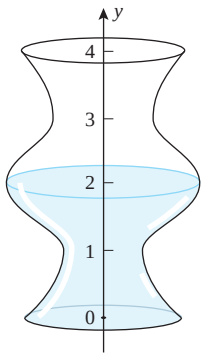
**64.**



**65.**



**66.**



**67.** Suppose that a population $y$ grows according to the logistic model given by Formula (1).
(a) At what rate is $y$ increasing at time $t = 0$?
(b) In words, describe how the rate of growth of $y$ varies with time.
(c) At what time is the population growing most rapidly?

**68.** Suppose that the number of individuals at time $t$ in a certain wildlife population is given by

$$N(t) = \frac{340}{1 + 9(0.77)^t}, \quad t \geq 0$$

where $t$ is in years. Use a graphing utility to estimate the time at which the size of the population is increasing most rapidly.

**69.** Suppose that the spread of a flu virus on a college campus is modeled by the function

$$y(t) = \frac{1000}{1 + 999e^{-0.9t}}$$

where $y(t)$ is the number of infected students at time $t$ (in days, starting with $t = 0$). Use a graphing utility to estimate the day on which the virus is spreading most rapidly.

**70.** The logistic growth model given in Formula (1) is equivalent to

$$ye^{kt} + Ay = Le^{kt}$$

where $y$ is the population at time $t$ ($t \geq 0$) and $A$, $k$, and $L$

are positive constants. Use implicit differentiation to verify that

$$\frac{dy}{dt} = \frac{k}{L}y(L - y)$$

$$\frac{d^2y}{dt^2} = \frac{k^2}{L^2}y(L - y)(L - 2y)$$

**71.** Assuming that $A$, $k$, and $L$ are positive constants, verify that the graph of $y = L/(1 + Ae^{-kt})$ has an inflection point at $\left(\frac{1}{k}\ln A, \frac{1}{2}L\right)$.

**72. Writing** An approaching storm causes the air temperature to fall. Make a statement that indicates there is an inflection point in the graph of temperature versus time. Explain how the existence of an inflection point follows from your statement.

**73. Writing** Explain what the sign analyses of $f'(x)$ and $f''(x)$ tell us about the graph of $y = f(x)$.

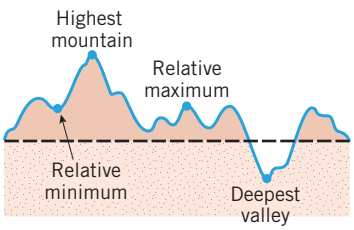
## ✔ QUICK CHECK ANSWERS 4.1

**1.** (a) $f(x_1) < f(x_2)$ (b) $f(x_1) > f(x_2)$ (c) increasing (d) $= 0$ (d) $(1, -1.1)$ **3.** (a) $(-\infty, +\infty)$ (b) $(4, 8)$ (c) $(-\infty, 4), (8, +\infty)$ **2.** (a) $-1, 3$ (b) $(-\infty, -1]$ and $[3, +\infty)$ (c) $(-\infty, 1)$ **4.** The graph is increasing and concave down.

# 4.2 ANALYSIS OF FUNCTIONS II: RELATIVE EXTREMA; GRAPHING POLYNOMIALS

*In this section we will develop methods for finding the high and low points on the graph of a function and we will discuss procedures for analyzing the graphs of polynomials.*

## RELATIVE MAXIMA AND MINIMA



▲ Figure 4.2.1

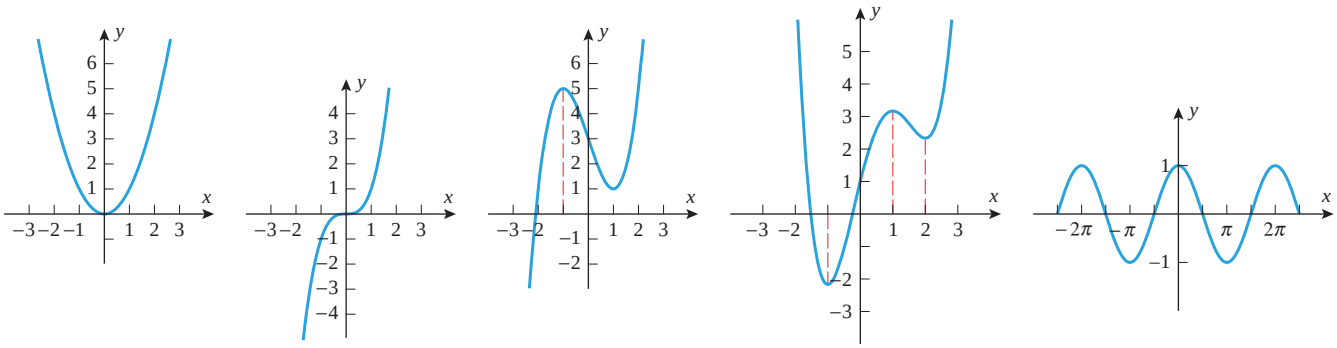
If we imagine the graph of a function $f$ to be a two-dimensional mountain range with hills and valleys, then the tops of the hills are called "relative maxima," and the bottoms of the valleys are called "relative minima" (Figure 4.2.1). The relative maxima are the high points in their *immediate vicinity*, and the relative minima are the low points. A relative maximum need not be the highest point in the entire mountain range, and a relative minimum need not be the lowest point—they are just high and low points *relative* to the nearby terrain. These ideas are captured in the following definition.

**4.2.1 DEFINITION** A function $f$ is said to have a ***relative maximum*** at $x_0$ if there is an open interval containing $x_0$ on which $f(x_0)$ is the largest value, that is, $f(x_0) \geq f(x)$ for all $x$ in the interval. Similarly, $f$ is said to have a ***relative minimum*** at $x_0$ if there is an open interval containing $x_0$ on which $f(x_0)$ is the smallest value, that is, $f(x_0) \leq f(x)$ for all $x$ in the interval. If $f$ has either a relative maximum or a relative minimum at $x_0$, then $f$ is said to have a ***relative extremum*** at $x_0$.

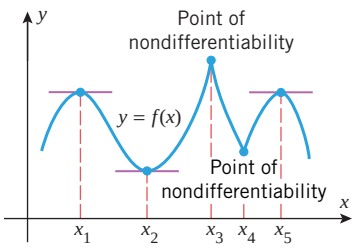
▶ **Example 1** We can see from Figure 4.2.2 that:

- $f(x) = x^2$ has a relative minimum at $x = 0$ but no relative maxima.
- $f(x) = x^3$ has no relative extrema.
- $f(x) = x^3 - 3x + 3$ has a relative maximum at $x = -1$ and a relative minimum at $x = 1$.
- $f(x) = \frac{1}{2}x^4 - \frac{4}{3}x^3 - x^2 + 4x + 1$ has relative minima at $x = -1$ and $x = 2$ and a relative maximum at $x = 1$.

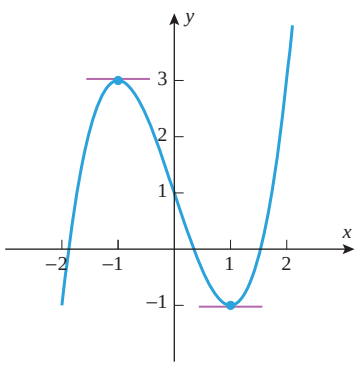
- $f(x) = \cos x$ has relative maxima at all even multiples of $\pi$ and relative minima at all odd multiples of $\pi$. ◄



▲ **Figure 4.2.2**



▲ **Figure 4.2.3** The points $x_1$, $x_2$, $x_3$, $x_4$, and $x_5$ are critical points. Of these, $x_1$, $x_2$, and $x_5$ are stationary points.



▲ **Figure 4.2.4**

What is the maximum number of critical points that a polynomial of degree $n$ can have? Why?

The relative extrema for the five functions in Example 1 occur at points where the graphs of the functions have horizontal tangent lines. Figure 4.2.3 illustrates that a relative extremum can also occur at a point where a function is not differentiable. In general, we define a ***critical point*** for a function $f$ to be a point in the domain of $f$ at which either the graph of $f$ has a horizontal tangent line or $f$ is not differentiable. To distinguish between the two types of critical points we call $x$ a ***stationary point*** of $f$ if $f'(x) = 0$. The following theorem, which is proved in Appendix J, states that the critical points for a function form a complete set of candidates for relative extrema on the interior of the domain of the function.

**4.2.2 THEOREM** *Suppose that $f$ is a function defined on an open interval containing the point $x_0$. If $f$ has a relative extremum at $x = x_0$, then $x = x_0$ is a critical point of $f$; that is, either $f'(x_0) = 0$ or $f$ is not differentiable at $x_0$.*

► **Example 2** Find all critical points of $f(x) = x^3 - 3x + 1$.

***Solution.*** The function $f$, being a polynomial, is differentiable everywhere, so its critical points are all stationary points. To find these points we must solve the equation $f'(x) = 0$. Since

$$f'(x) = 3x^2 - 3 = 3(x + 1)(x - 1)$$

we conclude that the critical points occur at $x = -1$ and $x = 1$. This is consistent with the graph of $f$ in Figure 4.2.4. ◄

► **Example 3** Find all critical points of $f(x) = 3x^{5/3} - 15x^{2/3}$.

***Solution.*** The function $f$ is continuous everywhere and its derivative is

$$f'(x) = 5x^{2/3} - 10x^{-1/3} = 5x^{-1/3}(x - 2) = \frac{5(x - 2)}{x^{1/3}}$$

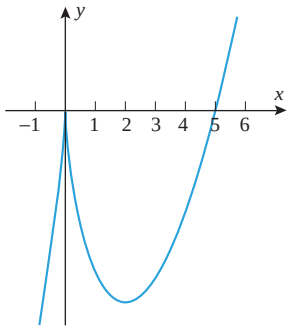
We see from this that $f'(x) = 0$ if $x = 2$ and $f'(x)$ is undefined if $x = 0$. Thus $x = 0$ and $x = 2$ are critical points and $x = 2$ is a stationary point. This is consistent with the graph of $f$ shown in Figure 4.2.5. ◀

**TECHNOLOGY MASTERY**

Your graphing utility may have trouble producing portions of the graph in Figure 4.2.5 because of the fractional exponents. If this is the case for you, graph the function

$$y = 3(|x|/x)|x|^{5/3} - 15|x|^{2/3}$$

which is equivalent to $f(x)$ for $x \neq 0$. Appendix A explores the method suggested here in more detail.



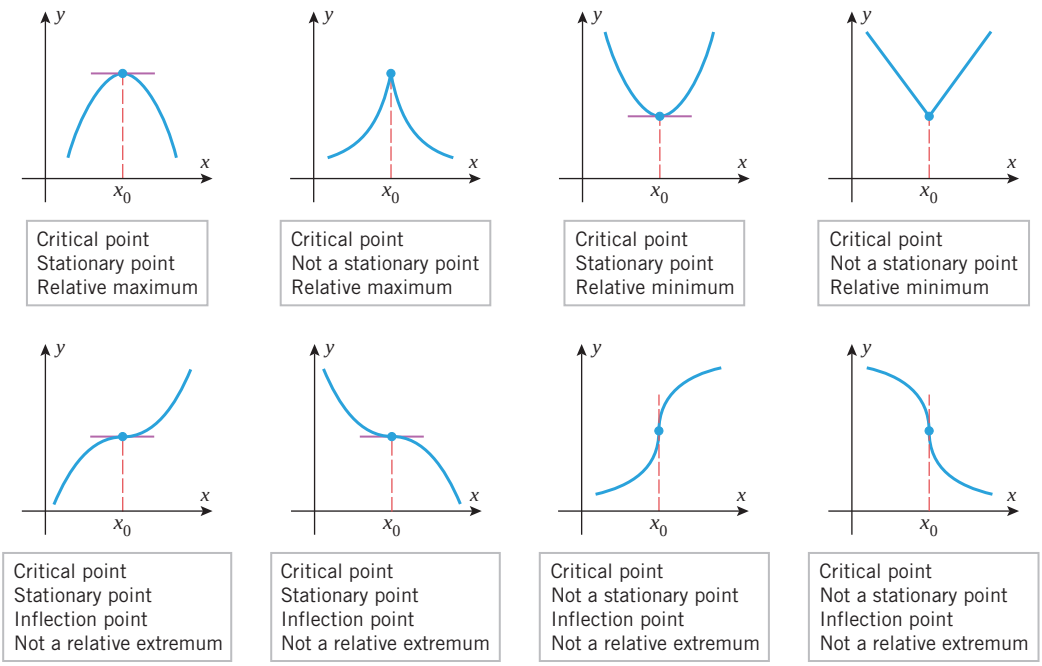
$y = 3x^{5/3} - 15x^{2/3}$

▲ Figure 4.2.5

## FIRST DERIVATIVE TEST

Theorem 4.2.2 asserts that the relative extrema must occur at critical points, but it does *not* say that a relative extremum occurs at *every* critical point. For example, for the eight critical points in Figure 4.2.6, relative extrema occur at each $x_0$ in the top row but not at any $x_0$ in the bottom row. Moreover, at the critical points in the first row the derivatives have opposite signs on the two sides of $x_0$, whereas at the critical points in the second row the signs of the derivatives are the same on both sides. This suggests:

*A function $f$ has a relative extremum at those critical points where $f'$ changes sign.*



▲ Figure 4.2.6

We can actually take this a step further. At the two relative maxima in Figure 4.2.6 the derivative is positive on the left side and negative on the right side, and at the two relative minima the derivative is negative on the left side and positive on the right side. All of this is summarized more precisely in the following theorem.

Informally stated, parts (*a*) and (*b*) of Theorem 4.2.3 tell us that for a continuous function, relative maxima occur at critical points where the derivative changes from + to − and relative minima where it changes from − to +.

**4.2.3 THEOREM** (*First Derivative Test*) *Suppose that $f$ is continuous at a critical point $x_0$.*

(*a*) *If $f'(x) > 0$ on an open interval extending left from $x_0$ and $f'(x) < 0$ on an open interval extending right from $x_0$, then $f$ has a relative maximum at $x_0$.*

(*b*) *If $f'(x) < 0$ on an open interval extending left from $x_0$ and $f'(x) > 0$ on an open interval extending right from $x_0$, then $f$ has a relative minimum at $x_0$.*

(*c*) *If $f'(x)$ has the same sign on an open interval extending left from $x_0$ as it does on an open interval extending right from $x_0$, then $f$ does not have a relative extremum at $x_0$.*

Use the first derivative test to confirm the behavior at $x_0$ of each graph in Figure 4.2.6.

**PROOF** We will prove part (*a*) and leave parts (*b*) and (*c*) as exercises. We are assuming that $f'(x) > 0$ on the interval $(a, x_0)$ and that $f'(x) < 0$ on the interval $(x_0, b)$, and we want to show that

$$f(x_0) \geq f(x)$$

for all $x$ in the interval $(a, b)$. However, the two hypotheses, together with Theorem 4.1.2 and its associated marginal note imply that $f$ is increasing on the interval $(a, x_0]$ and decreasing on the interval $[x_0, b)$. Thus, $f(x_0) \geq f(x)$ for all $x$ in $(a, b)$ with equality only at $x_0$. ■

▶ **Example 4** We showed in Example 3 that the function $f(x) = 3x^{5/3} - 15x^{2/3}$ has critical points at $x = 0$ and $x = 2$. Figure 4.2.5 suggests that $f$ has a relative maximum at $x = 0$ and a relative minimum at $x = 2$. Confirm this using the first derivative test.

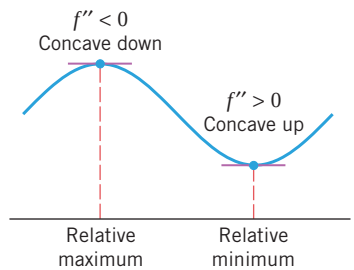
***Solution.*** We showed in Example 3 that

$$f'(x) = \frac{5(x-2)}{x^{1/3}}$$

A sign analysis of this derivative is shown in Table 4.2.1. The sign of $f'$ changes from + to − at $x = 0$, so there is a relative maximum at that point. The sign changes from − to + at $x = 2$, so there is a relative minimum at that point. ◀

**Table 4.2.1**

| INTERVAL | $5(x-2)/x^{1/3}$ | $f'(x)$ |
|---|---|---|
| $x < 0$ | (−)/(−) | + |
| $0 < x < 2$ | (−)/(+) | − |
| $x > 2$ | (+)/(+) | + |



▲ **Figure 4.2.7**

## SECOND DERIVATIVE TEST

There is another test for relative extrema that is based on the following geometric observation: A function $f$ has a relative maximum at a stationary point if the graph of $f$ is concave down on an open interval containing that point, and it has a relative minimum if it is concave up (Figure 4.2.7).

**4.2.4 THEOREM** (*Second Derivative Test*) *Suppose that $f$ is twice differentiable at the point $x_0$.*

(*a*) *If $f'(x_0) = 0$ and $f''(x_0) > 0$, then $f$ has a relative minimum at $x_0$.*

(*b*) *If $f'(x_0) = 0$ and $f''(x_0) < 0$, then $f$ has a relative maximum at $x_0$.*

(*c*) *If $f'(x_0) = 0$ and $f''(x_0) = 0$, then the test is inconclusive; that is, $f$ may have a relative maximum, a relative minimum, or neither at $x_0$.*

The second derivative test is often easier to apply than the first derivative test. However, the first derivative test can be used at any critical point of a continuous function, while the second derivative test applies only at stationary points where the second derivative exists.

We will prove parts $(a)$ and $(c)$ and leave part $(b)$ as an exercise.

**PROOF $(a)$** We are given that $f'(x_0) = 0$ and $f''(x_0) > 0$, and we want to show that $f$ has a relative minimum at $x_0$. Expressing $f''(x_0)$ as a limit and using the two given conditions we obtain

$$f''(x_0) = \lim_{x \to x_0} \frac{f'(x) - f'(x_0)}{x - x_0} = \lim_{x \to x_0} \frac{f'(x)}{x - x_0} > 0$$

This implies that for $x$ sufficiently close to but different from $x_0$ we have

$$\frac{f'(x)}{x - x_0} > 0 \tag{1}$$

Thus, there is an open interval extending left from $x_0$ and an open interval extending right from $x_0$ on which (1) holds. On the open interval extending left the denominator in (1) is negative, so $f'(x) < 0$, and on the open interval extending right the denominator is positive, so $f'(x) > 0$. It now follows from part $(b)$ of the first derivative test (Theorem 4.2.3) that $f$ has a relative minimum at $x_0$.

**PROOF $(c)$** To prove this part of the theorem we need only provide functions for which $f'(x_0) = 0$ and $f''(x_0) = 0$ at some point $x_0$, but with one having a relative minimum at $x_0$, one having a relative maximum at $x_0$, and one having neither at $x_0$. We leave it as an exercise for you to show that three such functions are $f(x) = x^4$ (relative minimum at $x = 0$), $f(x) = -x^4$ (relative maximum at $x = 0$), and $f(x) = x^3$ (neither a relative maximum nor a relative minimum at $x_0$). ■

▶ **Example 5** Find the relative extrema of $f(x) = 3x^5 - 5x^3$.

***Solution.*** We have

$$f'(x) = 15x^4 - 15x^2 = 15x^2(x^2 - 1) = 15x^2(x + 1)(x - 1)$$
$$f''(x) = 60x^3 - 30x = 30x(2x^2 - 1)$$

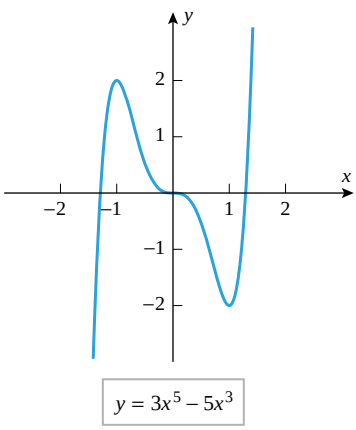
Solving $f'(x) = 0$ yields the stationary points $x = 0$, $x = -1$, and $x = 1$. As shown in the following table, we can conclude from the second derivative test that $f$ has a relative maximum at $x = -1$ and a relative minimum at $x = 1$.

| STATIONARY POINT | $30x(2x^2 - 1)$ | $f''(x)$ | SECOND DERIVATIVE TEST |
|---|---|---|---|
| $x = -1$ | $-30$ | $-$ | $f$ has a relative maximum |
| $x = 0$ | 0 | 0 | Inconclusive |
| $x = 1$ | 30 | $+$ | $f$ has a relative minimum |

The test is inconclusive at $x = 0$, so we will try the first derivative test at that point. A sign analysis of $f'$ is given in the following table:

| INTERVAL | $15x^2(x + 1)(x - 1)$ | $f'(x)$ |
|---|---|---|
| $-1 < x < 0$ | $(+)(+)(-)$ | $-$ |
| $0 < x < 1$ | $(+)(+)(-)$ | $-$ |

Since there is no sign change in $f'$ at $x = 0$, there is neither a relative maximum nor a relative minimum at that point. All of this is consistent with the graph of $f$ shown in Figure 4.2.8. ◀



▲ Figure 4.2.8

## GEOMETRIC IMPLICATIONS OF MULTIPLICITY

Our final goal in this section is to outline a general procedure that can be used to analyze and graph polynomials. To do so, it will be helpful to understand how the graph of a polynomial behaves in the vicinity of its roots. For example, it would be nice to know what property of the polynomial in Example 5 produced the inflection point and horizontal tangent at the root $x = 0$.

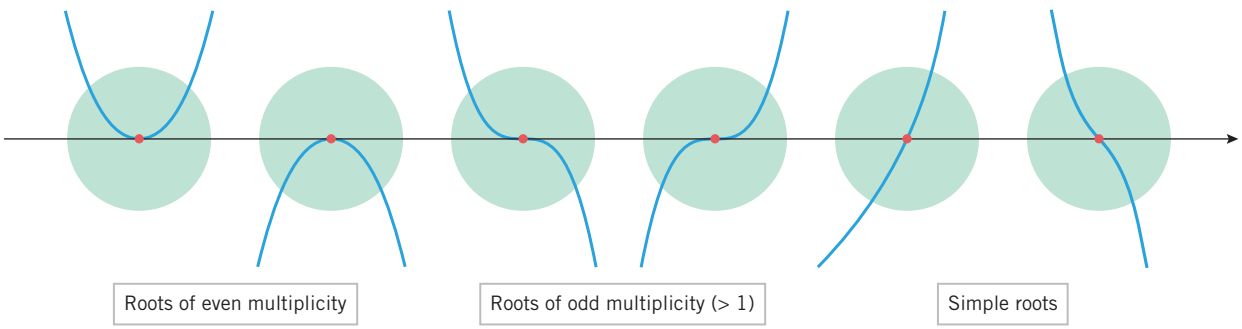
Recall that a root $x = r$ of a polynomial $p(x)$ has ***multiplicity m*** if $(x - r)^m$ divides $p(x)$ but $(x - r)^{m+1}$ does not. A root of multiplicity 1 is called a ***simple root***. Figure 4.2.9 and the following theorem show that the behavior of a polynomial in the vicinity of a real root is determined by the multiplicity of that root (we omit the proof ).

**4.2.5 THE GEOMETRIC IMPLICATIONS OF MULTIPLICITY** *Suppose that $p(x)$ is a polynomial with a root of multiplicity $m$ at $x = r$.*

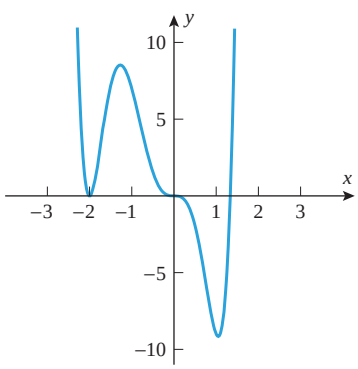
(*a*) *If $m$ is even, then the graph of $y = p(x)$ is tangent to the $x$-axis at $x = r$, does not cross the $x$-axis there, and does not have an inflection point there.*

(*b*) *If $m$ is odd and greater than 1, then the graph is tangent to the $x$-axis at $x = r$, crosses the $x$-axis there, and also has an inflection point there.*

(*c*) *If $m = 1$ (so that the root is simple), then the graph is not tangent to the $x$-axis at $x = r$, crosses the $x$-axis there, and may or may not have an inflection point there.*



▲ **Figure 4.2.9**



▲ **Figure 4.2.10**

**Example 6** Make a conjecture about the behavior of the graph of

$$y = x^3(3x - 4)(x + 2)^2$$

in the vicinity of its $x$-intercepts, and test your conjecture by generating the graph.

***Solution.*** The $x$-intercepts occur at $x = 0$, $x = \frac{4}{3}$, and $x = -2$. The root $x = 0$ has multiplicity 3, which is odd, so at that point the graph should be tangent to the $x$-axis, cross the $x$-axis, and have an inflection point there. The root $x = -2$ has multiplicity 2, which is even, so the graph should be tangent to but not cross the $x$-axis there. The root $x = \frac{4}{3}$ is simple, so at that point the curve should cross the $x$-axis without being tangent to it. All of this is consistent with the graph in Figure 4.2.10. ◄

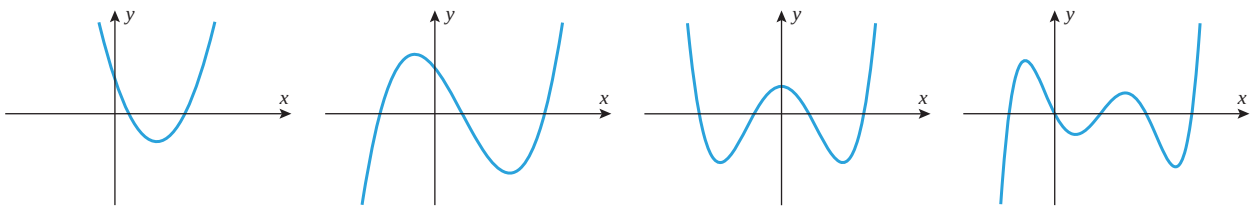
## ANALYSIS OF POLYNOMIALS

Historically, the term "curve sketching" meant using calculus to help draw the graph of a function by hand—the graph was the goal. Since graphs can now be produced with great precision using calculators and computers, the purpose of curve sketching has changed. Today, we typically start with a graph produced by a calculator or computer, then use curve sketching to identify important features of the graph that the calculator or computer might have missed. Thus, the goal of curve sketching is no longer the graph itself, but rather the information it reveals about the function.

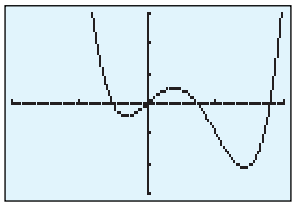
Polynomials are among the simplest functions to graph and analyze. Their significant features are symmetry, intercepts, relative extrema, inflection points, and the behavior as $x \to +\infty$ and as $x \to -\infty$. Figure 4.2.11 shows the graphs of four polynomials in $x$. The graphs in Figure 4.2.11 have properties that are common to all polynomials:

- The natural domain of a polynomial is $(-\infty, +\infty)$.
- Polynomials are continuous everywhere.
- Polynomials are differentiable everywhere, so their graphs have no corners or vertical tangent lines.
- The graph of a nonconstant polynomial eventually increases or decreases without bound as $x \to +\infty$ and as $x \to -\infty$. This is because the limit of a nonconstant polynomial as $x \to +\infty$ or as $x \to -\infty$ is $\pm\infty$, depending on the sign of the term of highest degree and whether the polynomial has even or odd degree [see Formulas (17) and (18) of Section 1.3 and the related discussion].
- The graph of a polynomial of degree $n\ (> 2)$ has at most $n$ $x$-intercepts, at most $n - 1$ relative extrema, and at most $n - 2$ inflection points. This is because the $x$-intercepts, relative extrema, and inflection points of a polynomial $p(x)$ are among the real solutions of the equations $p(x) = 0$, $p'(x) = 0$, and $p''(x) = 0$, and the polynomials in these equations have degree $n$, $n - 1$, and $n - 2$, respectively. Thus, for example, the graph of a quadratic polynomial has at most two $x$-intercepts, one relative extremum, and no inflection points; and the graph of a cubic polynomial has at most three $x$-intercepts, two relative extrema, and one inflection point.

For each of the graphs in Figure 4.2.11, count the number of $x$-intercepts, relative extrema, and inflection points, and confirm that your count is consistent with the degree of the polynomial.



▲ **Figure 4.2.11**



$[-2, 2] \times [-3, 3]$

$y = 3x^4 - 6x^3 + 2x$

▲ **Figure 4.2.12**

▶ **Example 7** Figure 4.2.12 shows the graph of

$$y = 3x^4 - 6x^3 + 2x$$

produced on a graphing calculator. Confirm that the graph is not missing any significant features.

***Solution.*** We can be confident that the graph shows all significant features of the polynomial because the polynomial has degree 4 and we can account for four roots, three relative extrema, and two inflection points. Moreover, the graph suggests the correct behavior as

$x \to +\infty$ and as $x \to -\infty$, since

$$\lim_{x \to +\infty} (3x^4 - 6x^3 + 2x) = \lim_{x \to +\infty} 3x^4 = +\infty$$

$$\lim_{x \to -\infty} (3x^4 - 6x^3 + 2x) = \lim_{x \to -\infty} 3x^4 = +\infty \quad \blacktriangleleft$$

**▶ Example 8** Sketch the graph of the equation

$$y = x^3 - 3x + 2$$

and identify the locations of the intercepts, relative extrema, and inflection points.

***Solution.*** The following analysis will produce the information needed to sketch the graph:

A review of polynomial factoring is given in Appendix C.

- *x-intercepts:* Factoring the polynomial yields
$$x^3 - 3x + 2 = (x + 2)(x - 1)^2$$
which tells us that the $x$-intercepts are $x = -2$ and $x = 1$.
- *y-intercept:* Setting $x = 0$ yields $y = 2$.
- *End behavior:* We have
$$\lim_{x \to +\infty} (x^3 - 3x + 2) = \lim_{x \to +\infty} x^3 = +\infty$$
$$\lim_{x \to -\infty} (x^3 - 3x + 2) = \lim_{x \to -\infty} x^3 = -\infty$$
so the graph increases without bound as $x \to +\infty$ and decreases without bound as $x \to -\infty$.
- *Derivatives:*
$$\frac{dy}{dx} = 3x^2 - 3 = 3(x - 1)(x + 1)$$
$$\frac{d^2y}{dx^2} = 6x$$
- *Increase, decrease, relative extrema, inflection points:* Figure 4.2.13 gives a sign analysis of the first and second derivatives and indicates its geometric significance. There are stationary points at $x = -1$ and $x = 1$. Since the sign of $dy/dx$ changes from $+$ to $-$ at $x = -1$, there is a relative maximum there, and since it changes from $-$ to $+$ at $x = 1$, there is a relative minimum there. The sign of $d^2y/dx^2$ changes from $-$ to $+$ at $x = 0$, so there is an inflection point there.
- *Final sketch:* Figure 4.2.14 shows the final sketch with the coordinates of the intercepts, relative extrema, and inflection point labeled. $\blacktriangleleft$

## ✔ QUICK CHECK EXERCISES 4.2 (See page 254 for answers.)

1. A function $f$ has a relative maximum at $x_0$ if there is an open interval containing $x_0$ on which $f(x)$ is _____ $f(x_0)$ for every $x$ in the interval.
2. Suppose that $f$ is defined everywhere and $x = 2, 3, 5, 7$ are critical points for $f$. If $f'(x)$ is positive on the intervals $(-\infty, 2)$ and $(5, 7)$, and if $f'(x)$ is negative on the intervals $(2, 3)$, $(3, 5)$, and $(7, +\infty)$, then $f$ has relative maxima at $x =$ _____ and $f$ has relative minima at $x =$ _____.
3. Suppose that $f$ is defined everywhere and $x = -2$ and $x = 1$ are critical points for $f$. If $f''(x) = 2x + 1$, then $f$ has a relative _____ at $x = -2$ and $f$ has a relative _____ at $x = 1$.
4. Let $f(x) = (x^2 - 4)^2$. Then $f'(x) = 4x(x^2 - 4)$ and $f''(x) = 4(3x^2 - 4)$. Identify the locations of the (a) relative maxima, (b) relative minima, and (c) inflection points on the graph of $f$.

## EXERCISE SET 4.2 Graphing Utility C CAS

### FOCUS ON CONCEPTS

1. In each part, sketch the graph of a continuous function $f$ with the stated properties.
   (a) $f$ is concave up on the interval $(-\infty, +\infty)$ and has exactly one relative extremum.
   (b) $f$ is concave up on the interval $(-\infty, +\infty)$ and has no relative extrema.
   (c) The function $f$ has exactly two relative extrema on the interval $(-\infty, +\infty)$, and $f(x) \to +\infty$ as $x \to +\infty$.
   (d) The function $f$ has exactly two relative extrema on the interval $(-\infty, +\infty)$, and $f(x) \to -\infty$ as $x \to +\infty$.
2. In each part, sketch the graph of a continuous function $f$ with the stated properties.
   (a) $f$ has exactly one relative extremum on $(-\infty, +\infty)$, and $f(x) \to 0$ as $x \to +\infty$ and as $x \to -\infty$.
   (b) $f$ has exactly two relative extrema on $(-\infty, +\infty)$, and $f(x) \to 0$ as $x \to +\infty$ and as $x \to -\infty$.
   (c) $f$ has exactly one inflection point and one relative extremum on $(-\infty, +\infty)$.
   (d) $f$ has infinitely many relative extrema, and $f(x) \to 0$ as $x \to +\infty$ and as $x \to -\infty$.
3. (a) Use both the first and second derivative tests to show that $f(x) = 3x^2 - 6x + 1$ has a relative minimum at $x = 1$.
   (b) Use both the first and second derivative tests to show that $f(x) = x^3 - 3x + 3$ has a relative minimum at $x = 1$ and a relative maximum at $x = -1$.
4. (a) Use both the first and second derivative tests to show that $f(x) = \sin^2 x$ has a relative minimum at $x = 0$.
   (b) Use both the first and second derivative tests to show that $g(x) = \tan^2 x$ has a relative minimum at $x = 0$.
   (c) Give an informal verbal argument to explain without calculus why the functions in parts (a) and (b) have relative minima at $x = 0$.
5. (a) Show that both of the functions $f(x) = (x - 1)^4$ and $g(x) = x^3 - 3x^2 + 3x - 2$ have stationary points at $x = 1$.
   (b) What does the second derivative test tell you about the nature of these stationary points?
   (c) What does the first derivative test tell you about the nature of these stationary points?
6. (a) Show that $f(x) = 1 - x^5$ and $g(x) = 3x^4 - 8x^3$ both have stationary points at $x = 0$.
   (b) What does the second derivative test tell you about the nature of these stationary points?
   (c) What does the first derivative test tell you about the nature of these stationary points?

**7–14** Locate the critical points and identify which critical points are stationary points. ■

7. $f(x) = 4x^4 - 16x^2 + 17$
8. $f(x) = 3x^4 + 12x$
9. $f(x) = \dfrac{x + 1}{x^2 + 3}$
10. $f(x) = \dfrac{x^2}{x^3 + 8}$
11. $f(x) = \sqrt[3]{x^2 - 25}$
12. $f(x) = x^2(x - 1)^{2/3}$
13. $f(x) = |\sin x|$
14. $f(x) = \sin|x|$

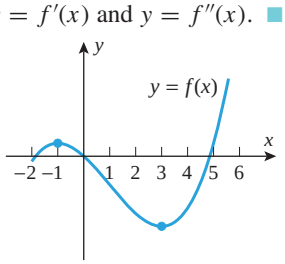
**15–18 True–False** Assume that $f$ is continuous everywhere. Determine whether the statement is true or false. Explain your answer. ■

15. If $f$ has a relative maximum at $x = 1$, then $f(1) \geq f(2)$.
16. If $f$ has a relative maximum at $x = 1$, then $x = 1$ is a critical point for $f$.
17. If $f''(x) > 0$, then $f$ has a relative minimum at $x = 1$.
18. If $p(x)$ is a polynomial such that $p'(x)$ has a simple root at $x = 1$, then $p$ has a relative extremum at $x = 1$.

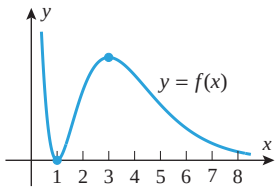
### FOCUS ON CONCEPTS

**19–20** The graph of a function $f(x)$ is given. Sketch graphs of $y = f'(x)$ and $y = f''(x)$. ■

19.

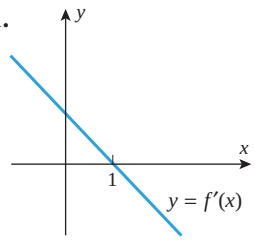


**20.**

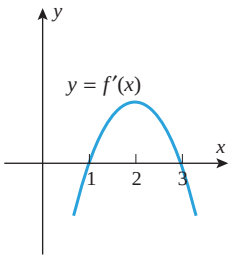


**21–24** Use the graph of $f'$ shown in the figure to estimate all values of $x$ at which $f$ has (a) relative minima, (b) relative maxima, and (c) inflection points. (d) Draw a rough sketch of the graph of a function $f$ with the given derivative.

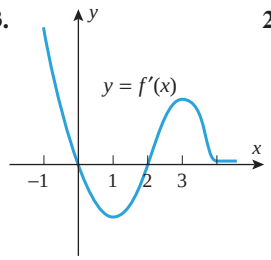
**21.**



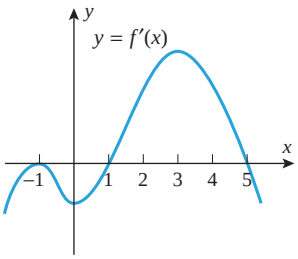
**22.**



**23.**



**24.**



**25–32** Use the given derivative to find all critical points of $f$, and at each critical point determine whether a relative maximum, relative minimum, or neither occurs. Assume in each case that $f$ is continuous everywhere.

**25.** $f'(x) = x^2(x^3 - 5)$

**26.** $f'(x) = 4x^3 - 9x$

**27.** $f'(x) = \dfrac{2 - 3x}{\sqrt[3]{x + 2}}$

**28.** $f'(x) = \dfrac{x^2 - 7}{\sqrt[3]{x^2 + 4}}$

**29.** $f'(x) = xe^{1-x^2}$

**30.** $f'(x) = x^4(e^x - 3)$

**31.** $f'(x) = \ln\left(\dfrac{2}{1 + x^2}\right)$

**32.** $f'(x) = e^{2x} - 5e^x + 6$

**33–36** Find the relative extrema using both first and second derivative tests.

**33.** $f(x) = 1 + 8x - 3x^2$

**34.** $f(x) = x^4 - 12x^3$

**35.** $f(x) = \sin 2x, \quad 0 < x < \pi$

**36.** $f(x) = (x - 3)e^x$

**37–50** Use any method to find the relative extrema of the function $f$.

**37.** $f(x) = x^4 - 4x^3 + 4x^2$

**38.** $f(x) = x(x - 4)^3$

**39.** $f(x) = x^3(x + 1)^2$

**40.** $f(x) = x^2(x + 1)^3$

**41.** $f(x) = 2x + 3x^{2/3}$

**42.** $f(x) = 2x + 3x^{1/3}$

**43.** $f(x) = \dfrac{x + 3}{x - 2}$

**44.** $f(x) = \dfrac{x^2}{x^4 + 16}$

**45.** $f(x) = \ln(2 + x^2)$

**46.** $f(x) = \ln|2 + x^3|$

**47.** $f(x) = e^{2x} - e^x$

**48.** $f(x) = (xe^x)^2$

**49.** $f(x) = |3x - x^2|$

**50.** $f(x) = |1 + \sqrt[3]{x}|$

**51–60** Give a graph of the polynomial and label the coordinates of the intercepts, stationary points, and inflection points. Check your work with a graphing utility.

**51.** $p(x) = x^2 - 3x - 4$

**52.** $p(x) = 1 + 8x - x^2$

**53.** $p(x) = 2x^3 - 3x^2 - 36x + 5$

**54.** $p(x) = 2 - x + 2x^2 - x^3$

**55.** $p(x) = (x + 1)^2(2x - x^2)$

**56.** $p(x) = x^4 - 6x^2 + 5$

**57.** $p(x) = x^4 - 2x^3 + 2x - 1$

**58.** $p(x) = 4x^3 - 9x^4$

**59.** $p(x) = x(x^2 - 1)^2$

**60.** $p(x) = x(x^2 - 1)^3$

**61.** In each part: (i) Make a conjecture about the behavior of the graph in the vicinity of its $x$-intercepts. (ii) Make a rough sketch of the graph based on your conjecture and the limits of the polynomial as $x \to +\infty$ and as $x \to -\infty$. (iii) Compare your sketch to the graph generated with a graphing utility.
(a) $y = x(x - 1)(x + 1)$ (b) $y = x^2(x - 1)^2(x + 1)^2$
(c) $y = x^2(x - 1)^2(x + 1)^3$ (d) $y = x(x - 1)^5(x + 1)^4$

**62.** Sketch the graph of $y = (x - a)^m(x - b)^n$ for the stated values of $m$ and $n$, assuming that $a < b$ (six graphs in total).
(a) $m = 1,\ n = 1, 2, 3$ (b) $m = 2,\ n = 2, 3$
(c) $m = 3,\ n = 3$

**63–66** Find the relative extrema in the interval $0 < x < 2\pi$, and confirm that your results are consistent with the graph of $f$ generated with a graphing utility.

**63.** $f(x) = |\sin 2x|$

**64.** $f(x) = \sqrt{3}x + 2\sin x$

**65.** $f(x) = \cos^2 x$

**66.** $f(x) = \dfrac{\sin x}{2 - \cos x}$

**67–70** Use a graphing utility to make a conjecture about the relative extrema of $f$, and then check your conjecture using either the first or second derivative test.

**67.** $f(x) = x \ln x$

**68.** $f(x) = \dfrac{2}{e^x + e^{-x}}$

**69.** $f(x) = x^2e^{-2x}$

**70.** $f(x) = 10 \ln x - x$

**71–72** Use a graphing utility to generate the graphs of $f'$ and $f''$ over the stated interval, and then use those graphs to estimate the $x$-coordinates of the relative extrema of $f$. Check that your estimates are consistent with the graph of $f$.

**71.** $f(x) = x^4 - 24x^2 + 12x, \quad -5 \le x \le 5$

**72.** $f(x) = \sin\frac{1}{2}x \cos x, \quad -\pi/2 \le x \le \pi/2$

**C** **73–76** Use a CAS to graph $f'$ and $f''$, and then use those graphs to estimate the $x$-coordinates of the relative extrema of $f$. Check that your estimates are consistent with the graph of $f$.

**73.** $f(x) = \dfrac{10x^3 - 3}{3x^2 - 5x + 8}$

**74.** $f(x) = \dfrac{\tan^{-1}(x^2 - x)}{x^2 + 4}$

**75.** $f(x) = \sqrt{x^4 + \cos^2 x}$ **76.** $f(x) = x^2(e^{2x} - e^x)$

**77.** In each part, find $k$ so that $f$ has a relative extremum at the point where $x = 3$.

(a) $f(x) = x^2 + \dfrac{k}{x}$ (b) $f(x) = \dfrac{x}{x^2 + k}$

C **78.** (a) Use a CAS to graph the function

$$f(x) = \frac{x^4 + 1}{x^2 + 1}$$

and use the graph to estimate the $x$-coordinates of the relative extrema.

(b) Find the exact $x$-coordinates by using the CAS to solve the equation $f'(x) = 0$.

**79.** Functions similar to

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$$

arise in a wide variety of statistical problems.

(a) Use the first derivative test to show that $f$ has a relative maximum at $x = 0$, and confirm this by using a graphing utility to graph $f$.

(b) Sketch the graph of

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{-(x-\mu)^2/2}$$

where $\mu$ is a constant, and label the coordinates of the relative extrema.

**80.** Functions of the form

$$f(x) = \frac{x^n e^{-x}}{n!}, \quad x > 0$$

where $n$ is a positive integer, arise in the statistical study of traffic flow.

(a) Use a graphing utility to generate the graph of $f$ for $n = 2, 3, 4$, and 5, and make a conjecture about the number and locations of the relative extrema of $f$.

(b) Confirm your conjecture using the first derivative test.

**81.** Let $h$ and $g$ have relative maxima at $x_0$. Prove or disprove:

(a) $h + g$ has a relative maximum at $x_0$

(b) $h - g$ has a relative maximum at $x_0$.

**82.** Sketch some curves that show that the three parts of the first derivative test (Theorem 4.2.3) can be false without the assumption that $f$ is continuous at $x_0$.

**83.** **Writing** Discuss the relative advantages or disadvantages of using the first derivative test versus using the second derivative test to classify candidates for relative extrema on the interior of the domain of a function. Include specific examples to illustrate your points.

**84.** **Writing** If $p(x)$ is a polynomial, discuss the usefulness of knowing zeros for $p$, $p'$, and $p''$ when determining information about the graph of $p$.

**1.** less than or equal to **2.** 2, 7; 5 **3.** maximum; minimum **4.** (a) (0, 16) (b) $(-2, 0)$ and $(2, 0)$ (c) $(-2/\sqrt{3}, 64/9)$ and $(2/\sqrt{3}, 64/9)$

# 4.3 ANALYSIS OF FUNCTIONS III: RATIONAL FUNCTIONS, CUSPS, AND VERTICAL TANGENTS

*In this section we will discuss procedures for graphing rational functions and other kinds of curves. We will also discuss the interplay between calculus and technology in curve sketching.*

## PROPERTIES OF GRAPHS

In many problems, the properties of interest in the graph of a function are:

- symmetries
- $x$-intercepts
- relative extrema
- intervals of increase and decrease
- asymptotes
- periodicity
- $y$-intercepts
- concavity
- inflection points
- behavior as $x \to +\infty$ or as $x \to -\infty$

Some of these properties may not be relevant in certain cases; for example, asymptotes are characteristic of rational functions but not of polynomials, and periodicity is characteristic of

trigonometric functions but not of polynomial or rational functions. Thus, when analyzing the graph of a function $f$, it helps to know something about the general properties of the family to which it belongs.

In a given problem you will usually have a definite objective for your analysis of a graph. For example, you may be interested in showing all of the important characteristics of the function, you may only be interested in the behavior of the graph as $x \to +\infty$ or as $x \to -\infty$, or you may be interested in some specific feature such as a particular inflection point. Thus, your objectives in the problem will dictate those characteristics on which you want to focus.

## GRAPHING RATIONAL FUNCTIONS

Recall that a rational function is a function of the form $f(x) = P(x)/Q(x)$ in which $P(x)$ and $Q(x)$ are polynomials. Graphs of rational functions are more complicated than those of polynomials because of the possibility of asymptotes and discontinuities (see Figure 0.3.11, for example). If $P(x)$ and $Q(x)$ have no common factors, then the information obtained in the following steps will usually be sufficient to obtain an accurate sketch of the graph of a rational function.

***Graphing a Rational Function $f(x) = P(x)/Q(x)$ if $P(x)$ and $Q(x)$ have no Common Factors***

**Step 1. (symmetries).** Determine whether there is symmetry about the $y$-axis or the origin.

**Step 2. ($x$- and $y$-intercepts).** Find the $x$- and $y$-intercepts.

**Step 3. (vertical asymptotes).** Find the values of $x$ for which $Q(x) = 0$. The graph has a vertical asymptote at each such value.

**Step 4. (sign of $f(x)$).** The only places where $f(x)$ can change sign are at the $x$-intercepts or vertical asymptotes. Mark the points on the $x$-axis at which these occur and calculate a sample value of $f(x)$ in each of the open intervals determined by these points. This will tell you whether $f(x)$ is positive or negative over that interval.

**Step 5. (end behavior).** Determine the end behavior of the graph by computing the limits of $f(x)$ as $x \to +\infty$ and as $x \to -\infty$. If either limit has a finite value $L$, then the line $y = L$ is a horizontal asymptote.

**Step 6. (derivatives).** Find $f'(x)$ and $f''(x)$.

**Step 7. (conclusions and graph).** Analyze the sign changes of $f'(x)$ and $f''(x)$ to determine the intervals where $f(x)$ is increasing, decreasing, concave up, and concave down. Determine the locations of all stationary points, relative extrema, and inflection points. Use the sign analysis of $f(x)$ to determine the behavior of the graph in the vicinity of the vertical asymptotes. Sketch a graph of $f$ that exhibits these conclusions.

▶ **Example 1** Sketch a graph of the equation

$$y = \frac{2x^2 - 8}{x^2 - 16}$$

and identify the locations of the intercepts, relative extrema, inflection points, and asymptotes.

***Solution.*** The numerator and denominator have no common factors, so we will use the procedure just outlined.

- *Symmetries:* Replacing $x$ by $-x$ does not change the equation, so the graph is symmetric about the $y$-axis.
- *$x$- and $y$-intercepts:* Setting $y = 0$ yields the $x$-intercepts $x = -2$ and $x = 2$. Setting $x = 0$ yields the $y$-intercept $y = \frac{1}{2}$.
- *Vertical asymptotes:* We observed above that the numerator and denominator of $y$ have no common factors, so the graph has vertical asymptotes at the points where the denominator of $y$ is zero, namely, at $x = -4$ and $x = 4$.
- *Sign of $y$:* The set of points where $x$-intercepts or vertical asymptotes occur is $\{-4, -2, 2, 4\}$. These points divide the $x$-axis into the open intervals

$$(-\infty, -4), \quad (-4, -2), \quad (-2, 2), \quad (2, 4), \quad (4, +\infty)$$

We can find the sign of $y$ on each interval by choosing an arbitrary test point in the interval and evaluating $y = f(x)$ at the test point (Table 4.3.1). This analysis is summarized on the first line of Figure 4.3.1*a*.

**Table 4.3.1**

SIGN ANALYSIS OF $y = \dfrac{2x^2 - 8}{x^2 - 16}$

| INTERVAL | TEST POINT | VALUE OF $y$ | SIGN OF $y$ |
|---|---|---|---|
| $(-\infty, -4)$ | $-5$ | 14/3 | + |
| $(-4, -2)$ | $-3$ | $-10/7$ | − |
| $(-2, 2)$ | 0 | 1/2 | + |
| $(2, 4)$ | 3 | $-10/7$ | − |
| $(4, +\infty)$ | 5 | 14/3 | + |

- *End behavior:* The limits

$$\lim_{x \to +\infty} \frac{2x^2 - 8}{x^2 - 16} = \lim_{x \to +\infty} \frac{2 - (8/x^2)}{1 - (16/x^2)} = 2$$
$$\lim_{x \to -\infty} \frac{2x^2 - 8}{x^2 - 16} = \lim_{x \to -\infty} \frac{2 - (8/x^2)}{1 - (16/x^2)} = 2$$

yield the horizontal asymptote $y = 2$.

- *Derivatives:*

$$\frac{dy}{dx} = \frac{(x^2 - 16)(4x) - (2x^2 - 8)(2x)}{(x^2 - 16)^2} = -\frac{48x}{(x^2 - 16)^2}$$
$$\frac{d^2y}{dx^2} = \frac{48(16 + 3x^2)}{(x^2 - 16)^3} \quad \text{(verify)}$$

*Conclusions and graph:*

- The sign analysis of $y$ in Figure 4.3.1*a* reveals the behavior of the graph in the vicinity of the vertical asymptotes: The graph increases without bound as $x \to -4^-$ and decreases without bound as $x \to -4^+$; and the graph decreases without bound as $x \to 4^-$ and increases without bound as $x \to 4^+$ (Figure 4.3.1*b*).
- The sign analysis of $dy/dx$ in Figure 4.3.1*a* shows that the graph is increasing to the left of $x = 0$ and is decreasing to the right of $x = 0$. Thus, there is a relative maximum at the stationary point $x = 0$. There are no relative minima.
- The sign analysis of $d^2y/dx^2$ in Figure 4.3.1*a* shows that the graph is concave up to the left of $x = -4$, is concave down between $x = -4$ and $x = 4$, and is concave up to the right of $x = 4$. There are no inflection points.

The graph is shown in Figure 4.3.1*c*. ◀

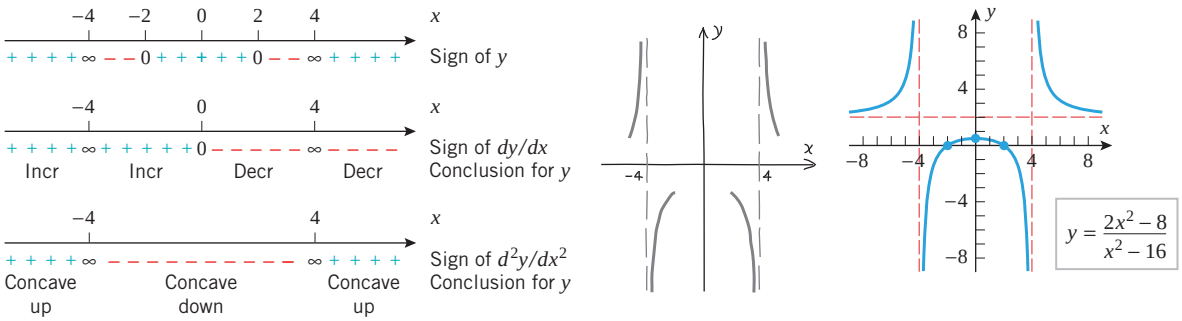
The procedure we stated for graphing a rational function $P(x)/Q(x)$ applies only if the polynomials $P(x)$ and $Q(x)$ have no common factors. How would you find the graph if those polynomials have common factors?

▶ **Example 2** Sketch a graph of

$$y = \frac{x^2 - 1}{x^3}$$

and identify the locations of all asymptotes, intercepts, relative extrema, and inflection points.

***Solution.*** The numerator and denominator have no common factors, so we will use the procedure outlined previously.



▲ **Figure 4.3.1**

**Table 4.3.2**

SIGN ANALYSIS OF $y = \dfrac{x^2-1}{x^3}$

| INTERVAL | TEST POINT | VALUE OF $y$ | SIGN OF $y$ |
|---|---|---|---|
| $(-\infty, -1)$ | $-2$ | $-\frac{3}{8}$ | $-$ |
| $(-1, 0)$ | $-\frac{1}{2}$ | $6$ | $+$ |
| $(0, 1)$ | $\frac{1}{2}$ | $-6$ | $-$ |
| $(1, +\infty)$ | $2$ | $\frac{3}{8}$ | $+$ |

- *Symmetries:* Replacing $x$ by $-x$ and $y$ by $-y$ yields an equation that simplifies to the original equation, so the graph is symmetric about the origin.
- *$x$- and $y$-intercepts:* Setting $y = 0$ yields the $x$-intercepts $x = -1$ and $x = 1$. Setting $x = 0$ leads to a division by zero, so there is no $y$-intercept.
- *Vertical asymptotes:* Setting $x^3 = 0$ yields the solution $x = 0$. This is not a root of $x^2 - 1$, so $x = 0$ is a vertical asymptote.
- *Sign of $y$:* The set of points where $x$-intercepts or vertical asymptotes occur is $\{-1, 0, 1\}$. These points divide the $x$-axis into the open intervals

$$(-\infty, -1), \quad (-1, 0), \quad (0, 1), \quad (1, +\infty)$$

Table 4.3.2 uses the method of test points to produce the sign of $y$ on each of these intervals.

- *End behavior:* The limits

$$\lim_{x\to+\infty} \frac{x^2-1}{x^3} = \lim_{x\to+\infty} \left(\frac{1}{x} - \frac{1}{x^3}\right) = 0$$
$$\lim_{x\to-\infty} \frac{x^2-1}{x^3} = \lim_{x\to-\infty} \left(\frac{1}{x} - \frac{1}{x^3}\right) = 0$$

yield the horizontal asymptote $y = 0$.

- *Derivatives:*

$$\frac{dy}{dx} = \frac{x^3(2x) - (x^2-1)(3x^2)}{(x^3)^2} = \frac{3-x^2}{x^4} = \frac{(\sqrt{3}+x)(\sqrt{3}-x)}{x^4}$$
$$\frac{d^2y}{dx^2} = \frac{x^4(-2x) - (3-x^2)(4x^3)}{(x^4)^2} = \frac{2(x^2-6)}{x^5} = \frac{2(x-\sqrt{6})(x+\sqrt{6})}{x^5}$$

*Conclusions and graph:*

- The sign analysis of $y$ in Figure 4.3.2*a* reveals the behavior of the graph in the vicinity of the vertical asymptote $x = 0$: The graph increases without bound as $x \to 0^-$ and decreases without bound as $x \to 0^+$ (Figure 4.3.2*b*).
- The sign analysis of $dy/dx$ in Figure 4.3.2*a* shows that there is a relative minimum at $x = -\sqrt{3}$ and a relative maximum at $x = \sqrt{3}$.
- The sign analysis of $d^2y/dx^2$ in Figure 4.3.2*a* shows that the graph changes concavity at the vertical asymptote $x = 0$ and that there are inflection points at $x = -\sqrt{6}$ and $x = \sqrt{6}$.

The graph is shown in Figure 4.3.2*c*. To produce a slightly more accurate sketch, we used a graphing utility to help plot the relative extrema and inflection points. You should confirm that the approximate coordinates of the inflection points are $(-2.45, -0.34)$ and $(2.45, 0.34)$ and that the approximate coordinates of the relative minimum and relative maximum are $(-1.73, -0.38)$ and $(1.73, 0.38)$, respectively. ◀

▲ **Figure 4.3.4**

## RATIONAL FUNCTIONS WITH OBLIQUE OR CURVILINEAR ASYMPTOTES

In the rational functions of Examples 1 and 2, the degree of the numerator did not exceed the degree of the denominator, and the asymptotes were either vertical or horizontal. If the numerator of a rational function has greater degree than the denominator, then other kinds of "asymptotes" are possible. For example, consider the rational functions

$$f(x) = \frac{x^2 + 1}{x} \quad \text{and} \quad g(x) = \frac{x^3 - x^2 - 8}{x - 1} \tag{1}$$

By division we can rewrite these as

$$f(x) = x + \frac{1}{x} \quad \text{and} \quad g(x) = x^2 - \frac{8}{x - 1}$$

Since the second terms both approach 0 as $x \to +\infty$ or as $x \to -\infty$, it follows that

$$(f(x) - x) \to 0 \quad \text{as } x \to +\infty \text{ or as } x \to -\infty$$
$$(g(x) - x^2) \to 0 \quad \text{as } x \to +\infty \text{ or as } x \to -\infty$$

Geometrically, this means that the graph of $y = f(x)$ eventually gets closer and closer to the line $y = x$ as $x \to +\infty$ or as $x \to -\infty$. The line $y = x$ is called an ***oblique*** or ***slant asymptote*** of $f$. Similarly, the graph of $y = g(x)$ eventually gets closer and closer to the parabola $y = x^2$ as $x \to +\infty$ or as $x \to -\infty$. The parabola is called a ***curvilinear asymptote*** of $g$. The graphs of the functions in (1) are shown in Figures 4.3.3 and 4.3.4.

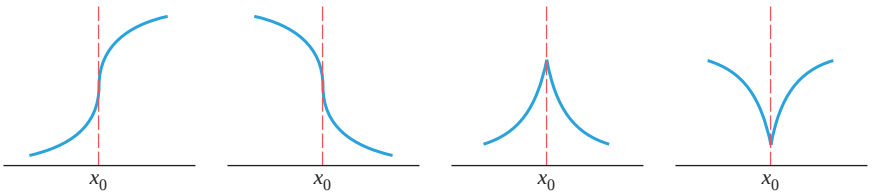
In general, if $f(x) = P(x)/Q(x)$ is a rational function, then we can find quotient and remainder polynomials $q(x)$ and $r(x)$ such that

$$f(x) = q(x) + \frac{r(x)}{Q(x)}$$

and the degree of $r(x)$ is less than the degree of $Q(x)$. Then $r(x)/Q(x) \to 0$ as $x \to +\infty$ and as $x \to -\infty$, so $y = q(x)$ is an asymptote of $f$. This asymptote will be an oblique line if the degree of $P(x)$ is one greater than the degree of $Q(x)$, and it will be curvilinear if the degree of $P(x)$ exceeds that of $Q(x)$ by two or more. Problems involving these kinds of asymptotes are given in the exercises (Exercises 17 and 18).

## GRAPHS WITH VERTICAL TANGENTS AND CUSPS

Figure 4.3.5 shows four curve elements that are commonly found in graphs of functions that involve radicals or fractional exponents. In all four cases, the function is not differentiable at $x_0$ because the secant line through $(x_0, f(x_0))$ and $(x, f(x))$ approaches a vertical position as $x$ approaches $x_0$ from either side. Thus, in each case, the curve has a vertical tangent line at $(x_0, f(x_0))$. In parts $(a)$ and $(b)$ of the figure, there is an inflection point at $x_0$ because there is a change in concavity at that point. In parts $(c)$ and $(d)$, where $f'(x)$ approaches $+\infty$ from one side of $x_0$ and $-\infty$ from the other side, we say that the graph has a ***cusp*** at $x_0$.



$(a)$ $(b)$ $(c)$ $(d)$

▶ **Figure 4.3.5**

The steps that are used to sketch the graph of a rational function can serve as guidelines for sketching graphs of other types of functions. This is illustrated in Examples 3, 4, and 5.

▶ **Example 3** Sketch the graph of $y = (x - 4)^{2/3}$.

- *Symmetries:* There are no symmetries about the coordinate axes or the origin (verify). However, the graph of $y = (x - 4)^{2/3}$ is symmetric about the line $x = 4$ since it is a translation (4 units to the right) of the graph of $y = x^{2/3}$, which is symmetric about the $y$-axis.
- *$x$- and $y$-intercepts:* Setting $y = 0$ yields the $x$-intercept $x = 4$. Setting $x = 0$ yields the $y$-intercept $y = \sqrt[3]{16} \approx 2.5$.
- *Vertical asymptotes:* None, since $f(x) = (x - 4)^{2/3}$ is continuous everywhere.
- *End behavior:* The graph has no horizontal asymptotes since

$$\lim_{x \to +\infty} (x - 4)^{2/3} = +\infty \quad \text{and} \quad \lim_{x \to -\infty} (x - 4)^{2/3} = +\infty$$

- *Derivatives:*

$$\frac{dy}{dx} = f'(x) = \frac{2}{3}(x - 4)^{-1/3} = \frac{2}{3(x - 4)^{1/3}}$$

$$\frac{d^2y}{dx^2} = f''(x) = -\frac{2}{9}(x - 4)^{-4/3} = -\frac{2}{9(x - 4)^{4/3}}$$

- *Vertical tangent lines:* There is a vertical tangent line and cusp at $x = 4$ of the type in Figure 4.3.5*d* since $f(x) = (x - 4)^{2/3}$ is continuous at $x = 4$ and

$$\lim_{x \to 4^+} f'(x) = \lim_{x \to 4^+} \frac{2}{3(x - 4)^{1/3}} = +\infty$$

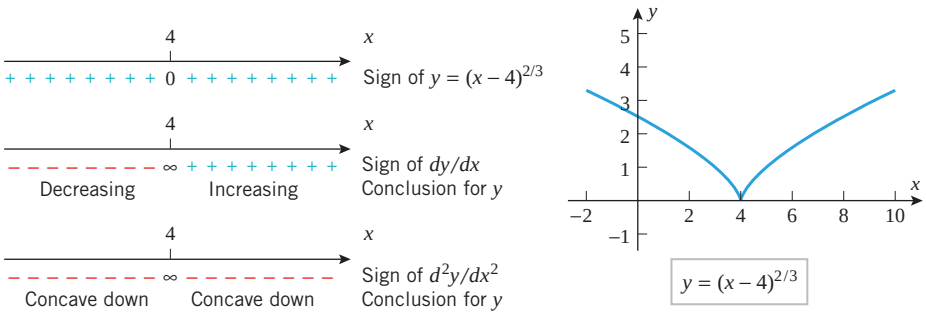
$$\lim_{x \to 4^-} f'(x) = \lim_{x \to 4^-} \frac{2}{3(x - 4)^{1/3}} = -\infty$$

*Conclusions and graph:*

- The function $f(x) = (x - 4)^{2/3} = ((x - 4)^{1/3})^2$ is nonnegative for all $x$. There is a zero for $f$ at $x = 4$.

- There is a critical point at $x = 4$ since $f$ is not differentiable there. We saw above that a cusp occurs at this point. The sign analysis of $dy/dx$ in Figure 4.3.6*a* and the first derivative test show that there is a relative minimum at this cusp since $f'(x) < 0$ if $x < 4$ and $f'(x) > 0$ if $x > 4$.
- The sign analysis of $d^2y/dx^2$ in Figure 4.3.6*a* shows that the graph is concave down on both sides of the cusp.

The graph is shown in Figure 4.3.6*b*. ◀



▶ **Figure 4.3.6**

▶ **Example 4** Sketch the graph of $y = 6x^{1/3} + 3x^{4/3}$.

***Solution.*** It will help in our analysis to write

$$f(x) = 6x^{1/3} + 3x^{4/3} = 3x^{1/3}(2 + x)$$

- *Symmetries:* There are no symmetries about the coordinate axes or the origin (verify).
- $x$- and $y$-*intercepts:* Setting $y = 3x^{1/3}(2 + x) = 0$ yields the $x$-intercepts $x = 0$ and $x = -2$. Setting $x = 0$ yields the $y$-intercept $y = 0$.
- *Vertical asymptotes:* None, since $f(x) = 6x^{1/3} + 3x^{4/3}$ is continuous everywhere.
- *End behavior:* The graph has no horizontal asymptotes since

$$\lim_{x \to +\infty} (6x^{1/3} + 3x^{4/3}) = \lim_{x \to +\infty} 3x^{1/3}(2 + x) = +\infty$$

$$\lim_{x \to -\infty} (6x^{1/3} + 3x^{4/3}) = \lim_{x \to -\infty} 3x^{1/3}(2 + x) = +\infty$$

- *Derivatives:*

$$\frac{dy}{dx} = f'(x) = 2x^{-2/3} + 4x^{1/3} = 2x^{-2/3}(1 + 2x) = \frac{2(2x + 1)}{x^{2/3}}$$

$$\frac{d^2y}{dx^2} = f''(x) = -\frac{4}{3}x^{-5/3} + \frac{4}{3}x^{-2/3} = \frac{4}{3}x^{-5/3}(-1 + x) = \frac{4(x - 1)}{3x^{5/3}}$$

- *Vertical tangent lines:* There is a vertical tangent line at $x = 0$ since $f$ is continuous there and

$$\lim_{x \to 0^+} f'(x) = \lim_{x \to 0^+} \frac{2(2x + 1)}{x^{2/3}} = +\infty$$

$$\lim_{x \to 0^-} f'(x) = \lim_{x \to 0^-} \frac{2(2x + 1)}{x^{2/3}} = +\infty$$

This and the change in concavity at $x = 0$ mean that $(0, 0)$ is an inflection point of the type in Figure 4.3.5*a*.

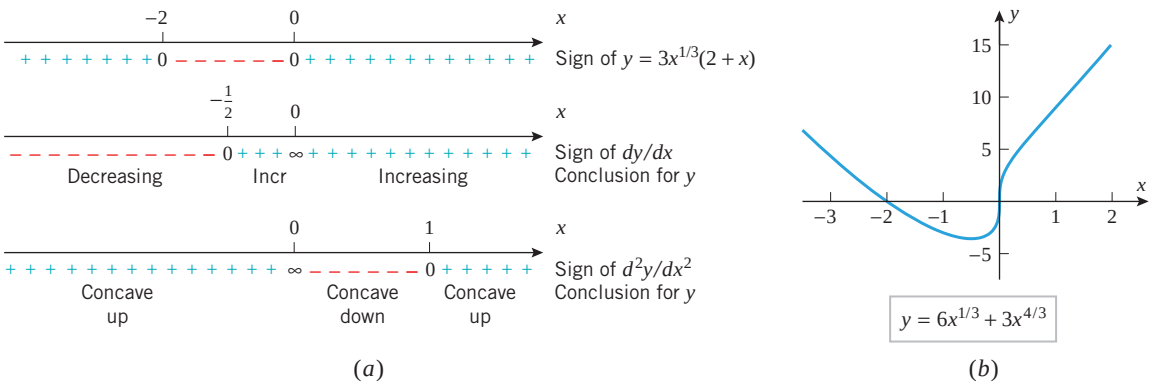
*Conclusions and graph:*

- From the sign analysis of $y$ in Figure 4.3.7*a*, the graph is below the $x$-axis between the $x$-intercepts $x = -2$ and $x = 0$ and is above the $x$-axis if $x < -2$ or $x > 0$.
- From the formula for $dy/dx$ we see that there is a stationary point at $x = -\frac{1}{2}$ and a critical point at $x = 0$ at which $f$ is not differentiable. We saw above that a vertical tangent line and inflection point are at that critical point.
- The sign analysis of $dy/dx$ in Figure 4.3.7*a* and the first derivative test show that there is a relative minimum at the stationary point at $x = -\frac{1}{2}$ (verify).
- The sign analysis of $d^2y/dx^2$ in Figure 4.3.7*a* shows that in addition to the inflection point at the vertical tangent there is an inflection point at $x = 1$ at which the graph changes from concave down to concave up.

**TECHNOLOGY MASTERY**

The graph in Figure 4.3.7*b* was generated with a graphing utility. However, the inflection point at $x = 1$ is so subtle that it is not evident from this graph. See if you can produce a version of this graph with your graphing utility that makes the inflection point evident.

The graph is shown in Figure 4.3.7*b*. ◀



▲ **Figure 4.3.7**

## GRAPHING OTHER KINDS OF FUNCTIONS

We have discussed methods for graphing polynomials, rational functions, and functions with cusps and vertical tangent lines. The same calculus tools that we used to analyze these functions can also be used to analyze and graph trigonometric functions, logarithmic and exponential functions, and an endless variety of other kinds of functions.

▶ **Example 5** Sketch the graph of $y = e^{-x^2/2}$ and identify the locations of all relative extrema and inflection points.

***Solution.***

- *Symmetries:* Replacing $x$ by $-x$ does not change the equation, so the graph is symmetric about the $y$-axis.
- *$x$- and $y$-intercepts:* Setting $y = 0$ leads to the equation $e^{-x^2/2} = 0$, which has no solutions since all powers of $e$ have positive values. Thus, there are no $x$-intercepts. Setting $x = 0$ yields the $y$-intercept $y = 1$.
- *Vertical asymptotes:* There are no vertical asymptotes since $e^{-x^2/2}$ is continuous on $(-\infty, +\infty)$.
- *End behavior:* The $x$-axis ($y = 0$) is a horizontal asymptote since

$$\lim_{x \to -\infty} e^{-x^2/2} = \lim_{x \to +\infty} e^{-x^2/2} = 0$$

- *Derivatives:*

$$\frac{dy}{dx} = e^{-x^2/2}\frac{d}{dx}\left[-\frac{x^2}{2}\right] = -xe^{-x^2/2}$$

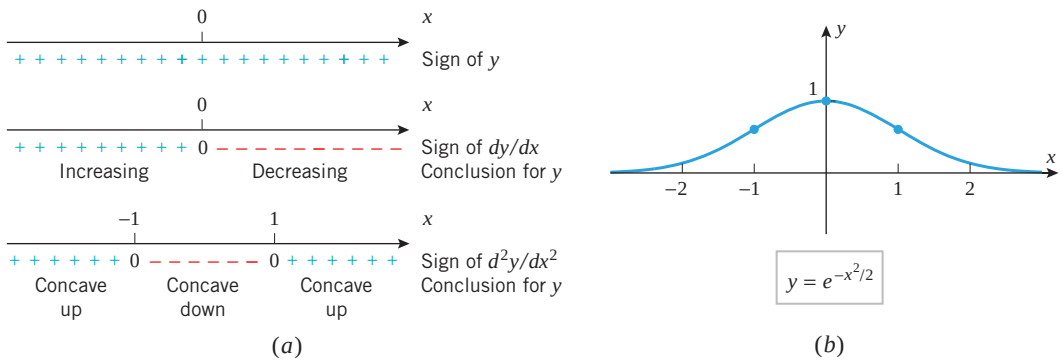
$$\frac{d^2y}{dx^2} = -x\frac{d}{dx}[e^{-x^2/2}] + e^{-x^2/2}\frac{d}{dx}[-x]$$

$$= x^2e^{-x^2/2} - e^{-x^2/2} = (x^2 - 1)e^{-x^2/2}$$

*Conclusions and graph:*

- The sign analysis of $y$ in Figure 4.3.8*a* is based on the fact that $e^{-x^2/2} > 0$ for all $x$. This shows that the graph is always above the $x$-axis.
- The sign analysis of $dy/dx$ in Figure 4.3.8*a* is based on the fact that $dy/dx = -xe^{-x^2/2}$ has the same sign as $-x$. This analysis and the first derivative test show that there is a stationary point at $x = 0$ at which there is a relative maximum. The value of $y$ at the relative maximum is $y = e^0 = 1$.
- The sign analysis of $d^2y/dx^2$ in Figure 4.3.8*a* is based on the fact that $d^2y/dx^2 = (x^2 - 1)e^{-x^2/2}$ has the same sign as $x^2 - 1$. This analysis shows that there are inflection points at $x = -1$ and $x = 1$. The graph changes from concave up to concave down at $x = -1$ and from concave down to concave up at $x = 1$. The coordinates of the inflection points are $(-1, e^{-1/2}) \approx (-1, 0.61)$ and $(1, e^{-1/2}) \approx (1, 0.61)$.

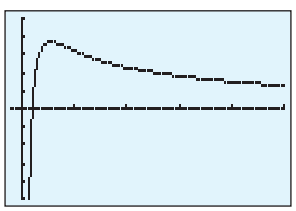
The graph is shown in Figure 4.3.8*b*. ◄



▲ **Figure 4.3.8**

## GRAPHING USING CALCULUS AND TECHNOLOGY TOGETHER

Thus far in this chapter we have used calculus to produce graphs of functions; the graph was the end result. Now we will work in the reverse direction by *starting* with a graph produced by a graphing utility. Our goal will be to use the tools of calculus to determine the exact locations of relative extrema, inflection points, and other features suggested by that graph and to determine whether the graph may be missing some important features that we would like to see.



[−1, 25] × [−0.5, 0.5]
xScl = 5, yScl = 0.2

$y = \dfrac{\ln x}{x}$

▲ **Figure 4.3.9**

► **Example 6** Use a graphing utility to generate the graph of $f(x) = (\ln x)/x$, and discuss what it tells you about relative extrema, inflection points, asymptotes, and end behavior. Use calculus to find the locations of all key features of the graph.

***Solution.*** Figure 4.3.9 shows a graph of $f$ produced by a graphing utility. The graph suggests that there is an $x$-intercept near $x = 1$, a relative maximum somewhere between

$x = 0$ and $x = 5$, an inflection point near $x = 5$, a vertical asymptote at $x = 0$, and possibly a horizontal asymptote $y = 0$. For a more precise analysis of this information we need to consider the derivatives

$$f'(x) = \frac{x\left(\frac{1}{x}\right) - (\ln x)(1)}{x^2} = \frac{1 - \ln x}{x^2}$$

$$f''(x) = \frac{x^2\left(-\frac{1}{x}\right) - (1 - \ln x)(2x)}{x^4} = \frac{2x \ln x - 3x}{x^4} = \frac{2 \ln x - 3}{x^3}$$

- *Relative extrema:* Solving $f'(x) = 0$ yields the stationary point $x = e$ (verify). Since
$$f''(e) = \frac{2 - 3}{e^3} = -\frac{1}{e^3} < 0$$
there is a relative maximum at $x = e \approx 2.7$ by the second derivative test.
- *Inflection points:* Since $f(x) = (\ln x)/x$ is only defined for positive values of $x$, the second derivative $f''(x)$ has the same sign as $2 \ln x - 3$. We leave it for you to use the inequalities $(2 \ln x - 3) < 0$ and $(2 \ln x - 3) > 0$ to show that $f''(x) < 0$ if $x < e^{3/2}$ and $f''(x) > 0$ if $x > e^{3/2}$. Thus, there is an inflection point at $x = e^{3/2} \approx 4.5$.
- *Asymptotes:* Applying L'Hôpital's rule we have
$$\lim_{x \to +\infty} \frac{\ln x}{x} = \lim_{x \to +\infty} \frac{(1/x)}{1} = \lim_{x \to +\infty} \frac{1}{x} = 0$$
so that $y = 0$ is a horizontal asymptote. Also, there is a vertical asymptote at $x = 0$ since
$$\lim_{x \to 0^+} \frac{\ln x}{x} = -\infty$$
(why?).
- *Intercepts:* Setting $f(x) = 0$ yields $(\ln x)/x = 0$. The only real solution of this equation is $x = 1$, so there is an $x$-intercept at this point. ◀

## ✔ QUICK CHECK EXERCISES 4.3 (See page 266 for answers.)

**1.** Let $f(x) = \dfrac{3(x + 1)(x - 3)}{(x + 2)(x - 4)}$. Given that

$$f'(x) = \frac{-30(x - 1)}{(x + 2)^2(x - 4)^2}, \qquad f''(x) = \frac{90(x^2 - 2x + 4)}{(x + 2)^3(x - 4)^3}$$

determine the following properties of the graph of $f$.

(a) The $x$- and $y$-intercepts are _____.
(b) The vertical asymptotes are _____.
(c) The horizontal asymptote is _____.
(d) The graph is above the $x$-axis on the intervals _____.
(e) The graph is increasing on the intervals _____.
(f) The graph is concave up on the intervals _____.
(g) The relative maximum point on the graph is _____.

**2.** Let $f(x) = \dfrac{x^2 - 4}{x^{8/3}}$. Given that

$$f'(x) = \frac{-2(x^2 - 16)}{3x^{11/3}}, \qquad f''(x) = \frac{2(5x^2 - 176)}{9x^{14/3}}$$

determine the following properties of the graph of $f$.

(a) The $x$-intercepts are _____.
(b) The vertical asymptote is _____.
(c) The horizontal asymptote is _____.
(d) The graph is above the $x$-axis on the intervals _____.
(e) The graph is increasing on the intervals _____.
(f) The graph is concave up on the intervals _____.
(g) Inflection points occur at $x =$ _____.

**3.** Let $f(x) = (x - 2)^2 e^{x/2}$. Given that

$$f'(x) = \tfrac{1}{2}(x^2 - 4)e^{x/2}, \qquad f''(x) = \tfrac{1}{4}(x^2 + 4x - 4)e^{x/2}$$

determine the following properties of the graph of $f$.

(a) The horizontal asymptote is _____.
(b) The graph is above the $x$-axis on the intervals _____.
(c) The graph is increasing on the intervals _____.
(d) The graph is concave up on the intervals _____.
(e) The relative minimum point on the graph is _____.
(f) The relative maximum point on the graph is _____.
(g) Inflection points occur at $x =$ _____.

## EXERCISE SET 4.3 Graphing Utility

**1–14** Give a graph of the rational function and label the coordinates of the stationary points and inflection points. Show the horizontal and vertical asymptotes and label them with their equations. Label point(s), if any, where the graph crosses a horizontal asymptote. Check your work with a graphing utility. ■

**1.** $\dfrac{2x-6}{4-x}$ **2.** $\dfrac{8}{x^2-4}$ **3.** $\dfrac{x}{x^2-4}$

**4.** $\dfrac{x^2}{x^2-4}$ **5.** $\dfrac{x^2}{x^2+4}$ **6.** $\dfrac{(x^2-1)^2}{x^4+1}$

**7.** $\dfrac{x^3+1}{x^3-1}$ **8.** $2-\dfrac{1}{3x^2+x^3}$

**9.** $\dfrac{4}{x^2}-\dfrac{2}{x}+3$ **10.** $\dfrac{3(x+1)^2}{(x-1)^2}$

**11.** $\dfrac{(3x+1)^2}{(x-1)^2}$ **12.** $3+\dfrac{x+1}{(x-1)^4}$

**13.** $\dfrac{x^2+x}{1-x^2}$ **14.** $\dfrac{x^2}{1-x^3}$

**15–16** In each part, make a rough sketch of the graph using asymptotes and appropriate limits but no derivatives. Compare your graph to that generated with a graphing utility. ■

**15.** (a) $y=\dfrac{3x^2-8}{x^2-4}$ (b) $y=\dfrac{x^2+2x}{x^2-1}$

**16.** (a) $y=\dfrac{2x-x^2}{x^2+x-2}$ (b) $y=\dfrac{x^2}{x^2-x-2}$

**17.** Show that $y=x+3$ is an oblique asymptote of the graph of $f(x)=x^2/(x-3)$. Sketch the graph of $y=f(x)$ showing this asymptotic behavior.

**18.** Show that $y=3-x^2$ is a curvilinear asymptote of the graph of $f(x)=(2+3x-x^3)/x$. Sketch the graph of $y=f(x)$ showing this asymptotic behavior.

**19–24** Sketch a graph of the rational function and label the coordinates of the stationary points and inflection points. Show the horizontal, vertical, oblique, and curvilinear asymptotes and label them with their equations. Label point(s), if any, where the graph crosses an asymptote. Check your work with a graphing utility. ■

**19.** $x^2-\dfrac{1}{x}$ **20.** $\dfrac{x^2-2}{x}$

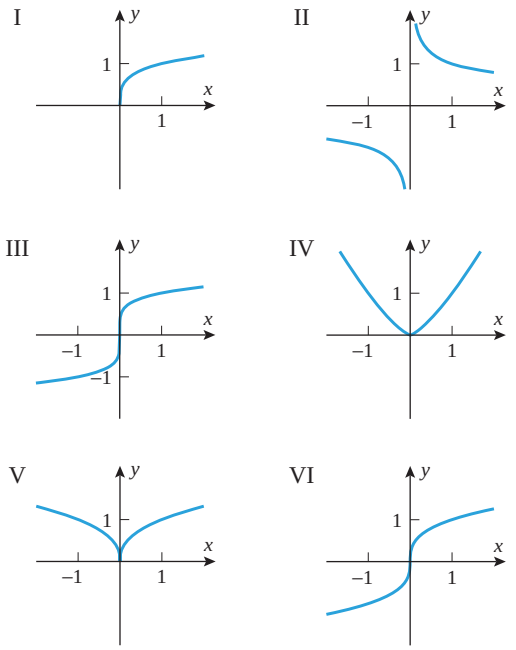
**21.** $\dfrac{(x-2)^3}{x^2}$ **22.** $x-\dfrac{1}{x}-\dfrac{1}{x^2}$

**23.** $\dfrac{x^3-4x-8}{x+2}$ **24.** $\dfrac{x^5}{x^2+1}$

### FOCUS ON CONCEPTS

**25.** In each part, match the function with graphs I–VI.

(a) $x^{1/3}$ (b) $x^{1/4}$ (c) $x^{1/5}$
(d) $x^{2/5}$ (e) $x^{4/3}$ (f) $x^{-1/3}$



▲ **Figure Ex-25**

**26.** Sketch the general shape of the graph of $y=x^{1/n}$, and then explain in words what happens to the shape of the graph as $n$ increases if

(a) $n$ is a positive even integer
(b) $n$ is a positive odd integer.

**27–30 True–False** Determine whether the statement is true or false. Explain your answer. ■

**27.** Suppose that $f(x)=P(x)/Q(x)$, where $P$ and $Q$ are polynomials with no common factors. If $y=5$ is a horizontal asymptote for the graph of $f$, then $P$ and $Q$ have the same degree.

**28.** If the graph of $f$ has a vertical asymptote at $x=1$, then $f$ cannot be continuous at $x=1$.

**29.** If the graph of $f'$ has a vertical asymptote at $x=1$, then $f$ cannot be continuous at $x=1$.

**30.** If the graph of $f$ has a cusp at $x=1$, then $f$ cannot have an inflection point at $x=1$.

**31–38** Give a graph of the function and identify the locations of all critical points and inflection points. Check your work with a graphing utility. ■

**31.** $\sqrt{4x^2-1}$ **32.** $\sqrt[3]{x^2-4}$

**33.** $2x+3x^{2/3}$ **34.** $2x^2-3x^{4/3}$

**35.** $4x^{1/3}-x^{4/3}$ **36.** $5x^{2/3}+x^{5/3}$

**37.** $\dfrac{8+x}{2+\sqrt[3]{x}}$ **38.** $\dfrac{8(\sqrt{x}-1)}{x}$

**39–44** Give a graph of the function and identify the locations of all relative extrema and inflection points. Check your work with a graphing utility. ■

**39.** $x + \sin x$

**40.** $x - \tan x$

**41.** $\sqrt{3}\cos x + \sin x$

**42.** $\sin x + \cos x$

**43.** $\sin^2 x - \cos x, \quad -\pi \le x \le 3\pi$

**44.** $\sqrt{\tan x}, \quad 0 \le x < \pi/2$

**45–54** Using L'Hôpital's rule (Section 3.6) one can verify that

$$\lim_{x\to+\infty} \frac{e^x}{x} = +\infty, \quad \lim_{x\to+\infty} \frac{x}{e^x} = 0, \quad \lim_{x\to-\infty} xe^x = 0$$

In these exercises: (a) Use these results, as necessary, to find the limits of $f(x)$ as $x \to +\infty$ and as $x \to -\infty$. (b) Sketch a graph of $f(x)$ and identify all relative extrema, inflection points, and asymptotes (as appropriate). Check your work with a graphing utility. ■

**45.** $f(x) = xe^x$

**46.** $f(x) = xe^{-x}$

**47.** $f(x) = x^2e^{-2x}$

**48.** $f(x) = x^2e^{2x}$

**49.** $f(x) = x^2e^{-x^2}$

**50.** $f(x) = e^{-1/x^2}$

**51.** $f(x) = \dfrac{e^x}{1-x}$

**52.** $f(x) = x^{2/3}e^x$

**53.** $f(x) = x^2e^{1-x}$

**54.** $f(x) = x^3e^{x-1}$

**55–60** Using L'Hôpital's rule (Section 3.6) one can verify that

$$\lim_{x\to+\infty} \frac{\ln x}{x^r} = 0, \quad \lim_{x\to+\infty} \frac{x^r}{\ln x} = +\infty, \quad \lim_{x\to0^+} x^r \ln x = 0$$

for any positive real number $r$. In these exercises: (a) Use these results, as necessary, to find the limits of $f(x)$ as $x \to +\infty$ and as $x \to 0^+$. (b) Sketch a graph of $f(x)$ and identify all relative extrema, inflection points, and asymptotes (as appropriate). Check your work with a graphing utility. ■

**55.** $f(x) = x \ln x$

**56.** $f(x) = x^2 \ln x$

**57.** $f(x) = x^2 \ln(2x)$

**58.** $f(x) = \ln(x^2 + 1)$

**59.** $f(x) = x^{2/3} \ln x$

**60.** $f(x) = x^{-1/3} \ln x$

## FOCUS ON CONCEPTS

**61.** Consider the family of curves $y = xe^{-bx}$ $(b > 0)$.
(a) Use a graphing utility to generate some members of this family.
(b) Discuss the effect of varying $b$ on the shape of the graph, and discuss the locations of the relative extrema and inflection points.

**62.** Consider the family of curves $y = e^{-bx^2}$ $(b > 0)$.
(a) Use a graphing utility to generate some members of this family.
(b) Discuss the effect of varying $b$ on the shape of the graph, and discuss the locations of the relative extrema and inflection points.

**63.** (a) Determine whether the following limits exist, and if so, find them:

$$\lim_{x\to+\infty} e^x \cos x, \quad \lim_{x\to-\infty} e^x \cos x$$

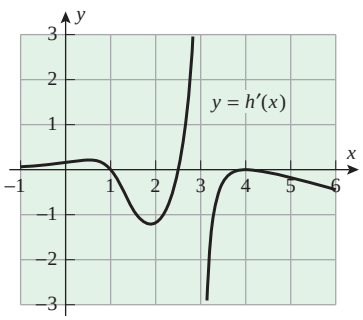
(b) Sketch the graphs of the equations $y = e^x$, $y = -e^x$, and $y = e^x \cos x$ in the same coordinate system, and label any points of intersection.
(c) Use a graphing utility to generate some members of the family $y = e^{ax}\cos bx$ $(a > 0$ and $b > 0)$, and discuss the effect of varying $a$ and $b$ on the shape of the curve.

**64.** Consider the family of curves $y = x^n e^{-x^2/n}$, where $n$ is a positive integer.
(a) Use a graphing utility to generate some members of this family.
(b) Discuss the effect of varying $n$ on the shape of the graph, and discuss the locations of the relative extrema and inflection points.

**65.** The accompanying figure shows the graph of the *derivative* of a function $h$ that is defined and continuous on the interval $(-\infty, +\infty)$. Assume that the graph of $h'$ has a vertical asymptote at $x = 3$ and that

$$h'(x) \to 0^+ \text{ as } x \to -\infty$$
$$h'(x) \to -\infty \text{ as } x \to +\infty$$

(a) What are the critical points for $h(x)$?
(b) Identify the intervals on which $h(x)$ is increasing.
(c) Identify the $x$-coordinates of relative extrema for $h(x)$ and classify each as a relative maximum or relative minimum.
(d) Estimate the $x$-coordinates of inflection points for $h(x)$.



◀ **Figure Ex-65**

**66.** Let $f(x) = (1 - 2x)h(x)$, where $h(x)$ is as given in Exercise 65. Suppose that $x = 5$ is a critical point for $f(x)$.
(a) Estimate $h(5)$.
(b) Use the second derivative test to determine whether $f(x)$ has a relative maximum or a relative minimum at $x = 5$.

# 4.4 ABSOLUTE MAXIMA AND MINIMA

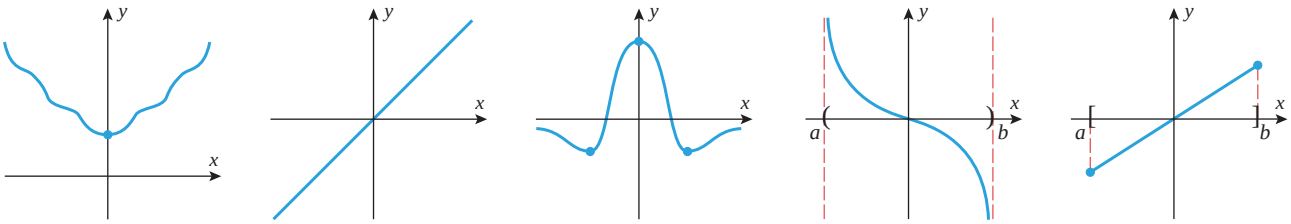
*At the beginning of Section 4.2 we observed that if the graph of a function $f$ is viewed as a two-dimensional mountain range (Figure 4.2.1), then the relative maxima and minima correspond to the tops of the hills and the bottoms of the valleys; that is, they are the high and low points in their immediate vicinity. In this section we will be concerned with the more encompassing problem of finding the highest and lowest points over the entire mountain range, that is, we will be looking for the top of the highest hill and the bottom of the deepest valley. In mathematical terms, we will be looking for the largest and smallest values of a function over an interval.*

## ABSOLUTE EXTREMA

We will begin with some terminology for describing the largest and smallest values of a function on an interval.

**4.4.1 DEFINITION** Consider an interval in the domain of a function $f$ and a point $x_0$ in that interval. We say that $f$ has an ***absolute maximum*** at $x_0$ if $f(x) \le f(x_0)$ for all $x$ in the interval, and we say that $f$ has an ***absolute minimum*** at $x_0$ if $f(x_0) \le f(x)$ for all $x$ in the interval. We say that $f$ has an ***absolute extremum*** at $x_0$ if it has either an absolute maximum or an absolute minimum at that point.

If $f$ has an absolute maximum at the point $x_0$ on an interval, then $f(x_0)$ is the largest value of $f$ on the interval, and if $f$ has an absolute minimum at $x_0$, then $f(x_0)$ is the smallest value of $f$ on the interval. In general, there is no guarantee that a function will actually have an absolute maximum or minimum on a given interval (Figure 4.4.1).



$f$ has an absolute minimum but no absolute maximum on $(-\infty, +\infty)$. (a)

$f$ has no absolute extrema on $(-\infty, +\infty)$. (b)

$f$ has an absolute maximum and minimum on $(-\infty, +\infty)$. (c)

$f$ has no absolute extrema on $(a, b)$. (d)

$f$ has an absolute maximum and minimum on $[a, b]$. (e)

▲ **Figure 4.4.1**

## THE EXTREME VALUE THEOREM

Parts $(a)$–$(d)$ of Figure 4.4.1 show that a continuous function may or may not have absolute maxima or minima on an infinite interval or on a finite open interval. However, the following theorem shows that a continuous function must have both an absolute maximum and an absolute minimum on every *finite closed* interval [see part $(e)$ of Figure 4.4.1].

The hypotheses in the Extreme-Value Theorem are essential. That is, if either the interval is not closed or $f$ is not continuous on the interval, then $f$ need not have absolute extrema on the interval (Exercises 4–6).

**4.4.2 THEOREM** (***Extreme-Value Theorem***) *If a function $f$ is continuous on a finite closed interval $[a, b]$, then $f$ has both an absolute maximum and an absolute minimum on $[a, b]$.*

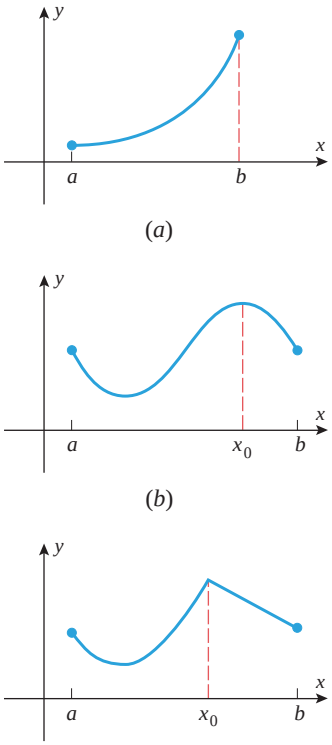
**REMARK** Although the proof of this theorem is too difficult to include here, you should be able to convince yourself of its validity with a little experimentation—try graphing various continuous functions over the interval $[0, 1]$, and convince yourself that there is no way to avoid having a highest and lowest point on a graph. As a physical analogy, if you imagine the graph to be a roller-coaster track starting at $x = 0$ and ending at $x = 1$, the roller coaster will have to pass through a highest point and a lowest point during the trip.

The Extreme-Value Theorem is an example of what mathematicians call an ***existence theorem***. Such theorems state conditions under which certain objects exist, in this case absolute extrema. However, knowing that an object exists and finding it are two separate things. We will now address methods for determining the locations of absolute extrema under the conditions of the Extreme-Value Theorem.

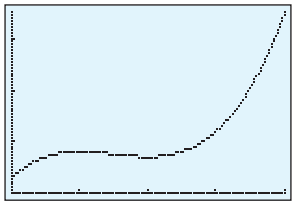
If $f$ is continuous on the finite closed interval $[a, b]$, then the absolute extrema of $f$ occur either at the endpoints of the interval or inside on the open interval $(a, b)$. If the absolute extrema happen to fall inside, then the following theorem tells us that they must occur at critical points of $f$.

Theorem 4.4.3 is also valid on infinite open intervals, that is, intervals of the form $(-\infty, +\infty)$, $(a, +\infty)$, and $(-\infty, b)$.

**4.4.3 THEOREM** *If $f$ has an absolute extremum on an open interval $(a, b)$, then it must occur at a critical point of $f$.*



▲ **Figure 4.4.2** In part (*a*) the absolute maximum occurs at an endpoint of $[a, b]$, in part (*b*) it occurs at a stationary point in $(a, b)$, and in part (*c*) it occurs at a critical point in $(a, b)$ where $f$ is not differentiable.



▲ **Figure 4.4.3**

**Table 4.4.1**

| $x$ | $-1$ | $0$ | $\frac{1}{8}$ | $1$ |
|---|---|---|---|---|
| $f(x)$ | $9$ | $0$ | $-\frac{9}{8}$ | $3$ |

**PROOF** If $f$ has an absolute maximum on $(a, b)$ at $x_0$, then $f(x_0)$ is also a relative maximum for $f$; for if $f(x_0)$ is the largest value of $f$ on all $(a, b)$, then $f(x_0)$ is certainly the largest value for $f$ in the immediate vicinity of $x_0$. Thus, $x_0$ is a critical point of $f$ by Theorem 4.2.2. The proof for absolute minima is similar. ■

It follows from this theorem that if $f$ is continuous on the finite closed interval $[a, b]$, then the absolute extrema occur either at the endpoints of the interval or at critical points inside the interval (Figure 4.4.2). Thus, we can use the following procedure to find the absolute extrema of a continuous function on a finite closed interval $[a, b]$.

***A Procedure for Finding the Absolute Extrema of a Continuous Function f on a Finite Closed Interval [a, b]***

**Step 1.** Find the critical points of $f$ in $(a, b)$.

**Step 2.** Evaluate $f$ at all the critical points and at the endpoints $a$ and $b$.

**Step 3.** The largest of the values in Step 2 is the absolute maximum value of $f$ on $[a, b]$ and the smallest value is the absolute minimum.

▶ **Example 1** Find the absolute maximum and minimum values of the function $f(x) = 2x^3 - 15x^2 + 36x$ on the interval $[1, 5]$, and determine where these values occur.

***Solution.*** Since $f$ is continuous and differentiable everywhere, the absolute extrema must occur either at endpoints of the interval or at solutions to the equation $f'(x) = 0$ in the open interval $(1, 5)$. The equation $f'(x) = 0$ can be written as

$$6x^2 - 30x + 36 = 6(x^2 - 5x + 6) = 6(x - 2)(x - 3) = 0$$

Thus, there are stationary points at $x = 2$ and at $x = 3$. Evaluating $f$ at the endpoints, at $x = 2$, and at $x = 3$ yields

$$f(1) = 2(1)^3 - 15(1)^2 + 36(1) = 23$$
$$f(2) = 2(2)^3 - 15(2)^2 + 36(2) = 28$$
$$f(3) = 2(3)^3 - 15(3)^2 + 36(3) = 27$$
$$f(5) = 2(5)^3 - 15(5)^2 + 36(5) = 55$$

from which we conclude that the absolute minimum of $f$ on $[1, 5]$ is 23, occurring at $x = 1$, and the absolute maximum of $f$ on $[1, 5]$ is 55, occurring at $x = 5$. This is consistent with the graph of $f$ in Figure 4.4.3. ◀

▶ **Example 2** Find the absolute extrema of $f(x) = 6x^{4/3} - 3x^{1/3}$ on the interval $[-1, 1]$, and determine where these values occur.

***Solution.*** Note that $f$ is continuous everywhere and therefore the Extreme-Value Theorem guarantees that $f$ has a maximum and a minimum value in the interval $[-1, 1]$. Differentiating, we obtain

$$f'(x) = 8x^{1/3} - x^{-2/3} = x^{-2/3}(8x - 1) = \frac{8x - 1}{x^{2/3}}$$

Thus, $f'(x) = 0$ at $x = \frac{1}{8}$, and $f'(x)$ is undefined at $x = 0$. Evaluating $f$ at these critical points and endpoints yields Table 4.4.1, from which we conclude that an absolute minimum value of $-\frac{9}{8}$ occurs at $x = \frac{1}{8}$, and an absolute maximum value of 9 occurs at $x = -1$. ◀

## ABSOLUTE EXTREMA ON INFINITE INTERVALS

We observed earlier that a continuous function may or may not have absolute extrema on an infinite interval (see Figure 4.4.1). However, certain conclusions about the existence of absolute extrema of a continuous function $f$ on $(-\infty, +\infty)$ can be drawn from the behavior of $f(x)$ as $x \to -\infty$ and as $x \to +\infty$ (Table 4.4.2).

**Table 4.4.2**

ABSOLUTE EXTREMA ON INFINITE INTERVALS

| | | | | |
|---|---|---|---|---|
| **LIMITS** | $\lim_{x\to-\infty} f(x) = +\infty$<br>$\lim_{x\to+\infty} f(x) = +\infty$ | $\lim_{x\to-\infty} f(x) = -\infty$<br>$\lim_{x\to+\infty} f(x) = -\infty$ | $\lim_{x\to-\infty} f(x) = -\infty$<br>$\lim_{x\to+\infty} f(x) = +\infty$ | $\lim_{x\to-\infty} f(x) = +\infty$<br>$\lim_{x\to+\infty} f(x) = -\infty$ |
| **CONCLUSION IF $f$ IS CONTINUOUS EVERYWHERE** | $f$ has an absolute minimum but no absolute maximum on $(-\infty, +\infty)$. | $f$ has an absolute maximum but no absolute minimum on $(-\infty, +\infty)$. | $f$ has neither an absolute maximum nor an absolute minimum on $(-\infty, +\infty)$. | $f$ has neither an absolute maximum nor an absolute minimum on $(-\infty, +\infty)$. |
| **GRAPH** |  |  |  |  |

**▶ Example 3** What can you say about the existence of absolute extrema on $(-\infty, +\infty)$ for polynomials?

***Solution.*** If $p(x)$ is a polynomial of odd degree, then

$$\lim_{x\to+\infty} p(x) \quad \text{and} \quad \lim_{x\to-\infty} p(x) \tag{1}$$

have opposite signs (one is $+\infty$ and the other is $-\infty$), so there are no absolute extrema. On the other hand, if $p(x)$ has even degree, then the limits in (1) have the same sign (both $+\infty$ or both $-\infty$). If the leading coefficient is positive, then both limits are $+\infty$, and there is an absolute minimum but no absolute maximum; if the leading coefficient is negative, then both limits are $-\infty$, and there is an absolute maximum but no absolute minimum. ◀

**▶ Example 4** Determine by inspection whether $p(x) = 3x^4 + 4x^3$ has any absolute extrema. If so, find them and state where they occur.

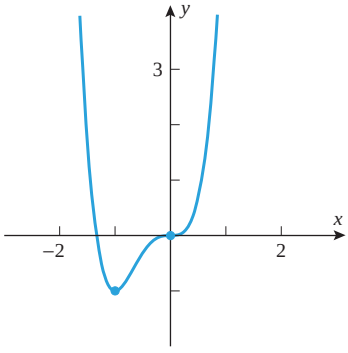
***Solution.*** Since $p(x)$ has even degree and the leading coefficient is positive, $p(x) \to +\infty$ as $x \to \pm\infty$. Thus, there is an absolute minimum but no absolute maximum. From Theorem 4.4.3 [applied to the interval $(-\infty, +\infty)$], the absolute minimum must occur at a critical point of $p$. Since $p$ is differentiable everywhere, we can find all critical points by solving the equation $p'(x) = 0$. This equation is

$$12x^3 + 12x^2 = 12x^2(x + 1) = 0$$

from which we conclude that the critical points are $x = 0$ and $x = -1$. Evaluating $p$ at these critical points yields

$$p(0) = 0 \quad \text{and} \quad p(-1) = -1$$

Therefore, $p$ has an absolute minimum of $-1$ at $x = -1$ (Figure 4.4.4). ◀



▲ **Figure 4.4.4**

## ABSOLUTE EXTREMA ON OPEN INTERVALS

We know that a continuous function may or may not have absolute extrema on an open interval. However, certain conclusions about the existence of absolute extrema of a continuous function $f$ on a finite open interval $(a, b)$ can be drawn from the behavior of $f(x)$ as $x \to a^+$ and as $x \to b^-$ (Table 4.4.3). Similar conclusions can be drawn for intervals of the form $(-\infty, b)$ or $(a, +\infty)$.

**Table 4.4.3**

ABSOLUTE EXTREMA ON OPEN INTERVALS

| | | | | |
|---|---|---|---|---|
| **LIMITS** | $\lim_{x\to a^+} f(x) = +\infty$<br>$\lim_{x\to b^-} f(x) = +\infty$ | $\lim_{x\to a^+} f(x) = -\infty$<br>$\lim_{x\to b^-} f(x) = -\infty$ | $\lim_{x\to a^+} f(x) = -\infty$<br>$\lim_{x\to b^-} f(x) = +\infty$ | $\lim_{x\to a^+} f(x) = +\infty$<br>$\lim_{x\to b^-} f(x) = -\infty$ |
| **CONCLUSION IF $f$ IS CONTINUOUS ON $(a, b)$** | $f$ has an absolute minimum but no absolute maximum on $(a, b)$. | $f$ has an absolute maximum but no absolute minimum on $(a, b)$. | $f$ has neither an absolute maximum nor an absolute minimum on $(a, b)$. | $f$ has neither an absolute maximum nor an absolute minimum on $(a, b)$. |
| **GRAPH** |  |  |  |  |

**▶ Example 5** Determine whether the function

$$f(x) = \frac{1}{x^2 - x}$$

has any absolute extrema on the interval $(0, 1)$. If so, find them and state where they occur.

***Solution.*** Since $f$ is continuous on the interval $(0, 1)$ and

$$\lim_{x\to 0^+} f(x) = \lim_{x\to 0^+} \frac{1}{x^2 - x} = \lim_{x\to 0^+} \frac{1}{x(x-1)} = -\infty$$

$$\lim_{x\to 1^-} f(x) = \lim_{x\to 1^-} \frac{1}{x^2 - x} = \lim_{x\to 1^-} \frac{1}{x(x-1)} = -\infty$$

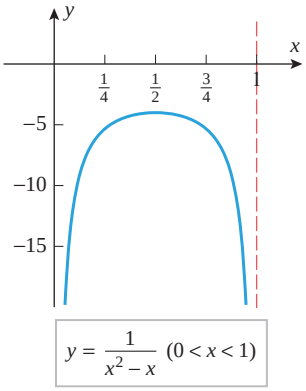
the function $f$ has an absolute maximum but no absolute minimum on the interval $(0, 1)$. By Theorem 4.4.3 the absolute maximum must occur at a critical point of $f$ in the interval $(0, 1)$. We have

$$f'(x) = -\frac{2x - 1}{(x^2 - x)^2}$$

so the only solution of the equation $f'(x) = 0$ is $x = \frac{1}{2}$. Although $f$ is not differentiable at $x = 0$ or at $x = 1$, these values are doubly disqualified since they are neither in the domain of $f$ nor in the interval $(0, 1)$. Thus, the absolute maximum occurs at $x = \frac{1}{2}$, and this absolute maximum is

$$f\left(\tfrac{1}{2}\right) = \frac{1}{\left(\tfrac{1}{2}\right)^2 - \tfrac{1}{2}} = -4$$

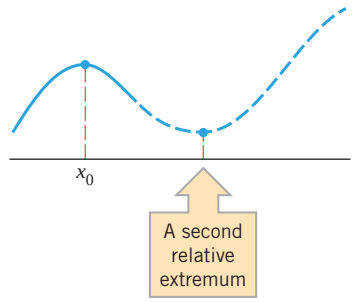
(Figure 4.4.5). ◀



▲ **Figure 4.4.5**

## ABSOLUTE EXTREMA OF FUNCTIONS WITH ONE RELATIVE EXTREMUM

If a continuous function has only one relative extremum on a finite or infinite interval, then that relative extremum must of necessity also be an absolute extremum. To understand why



▲ Figure 4.4.6

this is so, suppose that $f$ has a relative maximum at $x_0$ in an interval, and there are no other relative extrema of $f$ on the interval. If $f(x_0)$ is *not* the absolute maximum of $f$ on the interval, then the graph of $f$ has to make an upward turn somewhere on the interval to rise above $f(x_0)$. However, this cannot happen because in the process of making an upward turn it would produce a second relative extremum (Figure 4.4.6). Thus, $f(x_0)$ must be the absolute maximum as well as a relative maximum. This idea is captured in the following theorem, which we state without proof.

**4.4.4 THEOREM** *Suppose that $f$ is continuous and has exactly one relative extremum on an interval, say at $x_0$.*

(*a*) *If $f$ has a relative minimum at $x_0$, then $f(x_0)$ is the absolute minimum of $f$ on the interval.*

(*b*) *If $f$ has a relative maximum at $x_0$, then $f(x_0)$ is the absolute maximum of $f$ the interval.*

This theorem is often helpful in situations where other methods are difficult or tedious to apply.

▶ **Example 6** Find the absolute extrema, if any, of the function $f(x) = e^{(x^3-3x^2)}$ on the interval $(0, +\infty)$.

***Solution.*** We have

$$\lim_{x\to+\infty} f(x) = +\infty$$

(verify), so $f$ does not have an absolute maximum on the interval $(0, +\infty)$. However, the continuity of $f$ together with the fact that

$$\lim_{x\to 0^+} f(x) = e^0 = 1$$

is finite allow for the possibility that $f$ has an absolute minimum on $(0, +\infty)$. If so, it would have to occur at a critical point of $f$, so we consider

$$f'(x) = e^{(x^3-3x^2)}(3x^2 - 6x) = 3x(x-2)e^{(x^3-3x^2)}$$

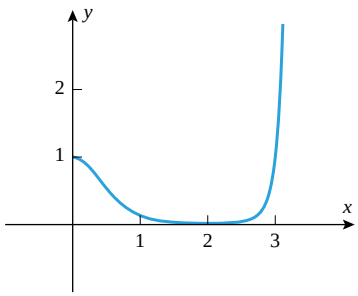
Since $e^{(x^3-3x^2)} > 0$ for all values of $x$, we see that $x = 0$ and $x = 2$ are the only critical points of $f$. Of these, only $x = 2$ is in the interval $(0, +\infty)$, so this is the point at which an absolute minimum could occur. To see whether an absolute minimum actually does occur at this point, we can apply part (*a*) of Theorem 4.4.4. Since

$$f''(x) = e^{(x^3-3x^2)}(3x^2 - 6x)^2 + e^{(x^3-3x^2)}(6x - 6)$$
$$= [(3x^2 - 6x)^2 + (6x - 6)]e^{(x^3-3x^2)}$$

we have

$$f''(2) = (0 + 6)e^{-4} = 6e^{-4} > 0$$

so a relative minimum occurs at $x = 2$ by the second derivative test. Thus, $f(x)$ has an absolute minimum at $x = 2$, and this absolute minimum is $f(2) = e^{-4} \approx 0.0183$ (Figure 4.4.7). ◀

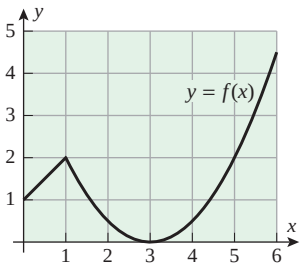


▲ Figure 4.4.7

Does the function in Example 6 have an absolute minimum on the interval $(-\infty, +\infty)$?

## ✔ QUICK CHECK EXERCISES 4.4 (See page 274 for answers.)

**1.** Use the accompanying graph to find the $x$-coordinates of the relative extrema and absolute extrema of $f$ on $[0, 6]$.



◀ **Figure Ex-1**

C **51.** Show that the absolute minimum value of

$$f(x) = x^2 + \frac{x^2}{(8 - x)^2}, \quad x > 8$$

occurs at $x = 10$ by using a CAS to find $f'(x)$ and to solve the equation $f'(x) = 0$.

**52.** The concentration $C(t)$ of a drug in the bloodstream $t$ hours after it has been injected is commonly modeled by an equation of the form

$$C(t) = \frac{K(e^{-bt} - e^{-at})}{a - b}$$

where $K > 0$ and $a > b > 0$.

(a) At what time does the maximum concentration occur?

(b) Let $K = 1$ for simplicity, and use a graphing utility to check your result in part (a) by graphing $C(t)$ for various values of $a$ and $b$.

**53.** Suppose that the equations of motion of a paper airplane during the first 12 seconds of flight are

$$x = t - 2\sin t, \quad y = 2 - 2\cos t \qquad (0 \leq t \leq 12)$$

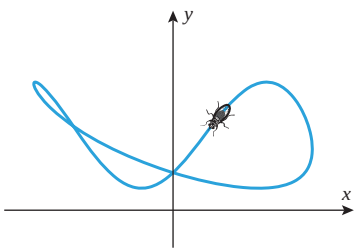
What are the highest and lowest points in the trajectory, and when is the airplane at those points?

**54.** The accompanying figure shows the path of a fly whose equations of motion are

$$x = \frac{\cos t}{2 + \sin t}, \quad y = 3 + \sin(2t) - 2\sin^2 t \qquad (0 \leq t \leq 2\pi)$$

(a) How high and low does it fly?

(b) How far left and right of the origin does it fly?



◀ Figure Ex-54

**55.** Let $f(x) = ax^2 + bx + c$, where $a > 0$. Prove that $f(x) \geq 0$ for all $x$ if and only if $b^2 - 4ac \leq 0$. [*Hint:* Find the minimum of $f(x)$.]

**56.** Prove Theorem 4.4.3 in the case where the extreme value is a minimum.

**57.** **Writing** Suppose that $f$ is continuous and positive-valued everywhere and that the $x$-axis is an asymptote for the graph of $f$, both as $x \to -\infty$ and as $x \to +\infty$. Explain why $f$ cannot have an absolute minimum but may have a relative minimum.

**58.** **Writing** Explain the difference between a relative maximum and an absolute maximum. Sketch a graph that illustrates a function with a relative maximum that is not an absolute maximum, and sketch another graph illustrating an absolute maximum that is not a relative maximum. Explain how these graphs satisfy the given conditions.

### ✔ QUICK CHECK ANSWERS 4.4

**1.** There is a relative minimum at $x = 3$, a relative maximum at $x = 1$, an absolute minimum at $x = 3$, and an absolute maximum at $x = 6$. **2.** (a) max, 6064; min, 2293 (b) max, 2400; min, 0 (c) max, 6064; min, $-1333$ (d) no max; min, $-1333$ **3.** (a) max, $f(0) = 25$; min, $f(3) = -2$ (b) max, $f(-1) = 30$; min, $f(3) = -2$ (c) max, $f(-1) = 30$; min, $f(-4) = -51$ (d) max, $f(10) = 635$; min, $f(-5) = -130$ (e) max, $f(-1) = 30$; no min

## 4.5 APPLIED MAXIMUM AND MIMIMUM PROBLEMS

*In this section we will show how the methods discussed in the last section can be used to solve various applied optimization problems.*

### CLASSIFICATION OF OPTIMIZATION PROBLEMS

The applied optimization problems that we will consider in this section fall into the following two categories:

- Problems that reduce to maximizing or minimizing a continuous function over a finite closed interval.
- Problems that reduce to maximizing or minimizing a continuous function over an infinite interval or a finite interval that is not closed.

For problems of the first type the Extreme-Value Theorem (4.4.2) guarantees that the problem has a solution, and we know that the solution can be obtained by examining the values of the function at the critical points and at the endpoints. However, for problems of the second type there may or may not be a solution. If the function is continuous and has exactly one relative extremum of the appropriate type on the interval, then Theorem 4.4.4 guarantees the existence of a solution and provides a method for finding it. In cases where this theorem is not applicable some ingenuity may be required to solve the problem.

### PROBLEMS INVOLVING FINITE CLOSED INTERVALS

In his *On a Method for the Evaluation of Maxima and Minima*, the seventeenth century French mathematician Pierre de Fermat solved an optimization problem very similar to the one posed in our first example. Fermat's work on such optimization problems prompted the French mathematician Laplace to proclaim Fermat the "true inventor of the differential calculus." Although this honor must still reside with Newton and Leibniz, it is the case that Fermat developed procedures that anticipated parts of differential calculus.

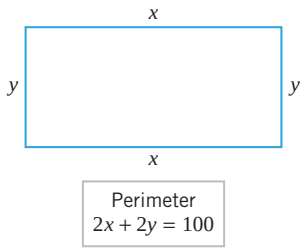
▶ **Example 1** A garden is to be laid out in a rectangular area and protected by a chicken wire fence. What is the largest possible area of the garden if only 100 running feet of chicken wire is available for the fence?

***Solution.*** Let

$$x = \text{length of the rectangle (ft)}$$
$$y = \text{width of the rectangle (ft)}$$
$$A = \text{area of the rectangle (ft}^2\text{)}$$

Then

$$A = xy \tag{1}$$



▲ **Figure 4.5.1**

Since the perimeter of the rectangle is 100 ft, the variables $x$ and $y$ are related by the equation

$$2x + 2y = 100 \quad \text{or} \quad y = 50 - x \tag{2}$$

(See Figure 4.5.1.) Substituting (2) in (1) yields

$$A = x(50 - x) = 50x - x^2 \tag{3}$$

Because $x$ represents a length, it cannot be negative, and because the two sides of length $x$ cannot have a combined length exceeding the total perimeter of 100 ft, the variable $x$ must satisfy

$$0 \le x \le 50 \tag{4}$$

Thus, we have reduced the problem to that of finding the value (or values) of $x$ in $[0, 50]$, for which $A$ is maximum. Since $A$ is a polynomial in $x$, it is continuous on $[0, 50]$, and so the maximum must occur at an endpoint of this interval or at a critical point.

From (3) we obtain

$$\frac{dA}{dx} = 50 - 2x$$

Setting $dA/dx = 0$ we obtain

$$50 - 2x = 0$$

**Pierre de Fermat (1601–1665)** Fermat, the son of a successful French leather merchant, was a lawyer who practiced mathematics as a hobby. He received a Bachelor of Civil Laws degree from the University of Orleans in 1631 and subsequently held various government positions, including a post as councillor to the Toulouse parliament. Although he was apparently financially successful, confidential documents of that time suggest that his performance in office and as a lawyer was poor, perhaps because he devoted so much time to mathematics. Throughout his life, Fermat fought all efforts to have his mathematical results published. He had the unfortunate habit of scribbling his work in the margins of books and often sent his results to friends without keeping copies for himself. As a result, he never received credit for many major achievements until his name was raised from obscurity in the mid-nineteenth century. It is now known that Fermat, simultaneously and independently of Descartes, developed analytic geometry. Unfortunately, Descartes and Fermat argued bitterly over various problems so that there was never any real cooperation between these two great geniuses.

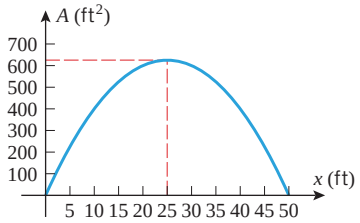
Fermat solved many fundamental calculus problems. He obtained the first procedure for differentiating polynomials, and solved many important maximization, minimization, area, and tangent problems. His work served to inspire Isaac Newton. Fermat is best known for his work in number theory, the study of properties of and relationships between whole numbers. He was the first mathematician to make substantial contributions to this field after the ancient Greek mathematician Diophantus. Unfortunately, none of Fermat's contemporaries appreciated his work in this area, a fact that eventually pushed Fermat into isolation and obscurity in later life. In addition to his work in calculus and number theory, Fermat was one of the founders of probability theory and made major contributions to the theory of optics. Outside mathematics, Fermat was a classical scholar of some note, was fluent in French, Italian, Spanish, Latin, and Greek, and he composed a considerable amount of Latin poetry.

One of the great mysteries of mathematics is shrouded in Fermat's work in number theory. In the margin of a book by Diophantus, Fermat scribbled that for integer values of $n$ greater than 2, the equation $x^n + y^n = z^n$ has no nonzero integer solutions for $x$, $y$, and $z$. He stated, "I have discovered a truly marvelous proof of this, which however the margin is not large enough to contain." This result, which became known as "Fermat's last theorem," appeared to be true, but its proof evaded the greatest mathematical geniuses for 300 years until Professor Andrew Wiles of Princeton University presented a proof in June 1993 in a dramatic series of three lectures that drew international media attention (see *New York Times*, June 27, 1993). As it turned out, that proof had a serious gap that Wiles and Richard Taylor fixed and published in 1995. A prize of 100,000 German marks was offered in 1908 for the solution, but it is worthless today because of inflation.

[*Image: http://en.wikipedia.org/wiki/File:Pierre_de_Fermat.png*]

**Table 4.5.1**

| $x$ | 0 | 25 | 50 |
|---|---|---|---|
| $A$ | 0 | 625 | 0 |



▲ **Figure 4.5.2**

In Example 1 we included $x = 0$ and $x = 50$ as possible values of $x$, even though these correspond to rectangles with two sides of length zero. If we view this as a purely mathematical problem, then there is nothing wrong with this. However, if we view this as an applied problem in which the rectangle will be formed from physical material, then it would make sense to exclude these values.

or $x = 25$. Thus, the maximum occurs at one of the values

$$x = 0, \quad x = 25, \quad x = 50$$

Substituting these values in (3) yields Table 4.5.1, which tells us that the maximum area of 625 ft$^2$ occurs at $x = 25$, which is consistent with the graph of (3) in Figure 4.5.2. From (2) the corresponding value of $y$ is 25, so the rectangle of perimeter 100 ft with greatest area is a square with sides of length 25 ft. ◀

Example 1 illustrates the following five-step procedure that can be used for solving many applied maximum and minimum problems.

***A Procedure for Solving Applied Maximum and Minimum Problems***

**Step 1.** Draw an appropriate figure and label the quantities relevant to the problem.

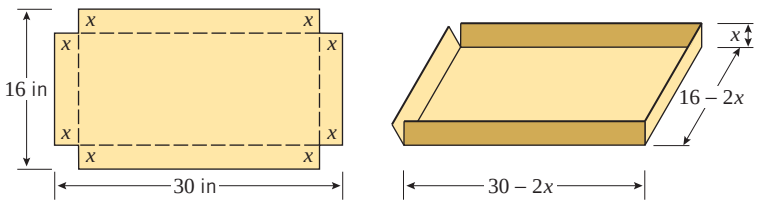
**Step 2.** Find a formula for the quantity to be maximized or minimized.

**Step 3.** Using the conditions stated in the problem to eliminate variables, express the quantity to be maximized or minimized as a function of one variable.

**Step 4.** Find the interval of possible values for this variable from the physical restrictions in the problem.

**Step 5.** If applicable, use the techniques of the preceding section to obtain the maximum or minimum.

▶ **Example 2** An open box is to be made from a 16-inch by 30-inch piece of cardboard by cutting out squares of equal size from the four corners and bending up the sides (Figure 4.5.3). What size should the squares be to obtain a box with the largest volume?



▶ **Figure 4.5.3** (*a*) (*b*)

***Solution.*** For emphasis, we explicitly list the steps of the five-step problem-solving procedure given above as an outline for the solution of this problem. (In later examples we will follow these guidelines without listing the steps.)

- *Step 1:* Figure 4.5.3*a* illustrates the cardboard piece with squares removed from its corners. Let

  $x$ = length (in inches) of the sides of the squares to be cut out

  $V$ = volume (in cubic inches) of the resulting box

- *Step 2:* Because we are removing a square of side $x$ from each corner, the resulting box will have dimensions $16 - 2x$ by $30 - 2x$ by $x$ (Figure 4.5.3*b*). Since the volume of a box is the product of its dimensions, we have

$$V = (16 - 2x)(30 - 2x)x = 480x - 92x^2 + 4x^3 \tag{5}$$

- *Step 3:* Note that our volume expression is already in terms of the single variable $x$.
- *Step 4:* The variable $x$ in (5) is subject to certain restrictions. Because $x$ represents a length, it cannot be negative, and because the width of the cardboard is 16 inches, we cannot cut out squares whose sides are more than 8 inches long. Thus, the variable $x$ in (5) must satisfy

$$0 \le x \le 8$$

and hence we have reduced our problem to finding the value (or values) of $x$ in the interval $[0, 8]$ for which (5) is a maximum.

- *Step 5:* From (5) we obtain

$$\frac{dV}{dx} = 480 - 184x + 12x^2 = 4(120 - 46x + 3x^2)$$
$$= 4(x - 12)(3x - 10)$$

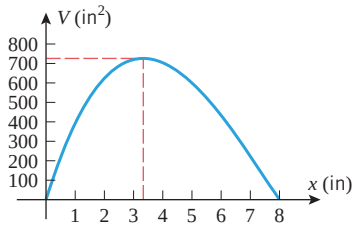
Setting $dV/dx = 0$ yields

$$x = \tfrac{10}{3} \quad \text{and} \quad x = 12$$

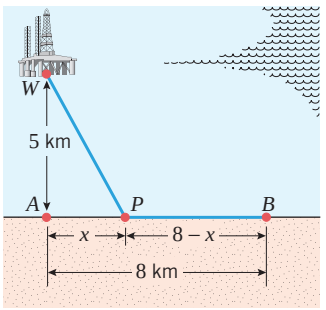
Since $x = 12$ falls outside the interval $[0, 8]$, the maximum value of $V$ occurs either at the critical point $x = \frac{10}{3}$ or at the endpoints $x = 0$, $x = 8$. Substituting these values into (5) yields Table 4.5.2, which tells us that the greatest possible volume $V = \frac{19{,}600}{27}$ in$^3$ $\approx 726$ in$^3$ occurs when we cut out squares whose sides have length $\frac{10}{3}$ inches. This is consistent with the graph of (5) shown in Figure 4.5.4. ◀

**Table 4.5.2**

| $x$ | 0 | $\frac{10}{3}$ | 8 |
|---|---|---|---|
| $V$ | 0 | $\frac{19{,}600}{27} \approx 726$ | 0 |



▲ **Figure 4.5.4**



▲ **Figure 4.5.5**

▶ **Example 3** Figure 4.5.5 shows an offshore oil well located at a point $W$ that is 5 km from the closest point $A$ on a straight shoreline. Oil is to be piped from $W$ to a shore point $B$ that is 8 km from $A$ by piping it on a straight line under water from $W$ to some shore point $P$ between $A$ and $B$ and then on to $B$ via pipe along the shoreline. If the cost of laying pipe is \$1,000,000/km under water and \$500,000/km over land, where should the point $P$ be located to minimize the cost of laying the pipe?

***Solution.*** Let

$x$ = distance (in kilometers) between $A$ and $P$

$c$ = cost (in millions of dollars) for the entire pipeline

From Figure 4.5.5 the length of pipe under water is the distance between $W$ and $P$. By the Theorem of Pythagoras that length is

$$\sqrt{x^2 + 25} \tag{6}$$

Also from Figure 4.5.5, the length of pipe over land is the distance between $P$ and $B$, which is

$$8 - x \tag{7}$$

From (6) and (7) it follows that the total cost $c$ (in millions of dollars) for the pipeline is

$$c = 1(\sqrt{x^2 + 25}) + \tfrac{1}{2}(8 - x) = \sqrt{x^2 + 25} + \tfrac{1}{2}(8 - x) \tag{8}$$

Because the distance between $A$ and $B$ is 8 km, the distance $x$ between $A$ and $P$ must satisfy

$$0 \le x \le 8$$

We have thus reduced our problem to finding the value (or values) of $x$ in the interval $[0, 8]$ for which $c$ is a minimum. Since $c$ is a continuous function of $x$ on the closed interval $[0, 8]$, we can use the methods developed in the preceding section to find the minimum.

From (8) we obtain

$$\frac{dc}{dx} = \frac{x}{\sqrt{x^2 + 25}} - \frac{1}{2}$$

Setting $dc/dx = 0$ and solving for $x$ yields

$$\frac{x}{\sqrt{x^2 + 25}} = \frac{1}{2} \tag{9}$$

$$x^2 = \frac{1}{4}(x^2 + 25)$$

$$x = \pm\frac{5}{\sqrt{3}}$$

**TECHNOLOGY MASTERY**

If you have a CAS, use it to check all of the computations in Example 3. Specifically, differentiate $c$ with respect to $x$, solve the equation $dc/dx = 0$, and perform all of the numerical calculations.

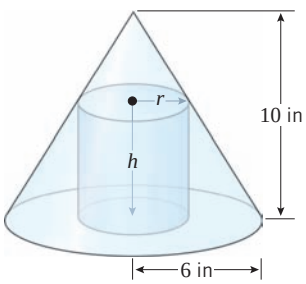
The number $-5/\sqrt{3}$ is not a solution of (9) and must be discarded, leaving $x = 5/\sqrt{3}$ as the only critical point. Since this point lies in the interval [0, 8], the minimum must occur at one of the values

$$x = 0, \quad x = 5/\sqrt{3}, \quad x = 8$$

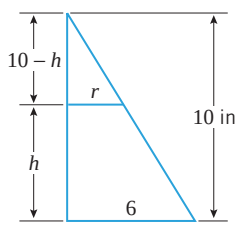
Substituting these values into (8) yields Table 4.5.3, which tells us that the least possible cost of the pipeline (to the nearest dollar) is $c = \$8{,}330{,}127$, and this occurs when the point $P$ is located at a distance of $5/\sqrt{3} \approx 2.89$ km from $A$. ◀

**Table 4.5.3**

| $x$ | 0 | $\frac{5}{\sqrt{3}}$ | 8 |
|---|---|---|---|
| $c$ | 9 | $\frac{10}{\sqrt{3}} + \left(4 - \frac{5}{2\sqrt{3}}\right) \approx 8.330127$ | $\sqrt{89} \approx 9.433981$ |



(a)



(b)

▲ Figure 4.5.6

▶ **Example 4** Find the radius and height of the right circular cylinder of largest volume that can be inscribed in a right circular cone with radius 6 inches and height 10 inches (Figure 4.5.6*a*).

***Solution.*** Let

$r$ = radius (in inches) of the cylinder
$h$ = height (in inches) of the cylinder
$V$ = volume (in cubic inches) of the cylinder

The formula for the volume of the inscribed cylinder is

$$V = \pi r^2 h \tag{10}$$

To eliminate one of the variables in (10) we need a relationship between $r$ and $h$. Using similar triangles (Figure 4.5.6*b*) we obtain

$$\frac{10 - h}{r} = \frac{10}{6} \quad \text{or} \quad h = 10 - \frac{5}{3}r \tag{11}$$

Substituting (11) into (10) we obtain

$$V = \pi r^2\left(10 - \frac{5}{3}r\right) = 10\pi r^2 - \frac{5}{3}\pi r^3 \tag{12}$$

which expresses $V$ in terms of $r$ alone. Because $r$ represents a radius, it cannot be negative, and because the radius of the inscribed cylinder cannot exceed the radius of the cone, the variable $r$ must satisfy

$$0 \le r \le 6$$

Thus, we have reduced the problem to that of finding the value (or values) of $r$ in $[0, 6]$ for which (12) is a maximum. Since $V$ is a continuous function of $r$ on $[0, 6]$, the methods developed in the preceding section apply.

From (12) we obtain

$$\frac{dV}{dr} = 20\pi r - 5\pi r^2 = 5\pi r(4 - r)$$

Setting $dV/dr = 0$ gives

$$5\pi r(4 - r) = 0$$

so $r = 0$ and $r = 4$ are critical points. Since these lie in the interval $[0, 6]$, the maximum must occur at one of the values

$$r = 0, \quad r = 4, \quad r = 6$$

**Table 4.5.4**

| $r$ | 0 | 4 | 6 |
|---|---|---|---|
| $V$ | 0 | $\frac{160}{3}\pi$ | 0 |

Substituting these values into (12) yields Table 4.5.4, which tells us that the maximum volume $V = \frac{160}{3}\pi \approx 168$ in$^3$ occurs when the inscribed cylinder has radius 4 in. When $r = 4$ it follows from (11) that $h = \frac{10}{3}$. Thus, the inscribed cylinder of largest volume has radius $r = 4$ in and height $h = \frac{10}{3}$ in. ◀

## PROBLEMS INVOLVING INTERVALS THAT ARE NOT BOTH FINITE AND CLOSED

▶ **Example 5** A closed cylindrical can is to hold 1 liter (1000 cm$^3$) of liquid. How should we choose the height and radius to minimize the amount of material needed to manufacture the can?

***Solution.*** Let

$h$ = height (in cm) of the can

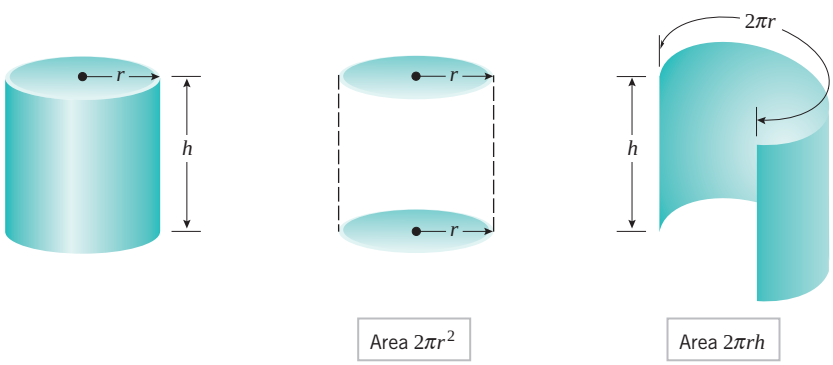
$r$ = radius (in cm) of the can

$S$ = surface area (in cm$^2$) of the can

Assuming there is no waste or overlap, the amount of material needed for manufacture will be the same as the surface area of the can. Since the can consists of two circular disks of radius $r$ and a rectangular sheet with dimensions $h$ by $2\pi r$ (Figure 4.5.7), the surface area will be

$$S = 2\pi r^2 + 2\pi r h \tag{13}$$

Since $S$ depends on two variables, $r$ and $h$, we will look for some condition in the problem that will allow us to express one of these variables in terms of the other. For this purpose,



▲ **Figure 4.5.7**

observe that the volume of the can is 1000 $cm^3$, so it follows from the formula $V = \pi r^2 h$ for the volume of a cylinder that

$$1000 = \pi r^2 h \quad \text{or} \quad h = \frac{1000}{\pi r^2} \tag{14–15}$$

Substituting (15) in (13) yields

$$S = 2\pi r^2 + \frac{2000}{r} \tag{16}$$

Thus, we have reduced the problem to finding a value of $r$ in the interval $(0, +\infty)$ for which $S$ is minimum. Since $S$ is a continuous function of $r$ on the interval $(0, +\infty)$ and

$$\lim_{r \to 0^+} \left(2\pi r^2 + \frac{2000}{r}\right) = +\infty \quad \text{and} \quad \lim_{r \to +\infty} \left(2\pi r^2 + \frac{2000}{r}\right) = +\infty$$

the analysis in Table 4.4.3 implies that $S$ does have a minimum on the interval $(0, +\infty)$. Since this minimum must occur at a critical point, we calculate

$$\frac{dS}{dr} = 4\pi r - \frac{2000}{r^2} \tag{17}$$

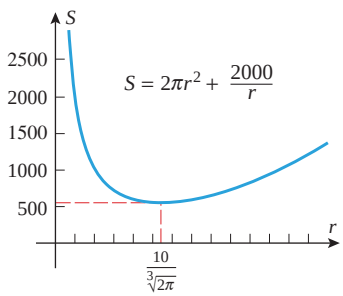
Setting $dS/dr = 0$ gives

$$r = \frac{10}{\sqrt[3]{2\pi}} \approx 5.4 \tag{18}$$

Since (18) is the only critical point in the interval $(0, +\infty)$, this value of $r$ yields the minimum value of $S$. From (15) the value of $h$ corresponding to this $r$ is

$$h = \frac{1000}{\pi(10/\sqrt[3]{2\pi})^2} = \frac{20}{\sqrt[3]{2\pi}} = 2r$$

It is not an accident here that the minimum occurs when the height of the can is equal to the diameter of its base (Exercise 29).



▲ Figure 4.5.8

***Second Solution.*** The conclusion that a minimum occurs at the value of $r$ in (18) can be deduced from Theorem 4.4.4 and the second derivative test by noting that

$$\frac{d^2S}{dr^2} = 4\pi + \frac{4000}{r^3}$$

is positive if $r > 0$ and hence is positive if $r = 10/\sqrt[3]{2\pi}$. This implies that a relative minimum, and therefore a minimum, occurs at the critical point $r = 10/\sqrt[3]{2\pi}$.

***Third Solution.*** An alternative justification that the critical point $r = 10/\sqrt[3]{2\pi}$ corresponds to a minimum for $S$ is to view the graph of $S$ versus $r$ (Figure 4.5.8). ◄

In Example 5, the surface area $S$ has no absolute maximum, since $S$ increases without bound as the radius $r$ approaches 0 (Figure 4.5.8). Thus, had we asked for the dimensions of the can requiring the *maximum* amount of material for its manufacture, there would have been no solution to the problem. Optimization problems with no solution are sometimes called *ill posed*.

► **Example 6** Find a point on the curve $y = x^2$ that is closest to the point $(18, 0)$.

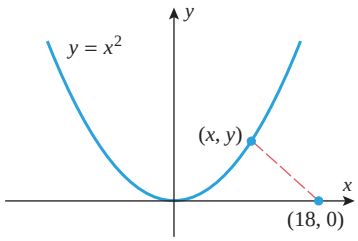
***Solution.*** The distance $L$ between $(18, 0)$ and an arbitrary point $(x, y)$ on the curve $y = x^2$ (Figure 4.5.9) is given by

$$L = \sqrt{(x - 18)^2 + (y - 0)^2}$$

Since $(x, y)$ lies on the curve, $x$ and $y$ satisfy $y = x^2$; thus,

$$L = \sqrt{(x - 18)^2 + x^4} \tag{19}$$

Because there are no restrictions on $x$, the problem reduces to finding a value of $x$ in $(-\infty, +\infty)$ for which (19) is a minimum. The distance $L$ and the square of the distance $L^2$



▲ Figure 4.5.9

are minimized at the same value (see Exercise 68). Thus, the minimum value of $L$ in (19) and the minimum value of

$$S = L^2 = (x - 18)^2 + x^4 \tag{20}$$

occur at the same $x$-value.

From (20),

$$\frac{dS}{dx} = 2(x - 18) + 4x^3 = 4x^3 + 2x - 36 \tag{21}$$

so the critical points satisfy $4x^3 + 2x - 36 = 0$ or, equivalently,

$$2x^3 + x - 18 = 0 \tag{22}$$

To solve for $x$ we will begin by checking the divisors of $-18$ to see whether the polynomial on the left side has any integer roots (see Appendix C). These divisors are $\pm 1$, $\pm 2$, $\pm 3$, $\pm 6$, $\pm 9$, and $\pm 18$. A check of these values shows that $x = 2$ is a root, so $x - 2$ is a factor of the polynomial. After dividing the polynomial by this factor we can rewrite (22) as

$$(x - 2)(2x^2 + 4x + 9) = 0$$

Thus, the remaining solutions of (22) satisfy the quadratic equation

$$2x^2 + 4x + 9 = 0$$

But this equation has no real solutions (using the quadratic formula), so $x = 2$ is the only critical point of $S$. To determine the nature of this critical point we will use the second derivative test. From (21),

$$\frac{d^2S}{dx^2} = 12x^2 + 2, \quad \text{so} \quad \left.\frac{d^2S}{dx^2}\right|_{x=2} = 50 > 0$$

which shows that a relative minimum occurs at $x = 2$. Since $x = 2$ yields the only relative extremum for $L$, it follows from Theorem 4.4.4 that an absolute minimum value of $L$ also occurs at $x = 2$. Thus, the point on the curve $y = x^2$ closest to (18, 0) is

$$(x, y) = (x, x^2) = (2, 4) \quad ◀$$

## AN APPLICATION TO ECONOMICS

Three functions of importance to an economist or a manufacturer are

$C(x)$ = total cost of producing $x$ units of a product during some time period

$R(x)$ = total revenue from selling $x$ units of the product during the time period

$P(x)$ = total profit obtained by selling $x$ units of the product during the time period

These are called, respectively, the ***cost function***, ***revenue function***, and ***profit function***. If all units produced are sold, then these are related by

$$P(x) = R(x) - C(x) \tag{23}$$
$$\text{[profit]} = \text{[revenue]} - \text{[cost]}$$

The total cost $C(x)$ of producing $x$ units can be expressed as a sum

$$C(x) = a + M(x) \tag{24}$$

where $a$ is a constant, called ***overhead***, and $M(x)$ is a function representing ***manufacturing cost***. The overhead, which includes such fixed costs as rent and insurance, does not depend on $x$; it must be paid even if nothing is produced. On the other hand, the manufacturing cost $M(x)$, which includes such items as cost of materials and labor, depends on the number of items manufactured. It is shown in economics that with suitable simplifying assumptions, $M(x)$ can be expressed in the form

$$M(x) = bx + cx^2$$

where $b$ and $c$ are constants. Substituting this in (24) yields

$$C(x) = a + bx + cx^2 \tag{25}$$

If a manufacturing firm can sell all the items it produces for $p$ dollars apiece, then its total revenue $R(x)$ (in dollars) will be

$$R(x) = px \tag{26}$$

and its total profit $P(x)$ (in dollars) will be

$$P(x) = [\text{total revenue}] - [\text{total cost}] = R(x) - C(x) = px - C(x)$$

Thus, if the cost function is given by (25),

$$P(x) = px - (a + bx + cx^2) \tag{27}$$

Depending on such factors as number of employees, amount of machinery available, economic conditions, and competition, there will be some upper limit $l$ on the number of items a manufacturer is capable of producing and selling. Thus, during a fixed time period the variable $x$ in (27) will satisfy

$$0 \le x \le l$$

By determining the value or values of $x$ in $[0, l]$ that maximize (27), the firm can determine how many units of its product must be manufactured and sold to yield the greatest profit. This is illustrated in the following numerical example.

Jim Karageorge/Getty Images

*A pharmaceutical firm's profit is a function of the number of units produced.*

▶ **Example 7** A liquid form of antibiotic manufactured by a pharmaceutical firm is sold in bulk at a price of \$200 per unit. If the total production cost (in dollars) for $x$ units is

$$C(x) = 500{,}000 + 80x + 0.003x^2$$

and if the production capacity of the firm is at most 30,000 units in a specified time, how many units of antibiotic must be manufactured and sold in that time to maximize the profit?

***Solution.*** Since the total revenue for selling $x$ units is $R(x) = 200x$, the profit $P(x)$ on $x$ units will be

$$P(x) = R(x) - C(x) = 200x - (500{,}000 + 80x + 0.003x^2) \tag{28}$$

Since the production capacity is at most 30,000 units, $x$ must lie in the interval [0, 30,000]. From (28)

$$\frac{dP}{dx} = 200 - (80 + 0.006x) = 120 - 0.006x$$

Setting $dP/dx = 0$ gives

$$120 - 0.006x = 0 \quad \text{or} \quad x = 20{,}000$$

Since this critical point lies in the interval [0, 30,000], the maximum profit must occur at one of the values

$$x = 0, \quad x = 20{,}000, \quad \text{or} \quad x = 30{,}000$$

Substituting these values in (28) yields Table 4.5.5, which tells us that the maximum profit $P = \$700{,}000$ occurs when $x = 20{,}000$ units are manufactured and sold in the specified time. ◀

**Table 4.5.5**

| $x$ | 0 | 20,000 | 30,000 |
|---|---|---|---|
| $P(x)$ | −500,000 | 700,000 | 400,000 |

## MARGINAL ANALYSIS

Economists call $P'(x)$, $R'(x)$, and $C'(x)$ the ***marginal profit***, ***marginal revenue***, and ***marginal cost***, respectively; and they interpret these quantities as the *additional* profit, revenue, and cost that result from producing and selling one additional unit of the product when the production and sales levels are at $x$ units. These interpretations follow from the local linear approximations of the profit, revenue, and cost functions. For example, it follows from Formula (2) of Section 3.5 that when the production and sales levels are at $x$ units the local linear approximation of the profit function is

$$P(x + \Delta x) \approx P(x) + P'(x)\Delta x$$

Thus, if $\Delta x = 1$ (one additional unit produced and sold), this formula implies

$$P(x + 1) \approx P(x) + P'(x)$$

and hence the *additional* profit that results from producing and selling one additional unit can be approximated as

$$P(x + 1) - P(x) \approx P'(x)$$

Similarly, $R(x + 1) - R(x) \approx R'(x)$ and $C(x + 1) - C(x) \approx C'(x)$.

## A BASIC PRINCIPLE OF ECONOMICS

It follows from (23) that $P'(x) = 0$ has the same solution as $C'(x) = R'(x)$, and this implies that the maximum profit must occur at a point where the marginal revenue is equal to the marginal cost; that is:

*If profit is maximum, then the cost of manufacturing and selling an additional unit of a product is approximately equal to the revenue generated by the additional unit.*

In Example 7, the maximum profit occurs when $x = 20{,}000$ units. Note that

$$C(20{,}001) - C(20{,}000) = \$200.003 \quad \text{and} \quad R(20{,}001) - R(20{,}000) = \$200$$

which is consistent with this basic economic principle.

## ✔ QUICK CHECK EXERCISES 4.5

(See page 288 for answers.)

1. A positive number $x$ and its reciprocal are added together. The smallest possible value of this sum is obtained by minimizing $f(x) =$ _____ for $x$ in the interval _____.
2. Two nonnegative numbers, $x$ and $y$, have a sum equal to 10. The largest possible product of the two numbers is obtained by maximizing $f(x) =$ _____ for $x$ in the interval _____.
3. A rectangle in the $xy$-plane has one corner at the origin, an adjacent corner at the point $(x, 0)$, and a third corner at a point on the line segment from $(0, 4)$ to $(3, 0)$. The largest possible area of the rectangle is obtained by maximizing $A(x) =$ _____ for $x$ in the interval _____.
4. An open box is to be made from a 20-inch by 32-inch piece of cardboard by cutting out $x$-inch by $x$-inch squares from the four corners and bending up the sides. The largest possible volume of the box is obtained by maximizing $V(x) =$ _____ for $x$ in the interval _____.

## EXERCISE SET 4.5

1. Find a number in the closed interval $\left[\frac{1}{2}, \frac{3}{2}\right]$ such that the sum of the number and its reciprocal is
   (a) as small as possible
   (b) as large as possible.
2. How should two nonnegative numbers be chosen so that their sum is 1 and the sum of their squares is
   (a) as large as possible
   (b) as small as possible?

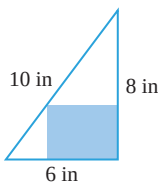
**3.** A rectangular field is to be bounded by a fence on three sides and by a straight stream on the fourth side. Find the dimensions of the field with maximum area that can be enclosed using 1000 ft of fence.

**4.** The boundary of a field is a right triangle with a straight stream along its hypotenuse and with fences along its other two sides. Find the dimensions of the field with maximum area that can be enclosed using 1000 ft of fence.

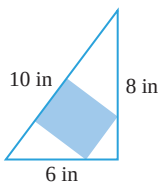
**5.** A rectangular plot of land is to be fenced in using two kinds of fencing. Two opposite sides will use heavy-duty fencing selling for \$3 a foot, while the remaining two sides will use standard fencing selling for \$2 a foot. What are the dimensions of the rectangular plot of greatest area that can be fenced in at a cost of \$6000?

**6.** A rectangle is to be inscribed in a right triangle having sides of length 6 in, 8 in, and 10 in. Find the dimensions of the rectangle with greatest area assuming the rectangle is positioned as in Figure Ex-6.

**7.** Solve the problem in Exercise 6 assuming the rectangle is positioned as in Figure Ex-7.



▲ **Figure Ex-6**



▲ **Figure Ex-7**

**8.** A rectangle has its two lower corners on the $x$-axis and its two upper corners on the curve $y = 16 - x^2$. For all such rectangles, what are the dimensions of the one with largest area?

**9.** Find the dimensions of the rectangle with maximum area that can be inscribed in a circle of radius 10.

**10.** Find the point $P$ in the first quadrant on the curve $y = x^{-2}$ such that a rectangle with sides on the coordinate axes and a vertex at $P$ has the smallest possible perimeter.

**11.** A rectangular area of 3200 ft$^2$ is to be fenced off. Two opposite sides will use fencing costing \$1 per foot and the remaining sides will use fencing costing \$2 per foot. Find the dimensions of the rectangle of least cost.

**12.** Show that among all rectangles with perimeter $p$, the square has the maximum area.

**13.** Show that among all rectangles with area $A$, the square has the minimum perimeter.

**14.** A wire of length 12 in can be bent into a circle, bent into a square, or cut into two pieces to make both a circle and a square. How much wire should be used for the circle if the total area enclosed by the figure(s) is to be
(a) a maximum (b) a minimum?

**15.** A rectangle $R$ in the plane has corners at $(\pm 8, \pm 12)$, and a 100 by 100 square $S$ is positioned in the plane so that its sides are parallel to the coordinate axes and the lower left corner of $S$ is on the line $y = -3x$. What is the largest possible area of a region in the plane that is contained in both $R$ and $S$?

**16.** Solve the problem in Exercise 15 if $S$ is a 16 by 16 square.

**17.** Solve the problem in Exercise 15 if $S$ is positioned with its lower left corner on the line $y = -6x$.

**18.** A rectangular page is to contain 42 square inches of printable area. The margins at the top and bottom of the page are each 1 inch, one side margin is 1 inch, and the other side margin is 2 inches. What should the dimensions of the page be so that the least amount of paper is used?

**19.** A box with a square base is taller than it is wide. In order to send the box through the U.S. mail, the height of the box and the perimeter of the base can sum to no more than 108 in. What is the maximum volume for such a box?

**20.** A box with a square base is wider than it is tall. In order to send the box through the U.S. mail, the width of the box and the perimeter of one of the (nonsquare) sides of the box can sum to no more than 108 in. What is the maximum volume for such a box?

**21.** An open box is to be made from a 3 ft by 8 ft rectangular piece of sheet metal by cutting out squares of equal size from the four corners and bending up the sides. Find the maximum volume that the box can have.

**22.** A closed rectangular container with a square base is to have a volume of 2250 in$^3$. The material for the top and bottom of the container will cost \$2 per in$^2$, and the material for the sides will cost \$3 per in$^2$. Find the dimensions of the container of least cost.

**23.** A closed rectangular container with a square base is to have a volume of 2000 cm$^3$. It costs twice as much per square centimeter for the top and bottom as it does for the sides. Find the dimensions of the container of least cost.

**24.** A container with square base, vertical sides, and open top is to be made from 1000 ft$^2$ of material. Find the dimensions of the container with greatest volume.

**25.** A rectangular container with two square sides and an open top is to have a volume of $V$ cubic units. Find the dimensions of the container with minimum surface area.

**26.** A church window consisting of a rectangle topped by a semicircle is to have a perimeter $p$. Find the radius of the semicircle if the area of the window is to be maximum.

**27.** Find the dimensions of the right circular cylinder of largest volume that can be inscribed in a sphere of radius $R$.

**28.** Find the dimensions of the right circular cylinder of greatest surface area that can be inscribed in a sphere of radius $R$.

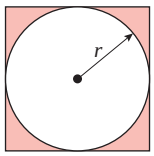
**29.** A closed, cylindrical can is to have a volume of $V$ cubic units. Show that the can of minimum surface area is achieved when the height is equal to the diameter of the base.

**30.** A closed cylindrical can is to have a surface area of $S$ square units. Show that the can of maximum volume is achieved when the height is equal to the diameter of the base.

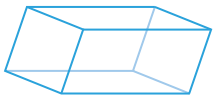
**31.** A cylindrical can, open at the top, is to hold 500 $\text{cm}^3$ of liquid. Find the height and radius that minimize the amount of material needed to manufacture the can.

**32.** A soup can in the shape of a right circular cylinder of radius $r$ and height $h$ is to have a prescribed volume $V$. The top and bottom are cut from squares as shown in Figure Ex-32. If the shaded corners are wasted, but there is no other waste, find the ratio $r/h$ for the can requiring the least material (including waste).

**33.** A box-shaped wire frame consists of two identical wire squares whose vertices are connected by four straight wires of equal length (Figure Ex-33). If the frame is to be made from a wire of length $L$, what should the dimensions be to obtain a box of greatest volume?



▲ **Figure Ex-32**



▲ **Figure Ex-33**

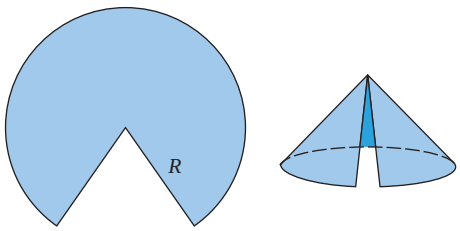
**34.** Suppose that the sum of the surface areas of a sphere and a cube is a constant.

(a) Show that the sum of their volumes is smallest when the diameter of the sphere is equal to the length of an edge of the cube.

(b) When will the sum of their volumes be greatest?

**35.** Find the height and radius of the cone of slant height $L$ whose volume is as large as possible.

**36.** A cone is made from a circular sheet of radius $R$ by cutting out a sector and gluing the cut edges of the remaining piece together (Figure Ex-36). What is the maximum volume attainable for the cone?



▲ **Figure Ex-36**

**37.** A cone-shaped paper drinking cup is to hold 100 $\text{cm}^3$ of water. Find the height and radius of the cup that will require the least amount of paper.

**38.** Find the dimensions of the isosceles triangle of least area that can be circumscribed about a circle of radius $R$.

**39.** Find the height and radius of the right circular cone with least volume that can be circumscribed about a sphere of radius $R$.

**40.** A commercial cattle ranch currently allows 20 steers per acre of grazing land; on the average its steers weigh 2000 lb at market. Estimates by the Agriculture Department indicate that the average market weight per steer will be reduced by 50 lb for each additional steer added per acre of grazing land. How many steers per acre should be allowed in order for the ranch to get the largest possible total market weight for its cattle?

**41.** A company mines low-grade nickel ore. If the company mines $x$ tons of ore, it can sell the ore for $p = 225 - 0.25x$ dollars per ton. Find the revenue and marginal revenue functions. At what level of production would the company obtain the maximum revenue?

**42.** A fertilizer producer finds that it can sell its product at a price of $p = 300 - 0.1x$ dollars per unit when it produces $x$ units of fertilizer. The total production cost (in dollars) for $x$ units is

$$C(x) = 15{,}000 + 125x + 0.025x^2$$

If the production capacity of the firm is at most 1000 units of fertilizer in a specified time, how many units must be manufactured and sold in that time to maximize the profit?

**43.** (a) A chemical manufacturer sells sulfuric acid in bulk at a price of \$100 per unit. If the daily total production cost in dollars for $x$ units is

$$C(x) = 100{,}000 + 50x + 0.0025x^2$$

and if the daily production capacity is at most 7000 units, how many units of sulfuric acid must be manufactured and sold daily to maximize the profit?

(b) Would it benefit the manufacturer to expand the daily production capacity?

(c) Use marginal analysis to approximate the effect on profit if daily production could be increased from 7000 to 7001 units.

**44.** A firm determines that $x$ units of its product can be sold daily at $p$ dollars per unit, where

$$x = 1000 - p$$

The cost of producing $x$ units per day is

$$C(x) = 3000 + 20x$$

(a) Find the revenue function $R(x)$.

(b) Find the profit function $P(x)$.

(c) Assuming that the production capacity is at most 500 units per day, determine how many units the company must produce and sell each day to maximize the profit.

(d) Find the maximum profit.

(e) What price per unit must be charged to obtain the maximum profit?

**45.** In a certain chemical manufacturing process, the daily weight $y$ of defective chemical output depends on the total weight $x$ of all output according to the empirical formula

$$y = 0.01x + 0.00003x^2$$

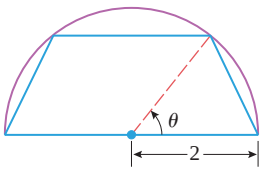
where $x$ and $y$ are in pounds. If the profit is \$100 per pound of nondefective chemical produced and the loss is \$20 per

pound of defective chemical produced, how many pounds of chemical should be produced daily to maximize the total daily profit?

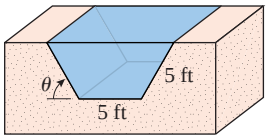
**46.** An independent truck driver charges a client \$15 for each hour of driving, plus the cost of fuel. At highway speeds of $v$ miles per hour, the trucker's rig gets $10 - 0.07v$ miles per gallon of diesel fuel. If diesel fuel costs \$2.50 per gallon, what speed $v$ will minimize the cost to the client?

**47.** A trapezoid is inscribed in a semicircle of radius 2 so that one side is along the diameter (Figure Ex-47). Find the maximum possible area for the trapezoid. [*Hint:* Express the area of the trapezoid in terms of $\theta$.]

**48.** A drainage channel is to be made so that its cross section is a trapezoid with equally sloping sides (Figure Ex-48). If the sides and bottom all have a length of 5 ft, how should the angle $\theta$ $(0 \le \theta \le \pi/2)$ be chosen to yield the greatest cross-sectional area of the channel?



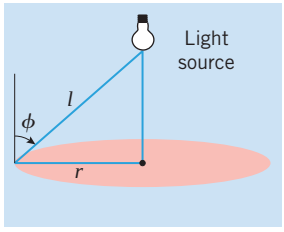
▲ **Figure Ex-47**



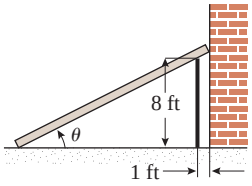
▲ **Figure Ex-48**

**49.** A lamp is suspended above the center of a round table of radius $r$. How high above the table should the lamp be placed to achieve maximum illumination at the edge of the table? [Assume that the illumination $I$ is directly proportional to the cosine of the angle of incidence $\phi$ of the light rays and inversely proportional to the square of the distance $l$ from the light source (Figure Ex-49).]

**50.** A plank is used to reach over a fence 8 ft high to support a wall that is 1 ft behind the fence (Figure Ex-50). What is the length of the shortest plank that can be used? [*Hint:* Express the length of the plank in terms of the angle $\theta$ shown in the figure.]



▲ **Figure Ex-49**



▲ **Figure Ex-50**

**51.** Two particles, $A$ and $B$, are in motion in the $xy$-plane. Their coordinates at each instant of time $t\,(t \ge 0)$ are given by $x_A = t$, $y_A = 2t$, $x_B = 1 - t$, and $y_B = t$. Find the minimum distance between $A$ and $B$.

**52.** Follow the directions of Exercise 51, with $x_A = t$, $y_A = t^2$, $x_B = 2t$, and $y_B = 2$.

**53.** Find the coordinates of the point $P$ on the curve

$$y = \frac{1}{x^2} \quad (x > 0)$$

where the segment of the tangent line at $P$ that is cut off by the coordinate axes has its shortest length.

**54.** Find the $x$-coordinate of the point $P$ on the parabola

$$y = 1 - x^2 \quad (0 < x \le 1)$$

where the triangle that is enclosed by the tangent line at $P$ and the coordinate axes has the smallest area.

**55.** Where on the curve $y = (1 + x^2)^{-1}$ does the tangent line have the greatest slope?

**56.** Suppose that the number of bacteria in a culture at time $t$ is given by $N = 5000(25 + te^{-t/20})$.

(a) Find the largest and smallest number of bacteria in the culture during the time interval $0 \le t \le 100$.

(b) At what time during the time interval in part (a) is the number of bacteria decreasing most rapidly?

**57.** The shoreline of Circle Lake is a circle with diameter 2 mi. Nancy's training routine begins at point $E$ on the eastern shore of the lake. She jogs along the north shore to a point $P$ and then swims the straight line distance, if any, from $P$ to point $W$ diametrically opposite $E$ (Figure Ex-57). Nancy swims at a rate of 2 mi/h and jogs at 8 mi/h. How far should Nancy jog in order to complete her training routine in

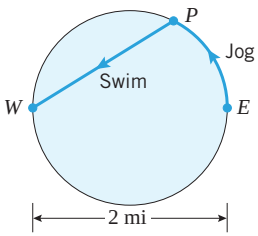
(a) the least amount of time

(b) the greatest amount of time?

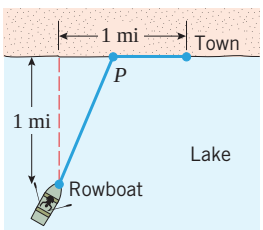
**58.** A man is floating in a rowboat 1 mile from the (straight) shoreline of a large lake. A town is located on the shoreline 1 mile from the point on the shoreline closest to the man. As suggested in Figure Ex-58, he intends to row in a straight line to some point $P$ on the shoreline and then walk the remaining distance to the town. To what point should he row in order to reach his destination in the least time if

(a) he can walk 5 mi/h and row 3 mi/h

(b) he can walk 5 mi/h and row 4 mi/h?



▲ **Figure Ex-57**



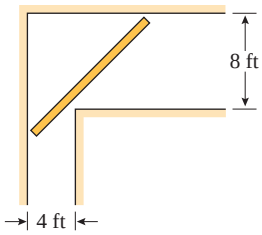
▲ **Figure Ex-58**

**59.** A pipe of negligible diameter is to be carried horizontally around a corner from a hallway 8 ft wide into a hallway 4 ft wide (Figure Ex-59 on the next page). What is the maximum length that the pipe can have?

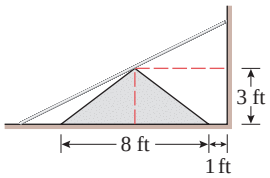
***Source:*** An interesting discussion of this problem in the case where the diameter of the pipe is not neglected is given by Norman Miller in the *American Mathematical Monthly*, Vol. 56, 1949, pp. 177–179.

**60.** A concrete barrier whose cross section is an isosceles triangle runs parallel to a wall. The height of the barrier is 3 ft, the width of the base of a cross section is 8 ft, and the barrier is positioned on level ground with its base 1 ft from the wall. A straight, stiff metal rod of negligible diameter

has one end on the ground, the other end against the wall, and touches the top of the barrier (Figure Ex-60). What is the minimum length the rod can have?



▲ Figure Ex-59



▲ Figure Ex-60

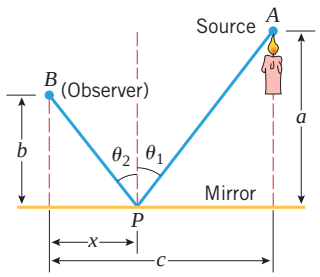
**61.** Suppose that the intensity of a point light source is directly proportional to the strength of the source and inversely proportional to the square of the distance from the source. Two point light sources with strengths of $S$ and $8S$ are separated by a distance of 90 cm. Where on the line segment between the two sources is the total intensity a minimum?

**62.** Given points $A(2, 1)$ and $B(5, 4)$, find the point $P$ in the interval $[2, 5]$ on the $x$-axis that maximizes angle $APB$.

**63.** The lower edge of a painting, 10 ft in height, is 2 ft above an observer's eye level. Assuming that the best view is obtained when the angle subtended at the observer's eye by the painting is maximum, how far from the wall should the observer stand?

**FOCUS ON CONCEPTS**

**64.** ***Fermat's principle*** (biography on p. 275) in optics states that light traveling from one point to another follows that path for which the total travel time is minimum. In a uniform medium, the paths of "minimum time" and "shortest distance" turn out to be the same, so that light, if unobstructed, travels along a straight line. Assume that we have a light source, a flat mirror, and an observer in a uniform medium. If a light ray leaves the source, bounces off the mirror, and travels on to the observer, then its path will consist of two line segments, as shown in Figure Ex-64. According to Fermat's principle, the path will be such that the total travel time $t$ is minimum or, since the medium is uniform, the path will be such that the total distance traveled from $A$ to $P$ to $B$ is as small as possible. Assuming the minimum occurs when $dt/dx = 0$, show that the light ray will strike the mirror at the point $P$ where the "angle of incidence" $\theta_1$ equals the "angle of reflection" $\theta_2$.



◀ Figure Ex-64

**65.** Fermat's principle (Exercise 64) also explains why light rays traveling between air and water undergo bending (refraction). Imagine that we have two uniform media (such as air and water) and a light ray traveling from a source $A$ in one medium to an observer $B$ in the other medium (Figure Ex-65). It is known that light travels at a constant speed in a uniform medium, but more slowly in a dense medium (such as water) than in a thin medium (such as air). Consequently, the path of shortest time from $A$ to $B$ is not necessarily a straight line, but rather some broken line path $A$ to $P$ to $B$ allowing the light to take greatest advantage of its higher speed through the thin medium. ***Snell's law of refraction*** (biography on p. 288) states that the path of the light ray will be such that

$$\frac{\sin\theta_1}{v_1} = \frac{\sin\theta_2}{v_2}$$

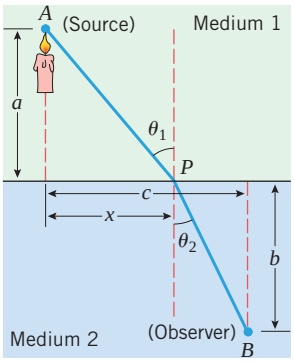
where $v_1$ is the speed of light in the first medium, $v_2$ is the speed of light in the second medium, and $\theta_1$ and $\theta_2$ are the angles shown in Figure Ex-65. Show that this follows from the assumption that the path of minimum time occurs when $dt/dx = 0$.

**66.** A farmer wants to walk at a constant rate from her barn to a straight river, fill her pail, and carry it to her house in the least time.

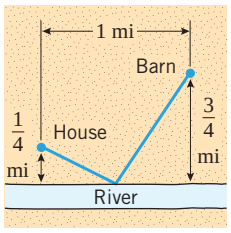
(a) Explain how this problem relates to Fermat's principle and the light-reflection problem in Exercise 64.

(b) Use the result of Exercise 64 to describe geometrically the best path for the farmer to take.

(c) Use part (b) to determine where the farmer should fill her pail if her house and barn are located as in Figure Ex-66.



▲ Figure Ex-65



▲ Figure Ex-66

**67.** If an unknown physical quantity $x$ is measured $n$ times, the measurements $x_1, x_2, \ldots, x_n$ often vary because of uncontrollable factors such as temperature, atmospheric pressure, and so forth. Thus, a scientist is often faced with the problem of using $n$ different observed measurements to obtain an estimate $\bar{x}$ of an unknown quantity $x$. One method for making such an estimate is based on the ***least squares principle***, which states that the estimate $\bar{x}$

should be chosen to minimize

$$s = (x_1 - \bar{x})^2 + (x_2 - \bar{x})^2 + \cdots + (x_n - \bar{x})^2$$

which is the sum of the squares of the deviations between the estimate $\bar{x}$ and the measured values. Show that the estimate resulting from the least squares principle is

$$\bar{x} = \frac{1}{n}(x_1 + x_2 + \cdots + x_n)$$

that is, $\bar{x}$ is the arithmetic average of the observed values.

**68.** Prove: If $f(x) \geq 0$ on an interval and if $f(x)$ has a maximum value on that interval at $x_0$, then $\sqrt{f(x)}$ also has a maximum value at $x_0$. Similarly for minimum values. [*Hint:* Use the fact that $\sqrt{x}$ is an increasing function on the interval $[0, +\infty)$.]

**69.** **Writing** Discuss the importance of finding intervals of possible values imposed by physical restrictions on variables in an applied maximum or minimum problem.

## ✔ QUICK CHECK ANSWERS 4.5

**1.** $x + \frac{1}{x}$; $(0, +\infty)$ **2.** $x(10 - x)$; $[0, 10]$ **3.** $x\left(-\frac{4}{3}x + 4\right) = -\frac{4}{3}x^2 + 4x$; $[0, 3]$
**4.** $x(20 - 2x)(32 - 2x) = 4x^3 - 104x^2 + 640x$; $[0, 10]$

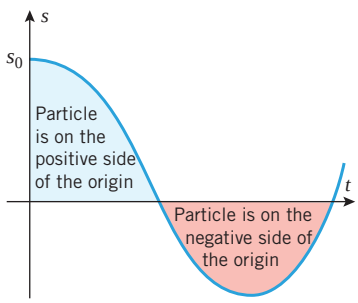
# 4.6 RECTILINEAR MOTION

*In this section we will continue the study of rectilinear motion that we began in Section 2.1. We will define the notion of "acceleration" mathematically, and we will show how the tools of calculus developed earlier in this chapter can be used to analyze rectilinear motion in more depth.*

## REVIEW OF TERMINOLOGY

Recall from Section 2.1 that a particle that can move in either direction along a coordinate line is said to be in ***rectilinear motion***. The line might be an $x$-axis, a $y$-axis, or a coordinate line inclined at some angle. In general discussions we will designate the coordinate line as the $s$-axis. We will assume that units are chosen for measuring distance and time and that we begin observing the motion of the particle at time $t = 0$. As the particle moves along the $s$-axis, its coordinate $s$ will be some function of time, say $s = s(t)$. We call $s(t)$ the ***position function*** of the particle,* and we call the graph of $s$ versus $t$ the ***position versus time curve***. If the coordinate of a particle at time $t_1$ is $s(t_1)$ and the coordinate at a later time $t_2$ is $s(t_2)$, then $s(t_2) - s(t_1)$ is called the ***displacement*** of the particle over the time interval $[t_1, t_2]$. The displacement describes the change in position of the particle.

Figure 4.6.1 shows a typical position versus time curve for a particle in rectilinear motion. We can tell from that graph that the coordinate of the particle at time $t = 0$ is $s_0$, and we can tell from the sign of $s$ when the particle is on the negative or the positive side of the origin as it moves along the coordinate line.



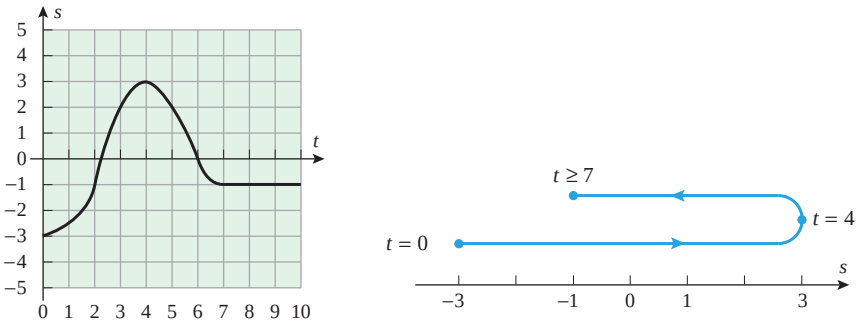
▲ **Figure 4.6.1**

* In writing $s = s(t)$, rather than the more familiar $s = f(t)$, we are using the letter $s$ both as the dependent variable and the name of the function. This is common practice in engineering and physics.

**Willebrord van Roijen Snell (1591–1626)** Dutch mathematician. Snell, who succeeded his father to the post of Professor of Mathematics at the University of Leiden in 1613, is most famous for the result of light refraction that bears his name. Although this phenomenon was studied as far back as the ancient Greek astronomer Ptolemy, until Snell's work the relationship was incorrectly thought to be $\theta_1/v_1 = \theta_2/v_2$. Snell's law was published by Descartes in 1638 without giving proper credit to Snell. Snell also discovered a method for determining distances by triangulation that founded the modern technique of mapmaking.

▶ **Example 1** Figure 4.6.2*a* shows the position versus time curve for a particle moving along an $s$-axis. In words, describe how the position of the particle changes with time.

***Solution.*** The particle is at $s = -3$ at time $t = 0$. It moves in the positive direction until time $t = 4$, since $s$ is increasing. At time $t = 4$ the particle is at position $s = 3$. At that time it turns around and travels in the negative direction until time $t = 7$, since $s$ is decreasing. At time $t = 7$ the particle is at position $s = -1$, and it remains stationary thereafter, since $s$ is constant for $t > 7$. This is illustrated schematically in Figure 4.6.2*b*. ◀



▲ **Figure 4.6.2**

## VELOCITY AND SPEED

We should more properly call $v(t)$ the ***instantaneous velocity function*** to distinguish instantaneous velocity from average velocity. However, we will follow the standard practice of referring to it as the "velocity function," leaving it understood that it describes instantaneous velocity.

Recall from Formula (5) of Section 2.1 and Formula (4) of Section 2.2 that the instantaneous velocity of a particle in rectilinear motion is the derivative of the position function. Thus, if a particle in rectilinear motion has position function $s(t)$, then we define its ***velocity function*** $v(t)$ to be

$$v(t) = s'(t) = \frac{ds}{dt} \tag{1}$$

The sign of the velocity tells which way the particle is moving—a positive value for $v(t)$ means that $s$ is increasing with time, so the particle is moving in the positive direction, and a negative value for $v(t)$ means that $s$ is decreasing with time, so the particle is moving in the negative direction. If $v(t) = 0$, then the particle has momentarily stopped.

For a particle in rectilinear motion it is important to distinguish between its ***velocity***, which describes how fast and in what direction the particle is moving, and its ***speed***, which describes only how fast the particle is moving. We make this distinction by defining speed to be the absolute value of velocity. Thus a particle with a velocity of 2 m/s has a speed of 2 m/s and is moving in the positive direction, while a particle with a velocity of $-2$ m/s also has a speed of 2 m/s but is moving in the negative direction.

Since the instantaneous speed of a particle is the absolute value of its instantaneous velocity, we define its ***speed function*** to be

$$|v(t)| = |s'(t)| = \left|\frac{ds}{dt}\right| \tag{2}$$

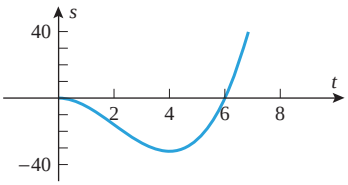
The speed function, which is always nonnegative, tells us how fast the particle is moving but not its direction of motion.

▶ **Example 2** Let $s(t) = t^3 - 6t^2$ be the position function of a particle moving along an $s$-axis, where $s$ is in meters and $t$ is in seconds. Find the velocity and speed functions, and show the graphs of position, velocity, and speed versus time.

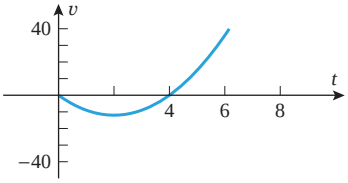
***Solution.*** From (1) and (2), the velocity and speed functions are given by

$$v(t) = \frac{ds}{dt} = 3t^2 - 12t \quad \text{and} \quad |v(t)| = |3t^2 - 12t|$$

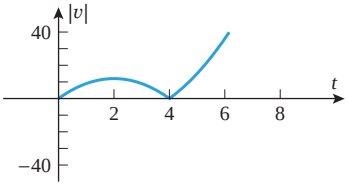
The graphs of position, velocity, and speed versus time are shown in Figure 4.6.3. Observe that velocity and speed both have units of meters per second (m/s), since $s$ is in meters (m) and time is in seconds (s). ◀



Position versus time



Velocity versus time



Speed versus time

▲ **Figure 4.6.3**

The graphs in Figure 4.6.3 provide a wealth of visual information about the motion of the particle. For example, the position versus time curve tells us that the particle is on the negative side of the origin for $0 < t < 6$, is on the positive side of the origin for $t > 6$, and is at the origin at times $t = 0$ and $t = 6$. The velocity versus time curve tells us that the particle is moving in the negative direction if $0 < t < 4$, is moving in the positive direction if $t > 4$, and is momentarily stopped at times $t = 0$ and $t = 4$ (the velocity is zero at those times). The speed versus time curve tells us that the speed of the particle is increasing for $0 < t < 2$, decreasing for $2 < t < 4$, and increasing again for $t > 4$.

## ACCELERATION

In rectilinear motion, the rate at which the instantaneous velocity of a particle changes with time is called its ***instantaneous acceleration***. Thus, if a particle in rectilinear motion has velocity function $v(t)$, then we define its ***acceleration function*** to be

$$a(t) = v'(t) = \frac{dv}{dt} \tag{3}$$

Alternatively, we can use the fact that $v(t) = s'(t)$ to express the acceleration function in terms of the position function as

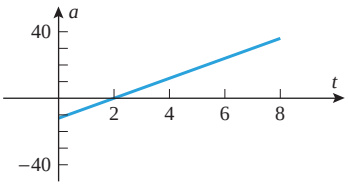
$$a(t) = s''(t) = \frac{d^2s}{dt^2} \tag{4}$$

▶ **Example 3** Let $s(t) = t^3 - 6t^2$ be the position function of a particle moving along an $s$-axis, where $s$ is in meters and $t$ is in seconds. Find the acceleration function $a(t)$, and show the graph of acceleration versus time.

***Solution.*** From Example 2, the velocity function of the particle is $v(t) = 3t^2 - 12t$, so the acceleration function is

$$a(t) = \frac{dv}{dt} = 6t - 12$$

and the acceleration versus time curve is the line shown in Figure 4.6.4. Note that in this example the acceleration has units of m/s$^2$, since $v$ is in meters per second (m/s) and time is in seconds (s). ◀



Acceleration versus time

▲ **Figure 4.6.4**

## SPEEDING UP AND SLOWING DOWN

We will say that a particle in rectilinear motion is ***speeding up*** when its speed is increasing and is ***slowing down*** when its speed is decreasing. In everyday language an object that is speeding up is said to be "accelerating" and an object that is slowing down is said to be "decelerating"; thus, one might expect that a particle in rectilinear motion will be speeding up when its acceleration is positive and slowing down when it is negative. Although this is true for a particle moving in the positive direction, it is *not* true for a particle moving in the

negative direction—a particle with negative velocity is speeding up when its acceleration is negative and slowing down when its acceleration is positive. This is because a positive acceleration implies an increasing velocity, and increasing a negative velocity decreases its absolute value; similarly, a negative acceleration implies a decreasing velocity, and decreasing a negative velocity increases its absolute value.

The preceding informal discussion can be summarized as follows (Exercise 41):

If $a(t) = 0$ over a certain time interval, what does this tell you about the motion of the particle during that time?

**INTERPRETING THE SIGN OF ACCELERATION** *A particle in rectilinear motion is speeding up when its velocity and acceleration have the same sign and slowing down when they have opposite signs.*

▶ **Example 4** In Examples 2 and 3 we found the velocity versus time curve and the acceleration versus time curve for a particle with position function $s(t) = t^3 - 6t^2$. Use those curves to determine when the particle is speeding up and slowing down, and confirm that your results are consistent with the speed versus time curve obtained in Example 2.

***Solution.*** Over the time interval $0 < t < 2$ the velocity and acceleration are negative, so the particle is speeding up. This is consistent with the speed versus time curve, since the speed is increasing over this time interval. Over the time interval $2 < t < 4$ the velocity is negative and the acceleration is positive, so the particle is slowing down. This is also consistent with the speed versus time curve, since the speed is decreasing over this time interval. Finally, on the time interval $t > 4$ the velocity and acceleration are positive, so the particle is speeding up, which again is consistent with the speed versus time curve. ◀

## ANALYZING THE POSITION VERSUS TIME CURVE

The position versus time curve contains all of the significant information about the position and velocity of a particle in rectilinear motion:

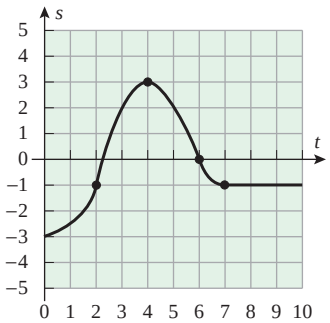
- If $s(t) > 0$, the particle is on the positive side of the $s$-axis.
- If $s(t) < 0$, the particle is on the negative side of the $s$-axis.
- The slope of the curve at any time is equal to the instantaneous velocity at that time.
- Where the curve has positive slope, the velocity is positive and the particle is moving in the positive direction.
- Where the curve has negative slope, the velocity is negative and the particle is moving in the negative direction.
- Where the slope of the curve is zero, the velocity is zero, and the particle is momentarily stopped.

Information about the acceleration of a particle in rectilinear motion can also be deduced from the position versus time curve by examining its concavity. For example, we know that the position versus time curve will be concave up on intervals where $s''(t) > 0$ and will be concave down on intervals where $s''(t) < 0$. But we know from (4) that $s''(t)$ is the acceleration, so that on intervals where the position versus time curve is concave up the particle has a positive acceleration, and on intervals where it is concave down the particle has a negative acceleration.

Table 4.6.1 summarizes our observations about the position versus time curve.

**Table 4.6.1**
ANALYSIS OF PARTICLE MOTION

| POSITION VERSUS TIME CURVE | CHARACTERISTICS OF THE CURVE AT $t = t_0$ | BEHAVIOR OF THE PARTICLE AT TIME $t = t_0$ |
|---|---|---|
|  | • $s(t_0) > 0$<br>• Curve has positive slope.<br>• Curve is concave down. | • Particle is on the positive side of the origin.<br>• Particle is moving in the positive direction.<br>• Velocity is decreasing.<br>• Particle is slowing down. |
|  | • $s(t_0) > 0$<br>• Curve has negative slope.<br>• Curve is concave down. | • Particle is on the positive side of the origin.<br>• Particle is moving in the negative direction.<br>• Velocity is decreasing.<br>• Particle is speeding up. |
|  | • $s(t_0) < 0$<br>• Curve has negative slope.<br>• Curve is concave up. | • Particle is on the negative side of the origin.<br>• Particle is moving in the negative direction.<br>• Velocity is increasing.<br>• Particle is slowing down. |
|  | • $s(t_0) > 0$<br>• Curve has zero slope.<br>• Curve is concave down. | • Particle is on the positive side of the origin.<br>• Particle is momentarily stopped.<br>• Velocity is decreasing. |



▲ Figure 4.6.5

► **Example 5** Use the position versus time curve in Figure 4.6.5 to determine when the particle in Example 1 is speeding up and slowing down.

***Solution.*** From $t = 0$ to $t = 2$, the acceleration and velocity are positive, so the particle is speeding up. From $t = 2$ to $t = 4$, the acceleration is negative and the velocity is positive, so the particle is slowing down. At $t = 4$, the velocity is zero, so the particle has momentarily stopped. From $t = 4$ to $t = 6$, the acceleration is negative and the velocity is negative, so the particle is speeding up. From $t = 6$ to $t = 7$, the acceleration is positive and the velocity is negative, so the particle is slowing down. Thereafter, the velocity is zero, so the particle has stopped. ◄

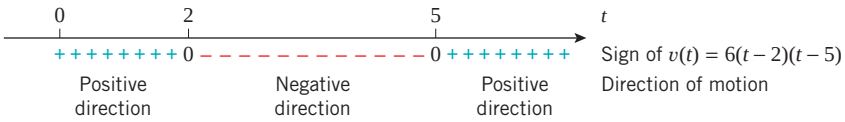
► **Example 6** Suppose that the position function of a particle moving on a coordinate line is given by $s(t) = 2t^3 - 21t^2 + 60t + 3$. Analyze the motion of the particle for $t \geq 0$.

***Solution.*** The velocity and acceleration functions are

$$v(t) = s'(t) = 6t^2 - 42t + 60 = 6(t - 2)(t - 5)$$
$$a(t) = v'(t) = 12t - 42 = 12\left(t - \tfrac{7}{2}\right)$$

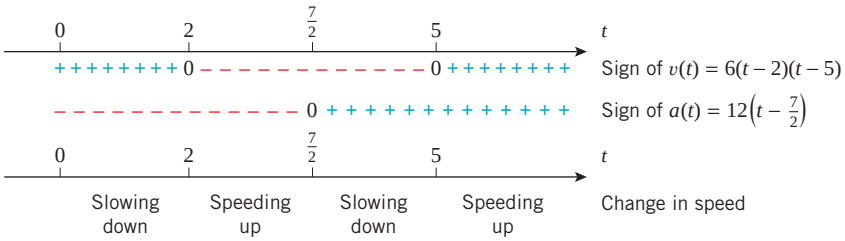
- *Direction of motion:* The sign analysis of the velocity function in Figure 4.6.6 shows that the particle is moving in the positive direction over the time interval $0 \leq t < 2$,

stops momentarily at time $t = 2$, moves in the negative direction over the time interval $2 < t < 5$, stops momentarily at time $t = 5$, and then moves in the positive direction thereafter.



▲ **Figure 4.6.6**

- *Change in speed:* A comparison of the signs of the velocity and acceleration functions is shown in Figure 4.6.7. Since the particle is speeding up when the signs are the same and is slowing down when they are opposite, we see that the particle is slowing down over the time interval $0 \le t < 2$ and stops momentarily at time $t = 2$. It is then speeding up over the time interval $2 < t < \frac{7}{2}$. At time $t = \frac{7}{2}$ the instantaneous acceleration is zero, so the particle is neither speeding up nor slowing down. It is then slowing down over the time interval $\frac{7}{2} < t < 5$ and stops momentarily at time $t = 5$. Thereafter, it is speeding up.



▲ **Figure 4.6.7**

*Conclusions:* The diagram in Figure 4.6.8 summarizes the above information schematically. The curved line is descriptive only; the actual path is back and forth on the coordinate line. The coordinates of the particle at times $t = 0$, $t = 2$, $t = \frac{7}{2}$, and $t = 5$ were computed from $s(t)$. Segments in red indicate that the particle is speeding up and segments in blue indicate that it is slowing down. ◀

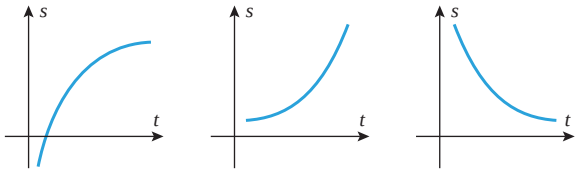
## ✔ QUICK CHECK EXERCISES 4.6 (See page 296 for answers.)

1. For a particle in rectilinear motion, the velocity and position functions $v(t)$ and $s(t)$ are related by the equation _____, and the acceleration and velocity functions $a(t)$ and $v(t)$ are related by the equation _____.
2. Suppose that a particle moving along the $s$-axis has position function $s(t) = 7t - 2t^2$. At time $t = 3$, the particle's position is _____, its velocity is _____, its speed is _____, and its acceleration is _____.
3. A particle in rectilinear motion is speeding up if the signs of its velocity and acceleration are _____, and it is slowing down if these signs are _____.
4. Suppose that a particle moving along the $s$-axis has position function $s(t) = t^4 - 24t^2$ over the time interval $t \ge 0$. The particle slows down over the time interval(s) _____.

## EXERCISE SET 4.6 Graphing Utility

### FOCUS ON CONCEPTS

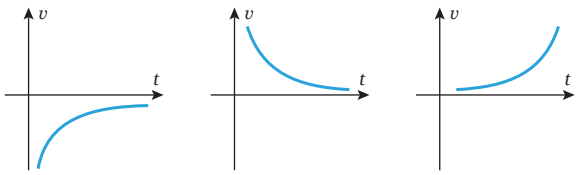
**1.** The graphs of three position functions are shown in the accompanying figure. In each case determine the signs of the velocity and acceleration, and then determine whether the particle is speeding up or slowing down.



(a) (b) (c)

▲ **Figure Ex-1**

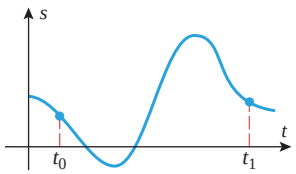
**2.** The graphs of three velocity functions are shown in the accompanying figure. In each case determine the sign of the acceleration, and then determine whether the particle is speeding up or slowing down.



(a) (b) (c)

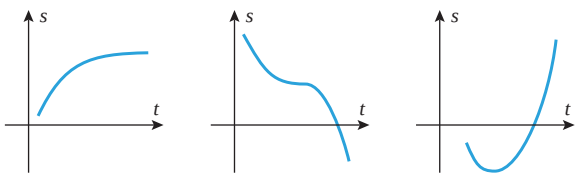
▲ **Figure Ex-2**

**3.** The graph of the position function of a particle moving on a horizontal line is shown in the accompanying figure.
(a) Is the particle moving left or right at time $t_0$?
(b) Is the acceleration positive or negative at time $t_0$?
(c) Is the particle speeding up or slowing down at time $t_0$?
(d) Is the particle speeding up or slowing down at time $t_1$?

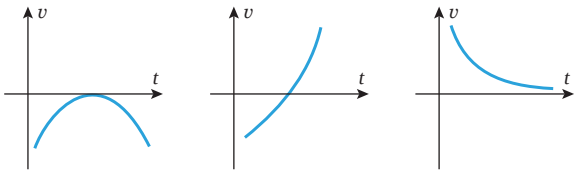


◀ **Figure Ex-3**

**4.** For the graphs in the accompanying figure, match the position functions (a)–(c) with their corresponding velocity functions (I)–(III).



(a) (b) (c)

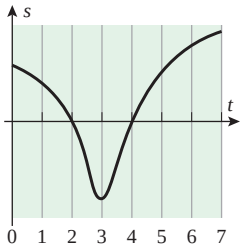


(I) (II) (III)

▲ **Figure Ex-4**

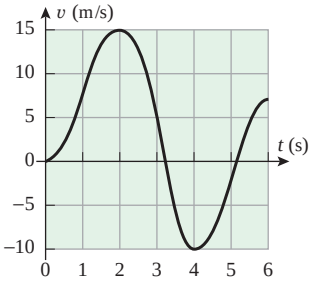
**5.** Sketch a reasonable graph of $s$ versus $t$ for a mouse that is trapped in a narrow corridor (an $s$-axis with the positive direction to the right) and scurries back and forth as follows. It runs right with a constant speed of 1.2 m/s for a while, then gradually slows down to 0.6 m/s, then quickly speeds up to 2.0 m/s, then gradually slows to a stop but immediately reverses direction and quickly speeds up to 1.2 m/s.

**6.** The accompanying figure shows the position versus time curve for an ant that moves along a narrow vertical pipe, where $t$ is measured in seconds and the $s$-axis is along the pipe with the positive direction up.
(a) When, if ever, is the ant above the origin?
(b) When, if ever, does the ant have velocity zero?
(c) When, if ever, is the ant moving down the pipe?



◀ **Figure Ex-6**

**7.** The accompanying figure shows the graph of velocity versus time for a particle moving along a coordinate line. Make a rough sketch of the graphs of speed versus time and acceleration versus time.

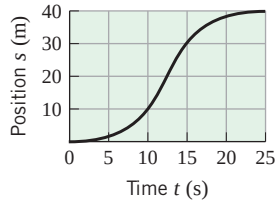


◀ **Figure Ex-7**

**8.** The accompanying figure (on the next page) shows the position versus time graph for an elevator that ascends 40 m from one stop to the next.
(a) Estimate the velocity when the elevator is halfway up to the top.

(cont.)

(b) Sketch rough graphs of the velocity versus time curve and the acceleration versus time curve.



◀ **Figure Ex-8**

**9–12 True–False** Determine whether the statement is true or false. Explain your answer. ■

**9.** A particle is speeding up when its position versus time graph is increasing.

**10.** Velocity is the derivative of position with respect to time.

**11.** Acceleration is the absolute value of velocity.

**12.** If the position versus time curve is increasing and concave down, then the particle is slowing down.

**13.** The accompanying figure shows the velocity versus time graph for a test run on a Chevrolet Volt. Using this graph, estimate

(a) the acceleration at 60 mi/h (in ft/s$^2$)

(b) the time at which the maximum acceleration occurs.

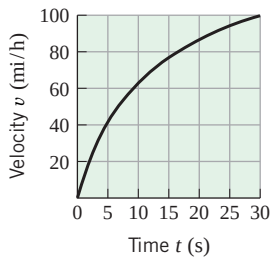
***Source:*** Data from *Car and Driver Magazine*, December 2010.

**14.** The accompanying figure shows the velocity versus time graph for a test run on a Dodge Challenger. Using this graph, estimate

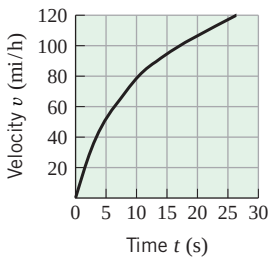
(a) the acceleration at 60 mi/h (in ft/s$^2$)

(b) the time at which the maximum acceleration occurs.

***Source:*** Data from *Car and Driver Magazine*, March 2011.



▲ **Figure Ex-13**



▲ **Figure Ex-14**

**15–16** The function $s(t)$ describes the position of a particle moving along a coordinate line, where $s$ is in meters and $t$ is in seconds.

(a) Make a table showing the position, velocity, and acceleration to two decimal places at times $t = 1, 2, 3, 4, 5$.

(b) At each of the times in part (a), determine whether the particle is stopped; if it is not, state its direction of motion.

(c) At each of the times in part (a), determine whether the particle is speeding up, slowing down, or neither. ■

**15.** $s(t) = \sin\dfrac{\pi t}{4}$

**16.** $s(t) = t^4 e^{-t}, \quad t \geq 0$

**17–22** The function $s(t)$ describes the position of a particle moving along a coordinate line, where $s$ is in feet and $t$ is in seconds.

(a) Find the velocity and acceleration functions.

(b) Find the position, velocity, speed, and acceleration at time $t = 1$.

(c) At what times is the particle stopped?

(d) When is the particle speeding up? Slowing down?

(e) Find the total distance traveled by the particle from time $t = 0$ to time $t = 5$. ■

**17.** $s(t) = t^3 - 3t^2, \quad t \geq 0$

**18.** $s(t) = t^4 - 4t^2 + 4, \quad t \geq 0$

**19.** $s(t) = 9 - 9\cos(\pi t/3), \quad 0 \leq t \leq 5$

**20.** $s(t) = \dfrac{t}{t^2 + 4}, \quad t \geq 0$

**21.** $s(t) = (t^2 + 8)e^{-t/3}, \quad t \geq 0$

**22.** $s(t) = \frac{1}{4}t^2 - \ln(t + 1), \quad t \geq 0$

**23.** Let $s(t) = t/(t^2 + 5)$ be the position function of a particle moving along a coordinate line, where $s$ is in meters and $t$ is in seconds. Use a graphing utility to generate the graphs of $s(t)$, $v(t)$, and $a(t)$ for $t \geq 0$, and use those graphs where needed.

(a) Use the appropriate graph to make a rough estimate of the time at which the particle first reverses the direction of its motion; and then find the time exactly.

(b) Find the exact position of the particle when it first reverses the direction of its motion.

(c) Use the appropriate graphs to make a rough estimate of the time intervals on which the particle is speeding up and on which it is slowing down; and then find those time intervals exactly.

**24.** Let $s(t) = t/e^t$ be the position function of a particle moving along a coordinate line, where $s$ is in meters and $t$ is in seconds. Use a graphing utility to generate the graphs of $s(t)$, $v(t)$, and $a(t)$ for $t \geq 0$, and use those graphs where needed.

(a) Use the appropriate graph to make a rough estimate of the time at which the particle first reverses the direction of its motion; and then find the time exactly.

(b) Find the exact position of the particle when it first reverses the direction of its motion.

(c) Use the appropriate graphs to make a rough estimate of the time intervals on which the particle is speeding up and on which it is slowing down; and then find those time intervals exactly.

**25–32** A position function of a particle moving along a coordinate line is given. Use the method of Example 6 to analyze the motion of the particle for $t \geq 0$, and give a schematic picture of the motion (as in Figure 4.6.8). ■

**25.** $s = -4t + 3$

**26.** $s = 5t^2 - 20t$

**27.** $s = t^3 - 9t^2 + 24t$

**28.** $s = t^3 - 6t^2 + 9t + 1$

**29.** $s = 16te^{-(t^2/8)}$ **30.** $s = t + \dfrac{25}{t+2}$

**31.** $s = \begin{cases} \cos t, & 0 \le t < 2\pi \\ 1, & t \ge 2\pi \end{cases}$

**32.** $s = \begin{cases} 2t(t-2)^2, & 0 \le t < 3 \\ 13 - 7(t-4)^2, & t \ge 3 \end{cases}$

**33.** Let $s(t) = 5t^2 - 22t$ be the position function of a particle moving along a coordinate line, where $s$ is in feet and $t$ is in seconds.
(a) Find the maximum speed of the particle during the time interval $1 \le t \le 3$.
(b) When, during the time interval $1 \le t \le 3$, is the particle farthest from the origin? What is its position at that instant?

**34.** Let $s = 100/(t^2 + 12)$ be the position function of a particle moving along a coordinate line, where $s$ is in feet and $t$ is in seconds. Find the maximum speed of the particle for $t \ge 0$, and find the direction of motion of the particle when it has its maximum speed.

**35–36** A position function of a particle moving along a coordinate line is provided. (a) Evaluate $s$ and $v$ when $a = 0$. (b) Evaluate $s$ and $a$ when $v = 0$. ■

**35.** $s = \ln(3t^2 - 12t + 13)$ **36.** $s = t^3 - 6t^2 + 1$

**37.** Let $s = \sqrt{2t^2 + 1}$ be the position function of a particle moving along a coordinate line.
(a) Use a graphing utility to generate the graph of $v$ versus $t$, and make a conjecture about the velocity of the particle as $t \to +\infty$.
(b) Check your conjecture by finding $\lim_{t \to +\infty} v$.

**38.** (a) Use the chain rule to show that for a particle in rectilinear motion $a = v(dv/ds)$.
(b) Let $s = \sqrt{3t + 7}$, $t \ge 0$. Find a formula for $v$ in terms of $s$ and use the equation in part (a) to find the acceleration when $s = 5$.

**39.** Suppose that the position functions of two particles, $P_1$ and $P_2$, in motion along the same line are

$$s_1 = \tfrac{1}{2}t^2 - t + 3 \quad \text{and} \quad s_2 = -\tfrac{1}{4}t^2 + t + 1$$

respectively, for $t \ge 0$.
(a) Prove that $P_1$ and $P_2$ do not collide.
(b) How close do $P_1$ and $P_2$ get to each other?
(c) During what intervals of time are they moving in opposite directions?

**40.** Let $s_A = 15t^2 + 10t + 20$ and $s_B = 5t^2 + 40t$, $t \ge 0$, be the position functions of cars $A$ and $B$ that are moving along parallel straight lanes of a highway.
(a) How far is car $A$ ahead of car $B$ when $t = 0$?
(b) At what instants of time are the cars next to each other?
(c) At what instant of time do they have the same velocity? Which car is ahead at this instant?

**41.** Prove that a particle is speeding up if the velocity and acceleration have the same sign, and slowing down if they have opposite signs. [*Hint:* Let $r(t) = |v(t)|$ and find $r'(t)$ using the chain rule.]

**42.** **Writing** A speedometer on a bicycle calculates the bicycle's speed by measuring the time per rotation for one of the bicycle's wheels. Explain how this measurement can be used to calculate an average velocity for the bicycle, and discuss how well it approximates the instantaneous velocity for the bicycle.

**43.** **Writing** A toy rocket is launched into the air and falls to the ground after its fuel runs out. Describe the rocket's acceleration and when the rocket is speeding up or slowing down during its flight. Accompany your description with a sketch of a graph of the rocket's acceleration versus time.

### ✔ QUICK CHECK ANSWERS 4.6

## 4.7 NEWTON'S METHOD

*In Section 1.5 we showed how to approximate the roots of an equation $f(x) = 0$ using the Intermediate-Value Theorem. In this section we will study a technique, called "Newton's Method," that is usually more efficient than that method. Newton's Method is the technique used by many commercial and scientific computer programs for finding roots.*

### NEWTON'S METHOD

In beginning algebra one learns that the solution of a first-degree equation $ax + b = 0$ is given by the formula $x = -b/a$, and the solutions of a second-degree equation

$$ax^2 + bx + c = 0$$

are given by the quadratic formula. Formulas also exist for the solutions of all third- and fourth-degree equations, although they are too complicated to be of practical use. In 1826 it was shown by the Norwegian mathematician Niels Henrik Abel that it is impossible to construct a similar formula for the solutions of a *general* fifth-degree equation or higher. Thus, for a *specific* fifth-degree polynomial equation such as

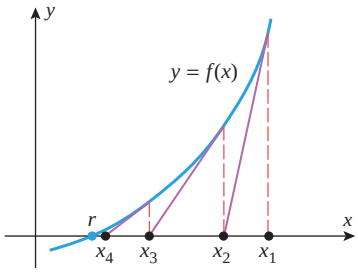
$$x^5 - 9x^4 + 2x^3 - 5x^2 + 17x - 8 = 0$$

it may be difficult or impossible to find exact values for all of the solutions. Similar difficulties occur for nonpolynomial equations such as

$$x - \cos x = 0$$

For such equations the solutions are generally approximated in some way, often by the method we will now discuss.

Suppose that we are trying to find a root $r$ of the equation $f(x) = 0$, and suppose that by some method we are able to obtain an initial rough estimate, $x_1$, of $r$, say by generating the graph of $y = f(x)$ with a graphing utility and examining the $x$-intercept. If $f(x_1) = 0$, then $r = x_1$. If $f(x_1) \neq 0$, then we consider an easier problem, that of finding a root to a linear equation. The best linear approximation to $y = f(x)$ near $x = x_1$ is given by the tangent line to the graph of $f$ at $x_1$, so it might be reasonable to expect that the $x$-intercept to this tangent line provides an improved approximation to $r$. Call this intercept $x_2$ (Figure 4.7.1). We can now treat $x_2$ in the same way we did $x_1$. If $f(x_2) = 0$, then $r = x_2$. If $f(x_2) \neq 0$, then construct the tangent line to the graph of $f$ at $x_2$, and take $x_3$ to be the $x$-intercept of this tangent line. Continuing in this way we can generate a succession of values $x_1, x_2, x_3, x_4, \ldots$ that will usually approach $r$. This procedure for approximating $r$ is called ***Newton's Method***.



▲ **Figure 4.7.1**

To implement Newton's Method analytically, we must derive a formula that will tell us how to calculate each improved approximation from the preceding approximation. For this purpose, we note that the point-slope form of the tangent line to $y = f(x)$ at the initial

**Niels Henrik Abel (1802–1829)** Norwegian mathematician. Abel was the son of a poor Lutheran minister and a remarkably beautiful mother from whom he inherited strikingly good looks. In his brief life of 26 years Abel lived in virtual poverty and suffered a succession of adversities, yet he managed to prove major results that altered the mathematical landscape forever. At the age of thirteen he was sent away from home to a school whose better days had long passed. By a stroke of luck the school had just hired a teacher named Bernt Michael Holmboe, who quickly discovered that Abel had extraordinary mathematical ability. Together, they studied the calculus texts of Euler and works of Newton and the later French mathematicians. By the time he graduated, Abel was familar with most of the great mathematical literature. In 1820 his father died, leaving the family in dire financial straits. Abel was able to enter the University of Christiania in Oslo only because he was granted a free room and several professors supported him directly from their salaries. The University had no advanced courses in mathematics, so Abel took a preliminary degree in 1822 and then continued to study mathematics on his own. In 1824 he published at his own expense the proof that it is impossible to solve the general fifth-degree polynomial equation algebraically. With the hope that this landmark paper would lead to his recognition and acceptance by the European mathematical community, Abel sent the paper to the great German mathematician Gauss, who casually declared it to be a "monstrosity" and tossed it aside. However, in 1826 Abel's paper on the fifth-degree equation and other work was published in the first issue of a new journal, founded by his friend, Leopold Crelle. In the summer of 1826 he completed a landmark work on transcendental functions, which he submitted to the French Academy of Sciences. He hoped to establish himself as a major mathematician, for many young mathematicians had gained quick distinction by having their work accepted by the Academy. However, Abel waited in vain because the paper was either ignored or misplaced by one of the referees, and it did not surface again until two years after his death. That paper was later described by one major mathematician as "…the most important mathematical discovery that has been made in our century…." After submitting his paper, Abel returned to Norway, ill with tuberculosis and in heavy debt. While eking out a meager living as a tutor, he continued to produce great work and his fame spread. Soon great efforts were being made to secure a suitable mathematical position for him. Fearing that his great work had been lost by the Academy, he mailed a proof of the main results to Crelle in January of 1829. In April he suffered a violent hemorrhage and died. Two days later Crelle wrote to inform him that an appointment had been secured for him in Berlin and his days of poverty were over! Abel's great paper was finally published by the Academy twelve years after his death.

[*Image: http://en.wikipedia.org/wiki/File:Niels_Henrik_Abel2.jpg*]

approximation $x_1$ is

$$y - f(x_1) = f'(x_1)(x - x_1) \tag{1}$$

If $f'(x_1) \neq 0$, then this line is not parallel to the $x$-axis and consequently it crosses the $x$-axis at some point $(x_2, 0)$. Substituting the coordinates of this point in (1) yields

$$-f(x_1) = f'(x_1)(x_2 - x_1)$$

Solving for $x_2$ we obtain

$$x_2 = x_1 - \frac{f(x_1)}{f'(x_1)} \tag{2}$$

The next approximation can be obtained more easily. If we view $x_2$ as the starting approximation and $x_3$ the new approximation, we can simply apply (2) with $x_2$ in place of $x_1$ and $x_3$ in place of $x_2$. This yields

$$x_3 = x_2 - \frac{f(x_2)}{f'(x_2)} \tag{3}$$

provided $f'(x_2) \neq 0$. In general, if $x_n$ is the $n$th approximation, then it is evident from the pattern in (2) and (3) that the improved approximation $x_{n+1}$ is given by

***Newton's Method***

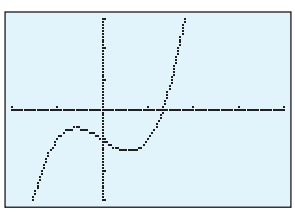
$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}, \quad n = 1, 2, 3, \ldots \tag{4}$$

▶ **Example 1** Use Newton's Method to approximate the real solutions of

$$x^3 - x - 1 = 0$$

***Solution.*** Let $f(x) = x^3 - x - 1$, so $f'(x) = 3x^2 - 1$ and (4) becomes

$$x_{n+1} = x_n - \frac{x_n^3 - x_n - 1}{3x_n^2 - 1} \tag{5}$$



$[-2, 4] \times [-3, 3]$
$x\text{Scl} = 1, y\text{Scl} = 1$

$y = x^3 - x - 1$

▲ **Figure 4.7.2**

From the graph of $f$ in Figure 4.7.2, we see that the given equation has only one real solution. This solution lies between 1 and 2 because $f(1) = -1 < 0$ and $f(2) = 5 > 0$. We will use $x_1 = 1.5$ as our first approximation ($x_1 = 1$ or $x_1 = 2$ would also be reasonable choices).

Letting $n = 1$ in (5) and substituting $x_1 = 1.5$ yields

$$x_2 = 1.5 - \frac{(1.5)^3 - 1.5 - 1}{3(1.5)^2 - 1} \approx 1.34782609 \tag{6}$$

(We used a calculator that displays nine digits.) Next, we let $n = 2$ in (5) and substitute $x_2$ to obtain

$$x_3 = x_2 - \frac{x_2^3 - x_2 - 1}{3x_2^2 - 1} \approx 1.32520040 \tag{7}$$

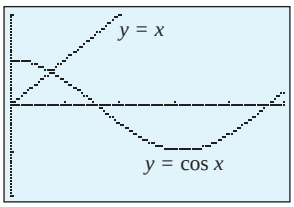
If we continue this process until two identical approximations are generated in succession, we obtain

$$\begin{aligned} x_1 &= 1.5 \\ x_2 &\approx 1.34782609 \\ x_3 &\approx 1.32520040 \\ x_4 &\approx 1.32471817 \\ x_5 &\approx 1.32471796 \\ x_6 &\approx 1.32471796 \end{aligned}$$

**TECHNOLOGY MASTERY**

Many calculators and computer programs calculate internally with more digits than they display. Where possible, you should use stored calculated values rather than values displayed from earlier calculations. Thus, in Example 1 the value of $x_2$ used in (7) should be the stored value, not the value in (6).

At this stage there is no need to continue further because we have reached the display accuracy limit of our calculator, and all subsequent approximations that the calculator generates will likely be the same. Thus, the solution is approximately $x \approx 1.32471796$. ◀



[0, 5] × [−2, 2]
xScl = 1, yScl = 1

▲ **Figure 4.7.3**

▶ **Example 2** It is evident from Figure 4.7.3 that if $x$ is in radians, then the equation

$$\cos x = x$$

has a solution between 0 and 1. Use Newton's Method to approximate it.

***Solution.*** Rewrite the equation as

$$x - \cos x = 0$$

and apply (4) with $f(x) = x - \cos x$. Since $f'(x) = 1 + \sin x$, (4) becomes

$$x_{n+1} = x_n - \frac{x_n - \cos x_n}{1 + \sin x_n} \tag{8}$$

From Figure 4.7.3, the solution seems closer to $x = 1$ than $x = 0$, so we will use $x_1 = 1$ (radian) as our initial approximation. Letting $n = 1$ in (8) and substituting $x_1 = 1$ yields

$$x_2 = 1 - \frac{1 - \cos 1}{1 + \sin 1} \approx 0.750363868$$

Next, letting $n = 2$ in (8) and substituting this value of $x_2$ yields

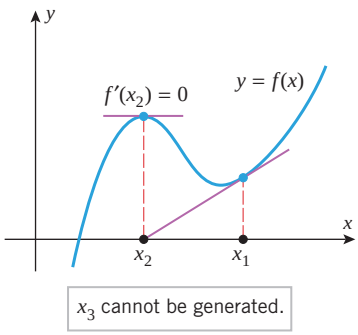
$$x_3 = x_2 - \frac{x_2 - \cos x_2}{1 + \sin x_2} \approx 0.739112891$$

If we continue this process until two identical approximations are generated in succession, we obtain

$$\begin{aligned} x_1 &= 1 \\ x_2 &\approx 0.750363868 \\ x_3 &\approx 0.739112891 \\ x_4 &\approx 0.739085133 \\ x_5 &\approx 0.739085133 \end{aligned}$$

Thus, to the accuracy limit of our calculator, the solution of the equation $\cos x = x$ is $x \approx 0.739085133$. ◀

## SOME DIFFICULTIES WITH NEWTON'S METHOD



▲ **Figure 4.7.4**

When Newton's Method works, the approximations usually converge toward the solution with dramatic speed. However, there are situations in which the method fails. For example, if $f'(x_n) = 0$ for some $n$, then (4) involves a division by zero, making it impossible to generate $x_{n+1}$. However, this is to be expected because the tangent line to $y = f(x)$ is parallel to the $x$-axis where $f'(x_n) = 0$, and hence this tangent line does not cross the $x$-axis to generate the next approximation (Figure 4.7.4).

Newton's Method can fail for other reasons as well; sometimes it may overlook the root you are trying to find and converge to a different root, and sometimes it may fail to converge altogether. For example, consider the equation

$$x^{1/3} = 0$$

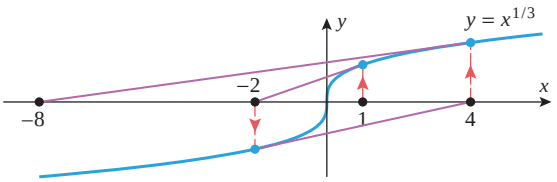
which has $x = 0$ as its only solution, and try to approximate this solution by Newton's Method with a starting value of $x_0 = 1$. Letting $f(x) = x^{1/3}$, Formula (4) becomes

$$x_{n+1} = x_n - \frac{(x_n)^{1/3}}{\frac{1}{3}(x_n)^{-2/3}} = x_n - 3x_n = -2x_n$$

Beginning with $x_1 = 1$, the successive values generated by this formula are

$$x_1 = 1, \quad x_2 = -2, \quad x_3 = 4, \quad x_4 = -8, \ldots$$

which obviously do not converge to $x = 0$. Figure 4.7.5 illustrates what is happening geometrically in this situation.

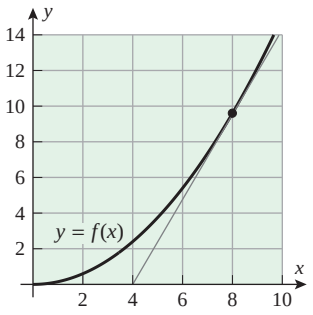


▶ **Figure 4.7.5**

To learn more about the conditions under which Newton's Method converges and for a discussion of error questions, you should consult a book on numerical analysis. For a more in-depth discussion of Newton's Method and its relationship to contemporary studies of chaos and fractals, you may want to read the article, "Newton's Method and Fractal Patterns," by Philip Straffin, which appears in *Applications of Calculus*, MAA Notes, Vol. 3, No. 29, 1993, published by the Mathematical Association of America.

## ✔ QUICK CHECK EXERCISES 4.7 (See page 302 for answers.)

1. Use the accompanying graph to estimate $x_2$ and $x_3$ if Newton's Method is applied to the equation $y = f(x)$ with $x_1 = 8$.
2. Suppose that $f(1) = 2$ and $f'(1) = 4$. If Newton's Method is applied to $y = f(x)$ with $x_1 = 1$, then $x_2 =$ _____.
3. Suppose we are given that $f(0) = 3$ and that $x_2 = 3$ when Newton's Method is applied to $y = f(x)$ with $x_1 = 0$. Then $f'(0) =$ _____.
4. If Newton's Method is applied to $y = e^x - 1$ with $x_1 = \ln 2$, then $x_2 =$ _____.



◀ **Figure Ex-1**

## EXERCISE SET 4.7 Graphing Utility

In this exercise set, express your answers with as many decimal digits as your calculating utility can display, but use the procedure in the Technology Mastery on p. 298. ■

1. Approximate $\sqrt{2}$ by applying Newton's Method to the equation $x^2 - 2 = 0$.
2. Approximate $\sqrt{5}$ by applying Newton's Method to the equation $x^2 - 5 = 0$.
3. Approximate $\sqrt[3]{6}$ by applying Newton's Method to the equation $x^3 - 6 = 0$.
4. To what equation would you apply Newton's Method to approximate the $n$th root of $a$?

**5–8** The given equation has one real solution. Approximate it by Newton's Method. ■

5. $x^3 - 2x - 2 = 0$
6. $x^3 + x - 1 = 0$
7. $x^5 + x^4 - 5 = 0$
8. $x^5 - 3x + 3 = 0$

**9–14** Use a graphing utility to determine how many solutions the equation has, and then use Newton's Method to approximate the solution that satisfies the stated condition. ■

9. $x^4 + x^2 - 4 = 0;\ x < 0$
10. $x^5 - 5x^3 - 2 = 0;\ x > 0$
11. $2\cos x = x;\ x > 0$
12. $\sin x = x^2;\ x > 0$

**13.** $x - \tan x = 0;\ \pi/2 < x < 3\pi/2$

**14.** $1 + e^x \sin x = 0;\ \pi/2 < x < 3\pi/2$

**15–20** Use a graphing utility to determine the number of times the curves intersect; and then apply Newton's Method, where needed, to approximate the $x$-coordinates of all intersections.

**15.** $y = x^3$ and $y = 1 - x$

**16.** $y = \sin x$ and $y = x^3 - 2x^2 + 1$

**17.** $y = x^2$ and $y = \sqrt{2x + 1}$

**18.** $y = \frac{1}{8}x^3 - 1$ and $y = \cos x - 2$

**19.** $y = 1$ and $y = e^x \sin x;\ 0 < x < \pi$

**20.** $y = e^{-x}$ and $y = \ln x$

**21–24 True–False** Determine whether the statement is true or false. Explain your answer.

**21.** Newton's Method uses the tangent line to $y = f(x)$ at $x = x_n$ to compute $x_{n+1}$.

**22.** Newton's Method is a process to find exact solutions to $f(x) = 0$.

**23.** If $f(x) = 0$ has a root, then Newton's Method starting at $x = x_1$ will approximate the root nearest $x_1$.

**24.** Newton's Method can be used to appoximate a point of intersection of two curves.

**25.** The ***mechanic's rule*** for approximating square roots states that $\sqrt{a} \approx x_{n+1}$, where

$$x_{n+1} = \frac{1}{2}\left(x_n + \frac{a}{x_n}\right), \quad n = 1, 2, 3, \ldots$$

and $x_1$ is any positive approximation to $\sqrt{a}$.

(a) Apply Newton's Method to

$$f(x) = x^2 - a$$

to derive the mechanic's rule.

(b) Use the mechanic's rule to approximate $\sqrt{10}$.

**26.** Many calculators compute reciprocals using the approximation $1/a \approx x_{n+1}$, where

$$x_{n+1} = x_n(2 - ax_n), \quad n = 1, 2, 3, \ldots$$

and $x_1$ is an initial approximation to $1/a$. This formula makes it possible to perform divisions using multiplications and subtractions, which is a faster procedure than dividing directly.

(a) Apply Newton's Method to

$$f(x) = \frac{1}{x} - a$$

to derive this approximation.

(b) Use the formula to approximate $\frac{1}{17}$.

**27.** Use Newton's Method to approximate the absolute minimum of $f(x) = \frac{1}{4}x^4 + x^2 - 5x$.

**28.** Use Newton's Method to approximate the absolute maximum of $f(x) = x \sin x$ on the interval $[0, \pi]$.

**29.** For the function

$$f(x) = \frac{e^{-x}}{1 + x^2}$$

use Newton's Method to approximate the $x$-coordinates of the inflection points to two decimal places.

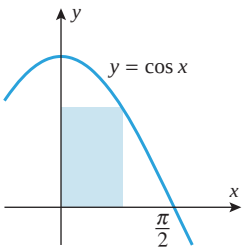
**30.** Use Newton's Method to approximate the absolute maximum of $f(x) = (1 - 2x)\tan^{-1} x$.

**31.** Use Newton's Method to approximate the coordinates of the point on the parabola $y = x^2$ that is closest to the point $(1, 0)$.

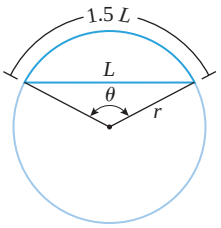
**32.** Use Newton's Method to approximate the dimensions of the rectangle of largest area that can be inscribed under the curve $y = \cos x$ for $0 \le x \le \pi/2$ (Figure Ex-32).

**33.** (a) Show that on a circle of radius $r$, the central angle $\theta$ that subtends an arc whose length is 1.5 times the length $L$ of its chord satisfies the equation $\theta = 3\sin(\theta/2)$ (Figure Ex-33).

(b) Use Newton's Method to approximate $\theta$.

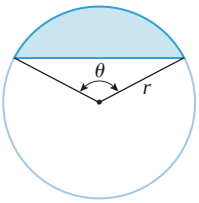


▲ **Figure Ex-32**



▲ **Figure Ex-33**

**34.** A ***segment*** of a circle is the region enclosed by an arc and its chord (Figure Ex-34). If $r$ is the radius of the circle and $\theta$ the angle subtended at the center of the circle, then it can be shown that the area $A$ of the segment is $A = \frac{1}{2}r^2(\theta - \sin\theta)$, where $\theta$ is in radians. Find the value of $\theta$ for which the area of the segment is one-fourth the area of the circle. Give $\theta$ to the nearest degree.



◀ **Figure Ex-34**

**35–36** Use Newton's Method to approximate all real values of $y$ satisfying the given equation for the indicated value of $x$.

**35.** $xy^4 + x^3y = 1;\ x = 1$ **36.** $xy - \cos\left(\frac{1}{2}xy\right) = 0;\ x = 2$

**37.** An ***annuity*** is a sequence of equal payments that are paid or received at regular time intervals. For example, you may want to deposit equal amounts at the end of each year into an interest-bearing account for the purpose of accumulating a lump sum at some future time. If, at the end of each year, interest of $i \times 100\%$ on the account balance for that year is added to the account, then the account is said to pay $i \times 100\%$ interest, ***compounded annually***. It can be shown

that if payments of $Q$ dollars are deposited at the end of each year into an account that pays $i \times 100\%$ compounded annually, then at the time when the $n$th payment and the accrued interest for the past year are deposited, the amount $S(n)$ in the account is given by the formula

$$S(n) = \frac{Q}{i}[(1+i)^n - 1]$$

Suppose that you can invest \$5000 in an interest-bearing account at the end of each year, and your objective is to have \$250,000 on the 25th payment. Approximately what annual compound interest rate must the account pay for you to achieve your goal? [*Hint:* Show that the interest rate $i$ satisfies the equation $50i = (1+i)^{25} - 1$, and solve it using Newton's Method.]

**FOCUS ON CONCEPTS**

**38.** (a) Use a graphing utility to generate the graph of

$$f(x) = \frac{x}{x^2+1}$$

and use it to explain what happens if you apply Newton's Method with a starting value of $x_1 = 2$. Check your conclusion by computing $x_2$, $x_3$, $x_4$, and $x_5$.

(b) Use the graph generated in part (a) to explain what happens if you apply Newton's Method with a starting value of $x_1 = 0.5$. Check your conclusion by computing $x_2$, $x_3$, $x_4$, and $x_5$.

**39.** (a) Apply Newton's Method to $f(x) = x^2 + 1$ with a starting value of $x_1 = 0.5$, and determine if the values of $x_2, \ldots, x_{10}$ appear to converge.

(b) Explain what is happening.

**40.** In each part, explain what happens if you apply Newton's Method to a function $f$ when the given condition is satisfied for some value of $n$.

(a) $f(x_n) = 0$ (b) $x_{n+1} = x_n$

(c) $x_{n+2} = x_n \neq x_{n+1}$

**41. Writing** Compare Newton's Method and the Intermediate-Value Theorem (1.5.7; see Example 5 in Section 1.5) as methods to locate solutions to $f(x) = 0$.

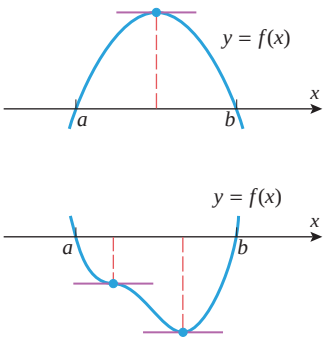
**42. Writing** Newton's Method uses a local linear approximation to $y = f(x)$ at $x = x_n$ to find an "improved" approximation $x_{n+1}$ to a zero of $f$. Your friend proposes a process that uses a local quadratic approximation to $y = f(x)$ at $x = x_n$ (that is, matching values for the function and its first two derivatives) to obtain $x_{n+1}$. Discuss the pros and cons of this proposal. Support your statements with some examples.

## ✔ QUICK CHECK ANSWERS 4.7

**1.** $x_2 \approx 4$, $x_3 \approx 2$ **2.** $\frac{1}{2}$ **3.** $-1$ **4.** $\ln 2 - \frac{1}{2} \approx 0.193147$

# 4.8 ROLLE'S THEOREM; MEAN-VALUE THEOREM

*In this section we will discuss a result called the Mean-Value Theorem. This theorem has so many important consequences that it is regarded as one of the major principles in calculus.*



▲ Figure 4.8.1

## ROLLE'S THEOREM

We will begin with a special case of the Mean-Value Theorem, called Rolle's Theorem, in honor of the mathematician Michel Rolle. This theorem states the geometrically obvious fact that if the graph of a differentiable function intersects the $x$-axis at two places, $a$ and $b$, then somewhere between $a$ and $b$ there must be at least one place where the tangent line is horizontal (Figure 4.8.1). The precise statement of the theorem is as follows.

**4.8.1 THEOREM (*Rolle's Theorem*)** *Let $f$ be continuous on the closed interval $[a, b]$ and differentiable on the open interval $(a, b)$. If*

$$f(a) = 0 \quad \text{and} \quad f(b) = 0$$

*then there is at least one point $c$ in the interval $(a, b)$ such that $f'(c) = 0$.*

**PROOF** We will divide the proof into three cases: the case where $f(x) = 0$ for all $x$ in $(a, b)$, the case where $f(x) > 0$ at some point in $(a, b)$, and the case where $f(x) < 0$ at some point in $(a, b)$.

**CASE 1** If $f(x) = 0$ for all $x$ in $(a, b)$, then $f'(c) = 0$ at every point $c$ in $(a, b)$ because $f$ is a constant function on that interval.

**CASE 2** Assume that $f(x) > 0$ at some point in $(a, b)$. Since $f$ is continuous on $[a, b]$, it follows from the Extreme-Value Theorem (4.4.2) that $f$ has an absolute maximum on $[a, b]$. The absolute maximum value cannot occur at an endpoint of $[a, b]$ because we have assumed that $f(a) = f(b) = 0$, and that $f(x) > 0$ at some point in $(a, b)$. Thus, the absolute maximum must occur at some point $c$ in $(a, b)$. It follows from Theorem 4.4.3 that $c$ is a critical point of $f$, and since $f$ is differentiable on $(a, b)$, this critical point must be a stationary point; that is, $f'(c) = 0$.

**CASE 3** Assume that $f(x) < 0$ at some point in $(a, b)$. The proof of this case is similar to Case 2 and will be omitted. ■

**▶ Example 1** Find the two $x$-intercepts of the function $f(x) = x^2 - 5x + 4$ and confirm that $f'(c) = 0$ at some point $c$ between those intercepts.

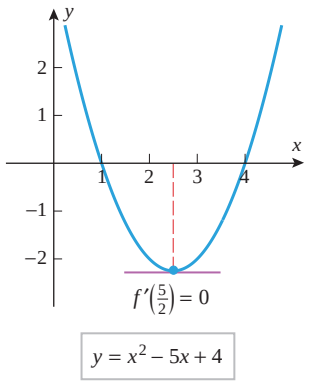
***Solution.*** The function $f$ can be factored as

$$x^2 - 5x + 4 = (x - 1)(x - 4)$$

so the $x$-intercepts are $x = 1$ and $x = 4$. Since the polynomial $f$ is continuous and differentiable everywhere, the hypotheses of Rolle's Theorem are satisfied on the interval $[1, 4]$. Thus, we are guaranteed the existence of at least one point $c$ in the interval $(1, 4)$ such that $f'(c) = 0$. Differentiating $f$ yields

$$f'(x) = 2x - 5$$

Solving the equation $f'(x) = 0$ yields $x = \frac{5}{2}$, so $c = \frac{5}{2}$ is a point in the interval $(1, 4)$ at which $f'(c) = 0$ (Figure 4.8.2). ◀

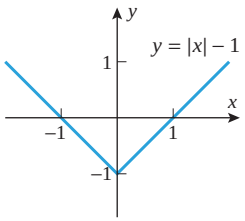


▲ **Figure 4.8.2**

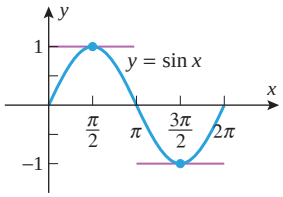
**▶ Example 2** The differentiability requirement in Rolle's Theorem is critical. If $f$ fails to be differentiable at even one place in the interval $(a, b)$, then the conclusion of the

**Michel Rolle (1652–1719)** French mathematician. Rolle, the son of a shopkeeper, received only an elementary education. He married early and as a young man struggled hard to support his family on the meager wages of a transcriber for notaries and attorneys. In spite of his financial problems and minimal education, Rolle studied algebra and Diophantine analysis (a branch of number theory) on his own. Rolle's fortune changed dramatically in 1682 when he published an elegant solution of a difficult, unsolved problem in Diophantine analysis. The public recognition of his achievement led to a patronage under minister Louvois, a job as an elementary mathematics teacher, and eventually to a short-term administrative post in the Ministry of War. In 1685 he joined the Académie des Sciences in a low-level position for which he received no regular salary until 1699. He stayed at the Académie until he died of apoplexy in 1719.

While Rolle's forte was always Diophantine analysis, his most important work was a book on the algebra of equations, called *Traité d'algèbre*, published in 1690. In that book Rolle firmly established the notation $\sqrt[n]{a}$ [earlier written as $\sqrt{(n)\,a}$] for the $n$th root of $a$, and proved a polynomial version of the theorem that today bears his name. (Rolle's Theorem was named by Giusto Bellavitis in 1846.) Ironically, Rolle was one of the most vocal early antagonists of calculus. He strove intently to demonstrate that it gave erroneous results and was based on unsound reasoning. He quarreled so vigorously on the subject that the Académie des Sciences was forced to intervene on several occasions. Among his several achievements, Rolle helped advance the currently accepted size order for negative numbers. Descartes, for example, viewed $-2$ as smaller than $-5$. Rolle preceded most of his contemporaries by adopting the current convention in 1691.



▲ Figure 4.8.3



▲ Figure 4.8.4

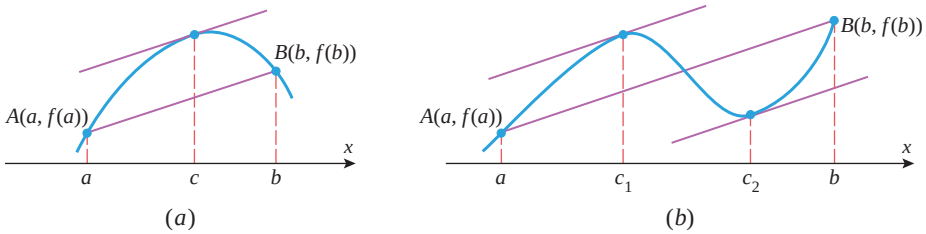
theorem may not hold. For example, the function $f(x) = |x| - 1$ graphed in Figure 4.8.3 has roots at $x = -1$ and $x = 1$, yet there is no horizontal tangent to the graph of $f$ over the interval $(-1, 1)$. ◄

► **Example 3** If $f$ satisfies the conditions of Rolle's Theorem on $[a, b]$, then the theorem guarantees the existence of *at least* one point $c$ in $(a, b)$ at which $f'(c) = 0$. There may, however, be more than one such $c$. For example, the function $f(x) = \sin x$ is continuous and differentiable everywhere, so the hypotheses of Rolle's Theorem are satisfied on the interval $[0, 2\pi]$ whose endpoints are roots of $f$. As indicated in Figure 4.8.4, there are two points in the interval $[0, 2\pi]$ at which the graph of $f$ has a horizontal tangent, $c_1 = \pi/2$ and $c_2 = 3\pi/2$. ◄

## THE MEAN-VALUE THEOREM

Rolle's Theorem is a special case of a more general result, called the ***Mean-Value Theorem***. Geometrically, this theorem states that between any two points $A(a, f(a))$ and $B(b, f(b))$ on the graph of a differentiable function $f$, there is at least one place where the tangent line to the graph is parallel to the secant line joining $A$ and $B$ (Figure 4.8.5).

In Examples 1 and 3 we were able to find exact values of $c$ because the equation $f'(x) = 0$ was easy to solve. However, in the applications of Rolle's Theorem it is usually the *existence of* $c$ that is important and not its actual value.

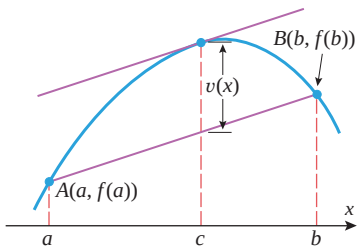


▲ Figure 4.8.5

Note that the slope of the secant line joining $A(a, f(a))$ and $B(b, f(b))$ is

$$\frac{f(b) - f(a)}{b - a}$$

and that the slope of the tangent line at $c$ in Figure 4.8.5*a* is $f'(c)$. Similarly, in Figure 4.8.5*b* the slopes of the tangent lines at $c_1$ and $c_2$ are $f'(c_1)$ and $f'(c_2)$, respectively. Since nonvertical parallel lines have the same slope, the Mean-Value Theorem can be stated precisely as follows.



The tangent line is parallel to the secant line where the vertical distance $v(x)$ between the secant line and the graph of $f$ is maximum.

▲ Figure 4.8.6

**4.8.2 THEOREM (*Mean-Value Theorem*)** *Let $f$ be continuous on the closed interval $[a, b]$ and differentiable on the open interval $(a, b)$. Then there is at least one point $c$ in $(a, b)$ such that*

$$f'(c) = \frac{f(b) - f(a)}{b - a} \tag{1}$$

**MOTIVATION FOR THE PROOF OF THEOREM 4.8.2** Figure 4.8.6 suggests that (1) will hold (i.e., the tangent line will be parallel to the secant line) at a point $c$ where the vertical distance between the curve and the secant line is maximum. Thus, to prove the Mean-Value Theorem it is natural to begin by looking for a formula for the vertical distance $v(x)$ between the curve $y = f(x)$ and the secant line joining $(a, f(a))$ and $(b, f(b))$.

**PROOF OF THEOREM 4.8.2** Since the two-point form of the equation of the secant line joining $(a, f(a))$ and $(b, f(b))$ is

$$y - f(a) = \frac{f(b) - f(a)}{b - a}(x - a)$$

or, equivalently,

$$y = \frac{f(b) - f(a)}{b - a}(x - a) + f(a)$$

the difference $v(x)$ between the height of the graph of $f$ and the height of the secant line is

$$v(x) = f(x) - \left[\frac{f(b) - f(a)}{b - a}(x - a) + f(a)\right] \tag{2}$$

Since $f(x)$ is continuous on $[a, b]$ and differentiable on $(a, b)$, so is $v(x)$. Moreover,

$$v(a) = 0 \quad \text{and} \quad v(b) = 0$$

so that $v(x)$ satisfies the hypotheses of Rolle's Theorem on the interval $[a, b]$. Thus, there is a point $c$ in $(a, b)$ such that $v'(c) = 0$. But from Equation (2)

$$v'(x) = f'(x) - \frac{f(b) - f(a)}{b - a}$$

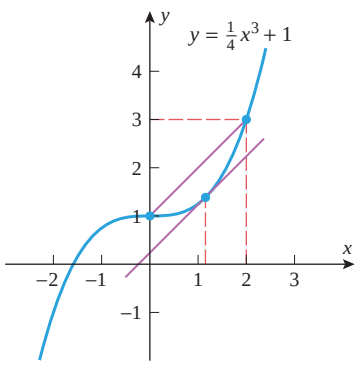
so

$$v'(c) = f'(c) - \frac{f(b) - f(a)}{b - a}$$

Since $v'(c) = 0$, we have

$$f'(c) = \frac{f(b) - f(a)}{b - a} \quad \blacksquare$$

▶ **Example 4** Show that the function $f(x) = \frac{1}{4}x^3 + 1$ satisfies the hypotheses of the Mean-Value Theorem over the interval $[0, 2]$, and find all values of $c$ in the interval $(0, 2)$ at which the tangent line to the graph of $f$ is parallel to the secant line joining the points $(0, f(0))$ and $(2, f(2))$.



▲ Figure 4.8.7

***Solution.*** The function $f$ is continuous and differentiable everywhere because it is a polynomial. In particular, $f$ is continuous on $[0, 2]$ and differentiable on $(0, 2)$, so the hypotheses of the Mean-Value Theorem are satisfied with $a = 0$ and $b = 2$. But

$$f(a) = f(0) = 1, \quad f(b) = f(2) = 3$$

$$f'(x) = \frac{3x^2}{4}, \qquad f'(c) = \frac{3c^2}{4}$$

so in this case Equation (1) becomes

$$\frac{3c^2}{4} = \frac{3 - 1}{2 - 0} \quad \text{or} \quad 3c^2 = 4$$

which has the two solutions $c = \pm 2/\sqrt{3} \approx \pm 1.15$. However, only the positive solution lies in the interval $(0, 2)$; this value of $c$ is consistent with Figure 4.8.7. ◀

## VELOCITY INTERPRETATION OF THE MEAN-VALUE THEOREM

There is a nice interpretation of the Mean-Value Theorem in the situation where $x = f(t)$ is the position versus time curve for a car moving along a straight road. In this case, the right side of (1) is the average velocity of the car over the time interval from $a \le t \le b$, and the left side is the instantaneous velocity at time $t = c$. Thus, the Mean-Value Theorem implies that at least once during the time interval the instantaneous velocity must equal the

average velocity. This agrees with our real-world experience—if the average velocity for a trip is 40 mi/h, then sometime during the trip the speedometer has to read 40 mi/h.

▶ **Example 5** You are driving on a straight highway on which the speed limit is 55 mi/h. At 8:05 A.M. a police car clocks your velocity at 50 mi/h and at 8:10 A.M. a second police car posted 5 mi down the road clocks your velocity at 55 mi/h. Explain why the police have a right to charge you with a speeding violation.

***Solution.*** You traveled 5 mi in 5 min $\left(= \frac{1}{12} \text{ h}\right)$, so your average velocity was 60 mi/h. Therefore, the Mean-Value Theorem guarantees the police that your instantaneous velocity was 60 mi/h at least once over the 5 mi section of highway. ◀

## CONSEQUENCES OF THE MEAN-VALUE THEOREM

We stated at the beginning of this section that the Mean-Value Theorem is the starting point for many important results in calculus. As an example of this, we will use it to prove Theorem 4.1.2, which was one of our fundamental tools for analyzing graphs of functions.

**4.1.2 THEOREM (*Revisited*)** *Let $f$ be a function that is continuous on a closed interval $[a, b]$ and differentiable on the open interval $(a, b)$.*

*(a) If $f'(x) > 0$ for every value of $x$ in $(a, b)$, then $f$ is increasing on $[a, b]$.*

*(b) If $f'(x) < 0$ for every value of $x$ in $(a, b)$, then $f$ is decreasing on $[a, b]$.*

*(c) If $f'(x) = 0$ for every value of $x$ in $(a, b)$, then $f$ is constant on $[a, b]$.*

**PROOF *(a)*** Suppose that $x_1$ and $x_2$ are points in $[a, b]$ such that $x_1 < x_2$. We must show that $f(x_1) < f(x_2)$. Because the hypotheses of the Mean-Value Theorem are satisfied on the entire interval $[a, b]$, they are satisfied on the subinterval $[x_1, x_2]$. Thus, there is some point $c$ in the open interval $(x_1, x_2)$ such that

$$f'(c) = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$$

or, equivalently,

$$f(x_2) - f(x_1) = f'(c)(x_2 - x_1) \tag{3}$$

Since $c$ is in the open interval $(x_1, x_2)$, it follows that $a < c < b$; thus, $f'(c) > 0$. However, $x_2 - x_1 > 0$ since we assumed that $x_1 < x_2$. It follows from (3) that $f(x_2) - f(x_1) > 0$ or, equivalently, $f(x_1) < f(x_2)$, which is what we were to prove. The proofs of parts $(b)$ and $(c)$ are similar and are left as exercises. ■

## THE CONSTANT DIFFERENCE THEOREM

We know from our earliest study of derivatives that the derivative of a constant is zero. Part $(c)$ of Theorem 4.1.2 is the converse of that result; that is, a function whose derivative is zero on an interval must be constant on that interval. If we apply this to the difference of two functions, we obtain the following useful theorem.

**4.8.3 THEOREM (*Constant Difference Theorem*)** *If $f$ and $g$ are differentiable on an interval, and if $f'(x) = g'(x)$ for all $x$ in that interval, then $f - g$ is constant on the interval; that is, there is a constant $k$ such that $f(x) - g(x) = k$ or, equivalently,*

$$f(x) = g(x) + k$$

*for all $x$ in the interval.*

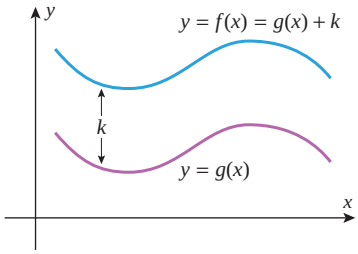
**PROOF** Let $x_1$ and $x_2$ be any points in the interval such that $x_1 < x_2$. Since the functions $f$ and $g$ are differentiable on the interval, they are continuous on the interval. Since $[x_1, x_2]$ is a subinterval, it follows that $f$ and $g$ are continuous on $[x_1, x_2]$ and differentiable on $(x_1, x_2)$. Moreover, it follows from the basic properties of derivatives and continuity that the same is true of the function

$$F(x) = f(x) - g(x)$$

Since

$$F'(x) = f'(x) - g'(x) = 0$$

it follows from part $(c)$ of Theorem 4.1.2 that $F(x) = f(x) - g(x)$ is constant on the interval $[x_1, x_2]$. This means that $f(x) - g(x)$ has the same value at any two points $x_1$ and $x_2$ in the interval, and this implies that $f - g$ is constant on the interval. ■



If $f'(x) = g'(x)$ on an interval, then the graphs of $f$ and $g$ are vertical translations of each other.

▲ **Figure 4.8.8**

Geometrically, the Constant Difference Theorem tells us that if $f$ and $g$ have the same derivative on an interval, then the graphs of $f$ and $g$ are vertical translations of each other over that interval (Figure 4.8.8).

► **Example 6** Part $(c)$ of Theorem 4.1.2 is sometimes useful for establishing identities. For example, although we do not need calculus to prove the identity

$$\sin^{-1} x + \cos^{-1} x = \frac{\pi}{2} \qquad (-1 \le x \le 1) \tag{4}$$

it can be done by letting $f(x) = \sin^{-1} x + \cos^{-1} x$. It follows from Formulas (9) and (10) of Section 3.3 that

$$f'(x) = \frac{d}{dx}[\sin^{-1} x] + \frac{d}{dx}[\cos^{-1} x] = \frac{1}{\sqrt{1-x^2}} - \frac{1}{\sqrt{1-x^2}} = 0$$

so $f(x) = \sin^{-1} x + \cos^{-1} x$ is constant on the interval $[-1, 1]$. We can find this constant by evaluating $f$ at any convenient point in this interval. For example, using $x = 0$ we obtain

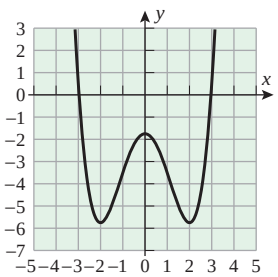
$$f(0) = \sin^{-1} 0 + \cos^{-1} 0 = 0 + \frac{\pi}{2} = \frac{\pi}{2}$$

which proves (4). ◄

## ✔ QUICK CHECK EXERCISES 4.8 (See page 310 for answers.)

**1.** Let $f(x) = x^2 - x$.
(a) An interval on which $f$ satisfies the hypotheses of Rolle's Theorem is _____.
(b) Find all values of $c$ that satisfy the conclusion of Rolle's Theorem for the function $f$ on the interval in part (a).

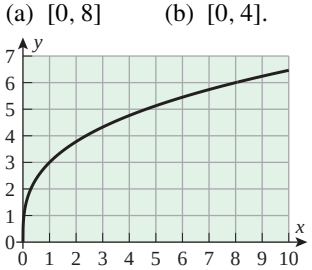
**2.** Use the accompanying graph of $f$ to find an interval $[a, b]$ on which Rolle's Theorem applies, and find all values of $c$ in that interval that satisfy the conclusion of the theorem.



◄ **Figure Ex-2**

**3.** Let $f(x) = x^2 - x$.
(a) Find a point $b$ such that the slope of the secant line through $(0, 0)$ and $(b, f(b))$ is 1.
(b) Find all values of $c$ that satisfy the conclusion of the Mean-Value Theorem for the function $f$ on the interval $[0, b]$, where $b$ is the point found in part (a).

**4.** Use the graph of $f$ in the accompanying figure to estimate all values of $c$ that satisfy the conclusion of the Mean-Value Theorem on the interval
(a) $[0, 8]$ (b) $[0, 4]$.



◄ **Figure Ex-4**

**5.** Find a function $f$ such that the graph of $f$ contains the point $(1, 5)$ and such that for every value of $x_0$ the tangent line to the graph of $f$ at $x_0$ is parallel to the tangent line to the graph of $y = x^2$ at $x_0$.

## EXERCISE SET 4.8 Graphing Utility

**1–4** Verify that the hypotheses of Rolle's Theorem are satisfied on the given interval, and find all values of $c$ in that interval that satisfy the conclusion of the theorem. ■

**1.** $f(x) = x^2 - 8x + 15;\ [3, 5]$

**2.** $f(x) = \frac{1}{2}x - \sqrt{x};\ [0, 4]$

**3.** $f(x) = \cos x;\ [\pi/2, 3\pi/2]$

**4.** $f(x) = \ln(4 + 2x - x^2);\ [-1, 3]$

**5–8** Verify that the hypotheses of the Mean-Value Theorem are satisfied on the given interval, and find all values of $c$ in that interval that satisfy the conclusion of the theorem. ■

**5.** $f(x) = x^2 - x;\ [-3, 5]$

**6.** $f(x) = x^3 + x - 4;\ [-1, 2]$

**7.** $f(x) = \sqrt{25 - x^2};\ [-5, 3]$

**8.** $f(x) = x - \dfrac{1}{x};\ [3, 4]$

**9.** (a) Find an interval $[a, b]$ on which

$$f(x) = x^4 + x^3 - x^2 + x - 2$$

satisfies the hypotheses of Rolle's Theorem.

(b) Generate the graph of $f'(x)$, and use it to make rough estimates of all values of $c$ in the interval obtained in part (a) that satisfy the conclusion of Rolle's Theorem.

(c) Use Newton's Method to improve on the rough estimates obtained in part (b).

**10.** Let $f(x) = x^3 - 4x$.

(a) Find the equation of the secant line through the points $(-2, f(-2))$ and $(1, f(1))$.

(b) Show that there is only one point $c$ in the interval $(-2, 1)$ that satisfies the conclusion of the Mean-Value Theorem for the secant line in part (a).

(c) Find the equation of the tangent line to the graph of $f$ at the point $(c, f(c))$.

(d) Use a graphing utility to generate the secant line in part (a) and the tangent line in part (c) in the same coordinate system, and confirm visually that the two lines seem parallel.

**11–14 True–False** Determine whether the statement is true or false. Explain your answer. ■

**11.** Rolle's Theorem says that if $f$ is a continuous function on $[a, b]$ and $f(a) = f(b)$, then there is a point between $a$ and $b$ at which the curve $y = f(x)$ has a horizontal tangent line.

**12.** If $f$ is continuous on a closed interval $[a, b]$ and differentiable on $(a, b)$, then there is a point between $a$ and $b$ at which the instantaneous rate of change of $f$ matches the average rate of change of $f$ over $[a, b]$.

**13.** The Constant Difference Theorem says that if two functions have derivatives that differ by a constant on an interval, then the functions are equal on the interval.

**14.** One application of the Mean-Value Theorem is to prove that a function with positive derivative on an interval must be increasing on that interval.

### FOCUS ON CONCEPTS

**15.** Let $f(x) = \tan x$.

(a) Show that there is no point $c$ in the interval $(0, \pi)$ such that $f'(c) = 0$, even though $f(0) = f(\pi) = 0$.

(b) Explain why the result in part (a) does not contradict Rolle's Theorem.

**16.** Let $f(x) = x^{2/3}$, $a = -1$, and $b = 8$.

(a) Show that there is no point $c$ in $(a, b)$ such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

(b) Explain why the result in part (a) does not contradict the Mean-Value Theorem.

**17.** (a) Show that if $f$ is differentiable on $(-\infty, +\infty)$, and if $y = f(x)$ and $y = f'(x)$ are graphed in the same coordinate system, then between any two $x$-intercepts of $f$ there is at least one $x$-intercept of $f'$.

(b) Give some examples that illustrate this.

**18.** Review Formulas (8) and (9) in Section 2.1 and use the Mean-Value Theorem to show that if $f$ is differentiable on $(-\infty, +\infty)$, then for any interval $[x_0, x_1]$ there is at least one point in $(x_0, x_1)$ where the instantaneous rate of change of $y$ with respect to $x$ is equal to the average rate of change over the interval.

**19–21** Use the result of Exercise 18 in these exercises. ■

**19.** An automobile travels 4 mi along a straight road in 5 min. Show that the speedometer reads exactly 48 mi/h at least once during the trip.

**20.** At 11 A.M. on a certain morning the outside temperature was 76°F. At 11 P.M. that evening it had dropped to 52°F.

(a) Show that at some instant during this period the temperature was decreasing at the rate of 2°F/h.

(b) Suppose that you know the temperature reached a high of 88°F sometime between 11 A.M. and 11 P.M. Show that at some instant during this period the temperature was decreasing at a rate greater than 3°F/h.

**21.** Suppose that two runners in a 100 m dash finish in a tie. Show that they had the same velocity at least once during the race.

**22.** Use the fact that

$$\frac{d}{dx}[x\ln(2-x)] = \ln(2-x) - \frac{x}{2-x}$$

to show that the equation $x = (2-x)\ln(2-x)$ has at least one solution in the interval $(0, 1)$.

**23.** (a) Use the Constant Difference Theorem (4.8.3) to show that if $f'(x) = g'(x)$ for all $x$ in the interval $(-\infty, +\infty)$, and if $f$ and $g$ have the same value at some point $x_0$, then $f(x) = g(x)$ for all $x$ in $(-\infty, +\infty)$.

(b) Use the result in part (a) to confirm the trigonometric identity $\sin^2 x + \cos^2 x = 1$.

**24.** (a) Use the Constant Difference Theorem (4.8.3) to show that if $f'(x) = g'(x)$ for all $x$ in $(-\infty, +\infty)$, and if $f(x_0) - g(x_0) = c$ at some point $x_0$, then

$$f(x) - g(x) = c$$

for all $x$ in $(-\infty, +\infty)$.

(b) Use the result in part (a) to show that the function

$$h(x) = (x-1)^3 - (x^2+3)(x-3)$$

is constant for all $x$ in $(-\infty, +\infty)$, and find the constant.

(c) Check the result in part (b) by multiplying out and simplifying the formula for $h(x)$.

**25.** Let $g(x) = xe^x - e^x$. Find $f(x)$ so that $f'(x) = g'(x)$ and $f(1) = 2$.

**26.** Let $g(x) = \tan^{-1} x$. Find $f(x)$ so that $f'(x) = g'(x)$ and $f(1) = 2$.

**FOCUS ON CONCEPTS**

**27.** (a) Use the Mean-Value Theorem to show that if $f$ is differentiable on an interval, and if $|f'(x)| \le M$ for all values of $x$ in the interval, then

$$|f(x) - f(y)| \le M|x - y|$$

for all values of $x$ and $y$ in the interval.

(b) Use the result in part (a) to show that

$$|\sin x - \sin y| \le |x - y|$$

for all real values of $x$ and $y$.

**28.** (a) Use the Mean-Value Theorem to show that if $f$ is differentiable on an open interval, and if $|f'(x)| \ge M$ for all values of $x$ in the interval, then

$$|f(x) - f(y)| \ge M|x - y|$$

for all values of $x$ and $y$ in the interval.

(b) Use the result in part (a) to show that

$$|\tan x - \tan y| \ge |x - y|$$

for all values of $x$ and $y$ in the interval $(-\pi/2, \pi/2)$.

(c) Use the result in part (b) to show that

$$|\tan x + \tan y| \ge |x + y|$$

for all values of $x$ and $y$ in the interval $(-\pi/2, \pi/2)$.

**29.** (a) Use the Mean-Value Theorem to show that

$$\sqrt{y} - \sqrt{x} < \frac{y-x}{2\sqrt{x}}$$

if $0 < x < y$.

(b) Use the result in part (a) to show that if $0 < x < y$, then $\sqrt{xy} < \frac{1}{2}(x+y)$.

**30.** Show that if $f$ is differentiable on an open interval and $f'(x) \ne 0$ on the interval, the equation $f(x) = 0$ can have at most one real root in the interval.

**31.** Use the result in Exercise 30 to show the following:

(a) The equation $x^3 + 4x - 1 = 0$ has exactly one real root.

(b) If $b^2 - 3ac < 0$ and if $a \ne 0$, then the equation

$$ax^3 + bx^2 + cx + d = 0$$

has exactly one real root.

**32.** Use the inequality $\sqrt{3} < 1.8$ to prove that

$$1.7 < \sqrt{3} < 1.75$$

[*Hint:* Let $f(x) = \sqrt{x}$, $a = 3$, and $b = 4$ in the Mean-Value Theorem.]

**33.** Use the Mean-Value Theorem to prove that

$$\frac{x}{1+x^2} < \tan^{-1} x < x \quad (x > 0)$$

**34.** (a) Show that if $f$ and $g$ are functions for which

$$f'(x) = g(x) \quad \text{and} \quad g'(x) = f(x)$$

for all $x$, then $f^2(x) - g^2(x)$ is a constant.

(b) Show that the function $f(x) = \frac{1}{2}(e^x + e^{-x})$ and the function $g(x) = \frac{1}{2}(e^x - e^{-x})$ have this property.

**35.** (a) Show that if $f$ and $g$ are functions for which

$$f'(x) = g(x) \quad \text{and} \quad g'(x) = -f(x)$$

for all $x$, then $f^2(x) + g^2(x)$ is a constant.

(b) Give an example of functions $f$ and $g$ with this property.

**FOCUS ON CONCEPTS**

**36.** Let $f$ and $g$ be continuous on $[a, b]$ and differentiable on $(a, b)$. Prove: If $f(a) = g(a)$ and $f(b) = g(b)$, then there is a point $c$ in $(a, b)$ such that $f'(c) = g'(c)$.

**37.** Illustrate the result in Exercise 36 by drawing an appropriate picture.

**38.** (a) Prove that if $f''(x) > 0$ for all $x$ in $(a, b)$, then $f'(x) = 0$ at most once in $(a, b)$.

(b) Give a geometric interpretation of the result in (a).

**39.** (a) Prove part $(b)$ of Theorem 4.1.2.

(b) Prove part $(c)$ of Theorem 4.1.2.

**40.** Use the Mean-Value Theorem to prove the following result: Let $f$ be continuous at $x_0$ and suppose that $\lim_{x \to x_0} f'(x)$ exists. Then $f$ is differentiable at $x_0$, and

$$f'(x_0) = \lim_{x \to x_0} f'(x)$$

[*Hint:* The derivative $f'(x_0)$ is given by

$$f'(x_0) = \lim_{x \to x_0} \frac{f(x) - f(x_0)}{x - x_0}$$

provided this limit exists.]

**FOCUS ON CONCEPTS**

**41.** Let
$$f(x) = \begin{cases} 3x^2, & x \le 1 \\ ax + b, & x > 1 \end{cases}$$
Find the values of $a$ and $b$ so that $f$ will be differentiable at $x = 1$.

**42.** (a) Let
$$f(x) = \begin{cases} x^2, & x \le 0 \\ x^2 + 1, & x > 0 \end{cases}$$
Show that
$$\lim_{x \to 0^-} f'(x) = \lim_{x \to 0^+} f'(x)$$
but that $f'(0)$ does not exist.

(b) Let
$$f(x) = \begin{cases} x^2, & x \le 0 \\ x^3, & x > 0 \end{cases}$$
Show that $f'(0)$ exists but $f''(0)$ does not.

**43.** Use the Mean-Value Theorem to prove the following result: The graph of a function $f$ has a point of vertical tangency at $(x_0, f(x_0))$ if $f$ is continuous at $x_0$ and $f'(x)$ approaches either $+\infty$ or $-\infty$ as $x \to x_0^+$ and as $x \to x_0^-$.

**44.** **Writing** Suppose that $p(x)$ is a nonconstant polynomial with zeros at $x = a$ and $x = b$. Explain how both the Extreme-Value Theorem (4.4.2) and Rolle's Theorem can be used to show that $p$ has a critical point between $a$ and $b$.

**45.** **Writing** Find and describe a physical situation that illustrates the Mean-Value Theorem.

## ✔ QUICK CHECK ANSWERS 4.8

## CHAPTER 4 REVIEW EXERCISES

Graphing Utility C CAS

**1.** (a) If $x_1 < x_2$, what relationship must hold between $f(x_1)$ and $f(x_2)$ if $f$ is increasing on an interval containing $x_1$ and $x_2$? Decreasing? Constant?

(b) What condition on $f'$ ensures that $f$ is increasing on an interval $[a, b]$? Decreasing? Constant?

**2.** (a) What condition on $f'$ ensures that $f$ is concave up on an open interval? Concave down?

(b) What condition on $f''$ ensures that $f$ is concave up on an open interval? Concave down?

(c) In words, what is an inflection point of $f$?

**3–10** Find: (a) the intervals on which $f$ is increasing, (b) the intervals on which $f$ is decreasing, (c) the open intervals on which $f$ is concave up, (d) the open intervals on which $f$ is concave down, and (e) the $x$-coordinates of all inflection points.

**3.** $f(x) = x^2 - 5x + 6$

**4.** $f(x) = x^4 - 8x^2 + 16$

**5.** $f(x) = \dfrac{x^2}{x^2 + 2}$

**6.** $f(x) = \sqrt[3]{x + 2}$

**7.** $f(x) = x^{1/3}(x + 4)$

**8.** $f(x) = x^{4/3} - x^{1/3}$

**9.** $f(x) = 1/e^{x^2}$

**10.** $f(x) = \tan^{-1} x^2$

**11–14** Analyze the trigonometric function $f$ over the specified interval, stating where $f$ is increasing, decreasing, concave up, and concave down, and stating the $x$-coordinates of all inflection points. Confirm that your results are consistent with the graph of $f$ generated with a graphing utility.

**11.** $f(x) = \cos x$; $[0, 2\pi]$

**12.** $f(x) = \tan x$; $(-\pi/2, \pi/2)$

**13.** $f(x) = \sin x \cos x$; $[0, \pi]$

**14.** $f(x) = \cos^2 x - 2 \sin x$; $[0, 2\pi]$

**15.** In each part, sketch a continuous curve $y = f(x)$ with the stated properties.

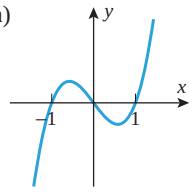
(a) $f(2) = 4$, $f'(2) = 1$, $f''(x) < 0$ for $x < 2$, $f''(x) > 0$ for $x > 2$

(b) $f(2) = 4$, $f''(x) > 0$ for $x < 2$, $f''(x) < 0$ for $x > 2$, $\lim_{x \to 2^-} f'(x) = +\infty$, $\lim_{x \to 2^+} f'(x) = +\infty$

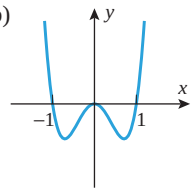
(c) $f(2) = 4$, $f''(x) < 0$ for $x \ne 2$, $\lim_{x \to 2^-} f'(x) = 1$, $\lim_{x \to 2^+} f'(x) = -1$

**16.** In parts (a)–(d), the graph of a polynomial with degree at most 6 is given. Find equations for polynomials that produce graphs with these shapes, and check your answers with a graphing utility.

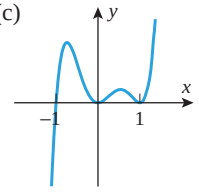
(a)



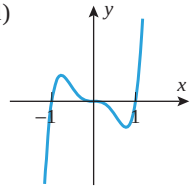
(b)



(c)



(d)



**17.** For a general quadratic polynomial

$$f(x) = ax^2 + bx + c \quad (a \neq 0)$$

find conditions on $a$, $b$, and $c$ to ensure that $f$ is always increasing or always decreasing on $[0, +\infty)$.

**18.** For the general cubic polynomial

$$f(x) = ax^3 + bx^2 + cx + d \quad (a \neq 0)$$

find conditions on $a$, $b$, $c$, and $d$ to ensure that $f$ is always increasing or always decreasing on $(-\infty, +\infty)$.

**19.** Use a graphing utility to estimate the value of $x$ at which

$$f(x) = \frac{2^x}{1 + 2^{x+1}}$$

is increasing most rapidly.

**20.** Prove that for any positive constants $a$ and $k$, the graph of

$$y = \frac{a^x}{1 + a^{x+k}}$$

has an inflection point at $x = -k$.

**21.** (a) Where on the graph of $y = f(x)$ would you expect $y$ to be increasing or decreasing most rapidly with respect to $x$?
(b) In words, what is a relative extremum?
(c) State a procedure for determining where the relative extrema of $f$ occur.

**22.** Determine whether the statement is true or false. If it is false, give an example for which the statement fails.
(a) If $f$ has a relative maximum at $x_0$, then $f(x_0)$ is the largest value that $f(x)$ can have.
(b) If the largest value for $f$ on the interval $(a, b)$ is at $x_0$, then $f$ has a relative maximum at $x_0$.
(c) A function $f$ has a relative extremum at each of its critical points.

**23.** (a) According to the first derivative test, what conditions ensure that $f$ has a relative maximum at $x_0$? A relative minimum?
(b) According to the second derivative test, what conditions ensure that $f$ has a relative maximum at $x_0$? A relative minimum?

**24–26** Locate the critical points and identify which critical points correspond to stationary points. ■

**24.** (a) $f(x) = x^3 + 3x^2 - 9x + 1$
(b) $f(x) = x^4 - 6x^2 - 3$

**25.** (a) $f(x) = \dfrac{x}{x^2 + 2}$ (b) $f(x) = \dfrac{x^2 - 3}{x^2 + 1}$

**26.** (a) $f(x) = x^{1/3}(x - 4)$ (b) $f(x) = x^{4/3} - 6x^{1/3}$

**27.** In each part, find all critical points, and use the first derivative test to classify them as relative maxima, relative minima, or neither.
(a) $f(x) = x^{1/3}(x - 7)^2$
(b) $f(x) = 2\sin x - \cos 2x, \quad 0 \leq x \leq 2\pi$
(c) $f(x) = 3x - (x - 1)^{3/2}$

**28.** In each part, find all critical points, and use the second derivative test (where possible) to classify them as relative maxima, relative minima, or neither.
(a) $f(x) = x^{-1/2} + \frac{1}{9}x^{1/2}$
(b) $f(x) = x^2 + 8/x$
(c) $f(x) = \sin^2 x - \cos x, \quad 0 \leq x \leq 2\pi$

**29–36** Give a graph of the function $f$, and identify the limits as $x \to \pm\infty$, as well as locations of all relative extrema, inflection points, and asymptotes (as appropriate). ■

**29.** $f(x) = x^4 - 3x^3 + 3x^2 + 1$

**30.** $f(x) = x^5 - 4x^4 + 4x^3$

**31.** $f(x) = \tan(x^2 + 1)$

**32.** $f(x) = x - \cos x$

**33.** $f(x) = \dfrac{x^2}{x^2 + 2x + 5}$

**34.** $f(x) = \dfrac{25 - 9x^2}{x^3}$

**35.** $f(x) = \begin{cases} \frac{1}{2}x^2, & x \leq 0 \\ -x^2, & x > 0 \end{cases}$

**36.** $f(x) = (1 + x)^{2/3}(3 - x)^{1/3}$

**37–44** Use any method to find the relative extrema of the function $f$. ■

**37.** $f(x) = x^3 + 5x - 2$

**38.** $f(x) = x^4 - 2x^2 + 7$

**39.** $f(x) = x^{4/5}$

**40.** $f(x) = 2x + x^{2/3}$

**41.** $f(x) = \dfrac{x^2}{x^2 + 1}$

**42.** $f(x) = \dfrac{x}{x + 2}$

**43.** $f(x) = \ln(1 + x^2)$

**44.** $f(x) = x^2 e^x$

**45–46** When using a graphing utility, important features of a graph may be missed if the viewing window is not chosen appropriately. This is illustrated in Exercises 45 and 46. ■

**45.** (a) Generate the graph of $f(x) = \frac{1}{3}x^3 - \frac{1}{400}x$ over the interval $[-5, 5]$, and make a conjecture about the locations and nature of all critical points.
(b) Find the exact locations of all the critical points, and classify them as relative maxima, relative minima, or neither.
(c) Confirm the results in part (b) by graphing $f$ over an appropriate interval.

**46.** (a) Generate the graph of

$$f(x) = \tfrac{1}{5}x^5 - \tfrac{7}{8}x^4 + \tfrac{1}{3}x^3 + \tfrac{7}{2}x^2 - 6x$$

over the interval $[-5, 5]$, and make a conjecture about the locations and nature of all critical points.
(b) Find the exact locations of all the critical points, and classify them as relative maxima, relative minima, or neither.
(c) Confirm the results in part (b) by graphing portions of $f$ over appropriate intervals. [*Note:* It will not be possible to find a single window in which all of the critical points are discernible.]

**47.** (a) Use a graphing utility to generate the graphs of $y = x$ and $y = (x^3 - 8)/(x^2 + 1)$ together over the interval $[-5, 5]$, and make a conjecture about the relationship between the two graphs.
(b) Confirm your conjecture in part (a).

**48.** Use implicit differentiation to show that a function defined implicitly by $\sin x + \cos y = 2y$ has a critical point whenever $\cos x = 0$. Then use either the first or second derivative test to classify these critical points as relative maxima or minima.

**49.** Let

$$f(x) = \frac{2x^3 + x^2 - 15x + 7}{(2x - 1)(3x^2 + x - 1)}$$

Graph $y = f(x)$, and find the equations of all horizontal and vertical asymptotes. Explain why there is no vertical asymptote at $x = \frac{1}{2}$, even though the denominator of $f$ is zero at that point.

**C 50.** Let

$$f(x) = \frac{x^5 - x^4 - 3x^3 + 2x + 4}{x^7 - 2x^6 - 3x^5 + 6x^4 + 4x - 8}$$

(a) Use a CAS to factor the numerator and denominator of $f$, and use the results to determine the locations of all vertical asymptotes.
(b) Confirm that your answer is consistent with the graph of $f$.

**51.** (a) What inequality must $f(x)$ satisfy for the function $f$ to have an absolute maximum on an interval $I$ at $x_0$?
(b) What inequality must $f(x)$ satisfy for $f$ to have an absolute minimum on an interval $I$ at $x_0$?
(c) What is the difference between an absolute extremum and a relative extremum?

**52.** According to the Extreme-Value Theorem, what conditions on a function $f$ and a given interval guarantee that $f$ will have both an absolute maximum and an absolute minimum on the interval?

**53.** In each part, determine whether the statement is true or false, and justify your answer.
(a) If $f$ is differentiable on the open interval $(a, b)$, and if $f$ has an absolute extremum on that interval, then it must occur at a stationary point of $f$.
(b) If $f$ is continuous on the open interval $(a, b)$, and if $f$ has an absolute extremum on that interval, then it must occur at a stationary point of $f$.

**54–56** In each part, find the absolute minimum $m$ and the absolute maximum $M$ of $f$ on the given interval (if they exist), and state where the absolute extrema occur. ■

**54.** (a) $f(x) = 1/x;\ [-2, -1]$
(b) $f(x) = x^3 - x^4;\ \left[-1, \frac{3}{2}\right]$
(c) $f(x) = x - \tan x;\ [-\pi/4, \pi/4]$
(d) $f(x) = -|x^2 - 2x|;\ [1, 3]$

**55.** (a) $f(x) = x^2 - 3x - 1;\ (-\infty, +\infty)$
(b) $f(x) = x^3 - 3x - 2;\ (-\infty, +\infty)$
(c) $f(x) = e^x/x^2;\ (0, +\infty)$
(d) $f(x) = x^x;\ (0, +\infty)$

**56.** (a) $f(x) = 2x^5 - 5x^4 + 7;\ (-1, 3)$
(b) $f(x) = (3 - x)/(2 - x);\ (0, 2)$
(c) $f(x) = 2x/(x^2 + 3);\ (0, 2]$
(d) $f(x) = x^2(x - 2)^{1/3};\ (0, 3]$

**57.** In each part, use a graphing utility to estimate the absolute maximum and minimum values of $f$, if any, on the stated interval, and then use calculus methods to find the exact values.
(a) $f(x) = (x^2 - 1)^2;\ (-\infty, +\infty)$
(b) $f(x) = x/(x^2 + 1);\ [0, +\infty)$
(c) $f(x) = 2\sec x - \tan x;\ [0, \pi/4]$
(d) $f(x) = x/2 + \ln(x^2 + 1);\ [-4, 0]$

**58.** Prove that $x \le \sin^{-1} x$ for all $x$ in $[0, 1]$.

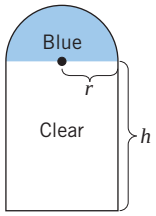
**C 59.** Let

$$f(x) = \frac{x^3 + 2}{x^4 + 1}$$

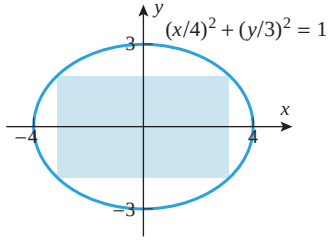
(a) Generate the graph of $y = f(x)$, and use the graph to make rough estimates of the coordinates of the absolute extrema.
(b) Use a CAS to solve the equation $f'(x) = 0$ and then use it to make more accurate approximations of the coordinates in part (a).

**60.** A church window consists of a blue semicircular section surmounting a clear rectangular section as shown in the accompanying figure. The blue glass lets through half as much light per unit area as the clear glass. Find the radius $r$ of the window that admits the most light if the perimeter of the entire window is to be $P$ feet.

**61.** Find the dimensions of the rectangle of maximum area that can be inscribed inside the ellipse $(x/4)^2 + (y/3)^2 = 1$ (see the accompanying figure).



▲ Figure Ex-60

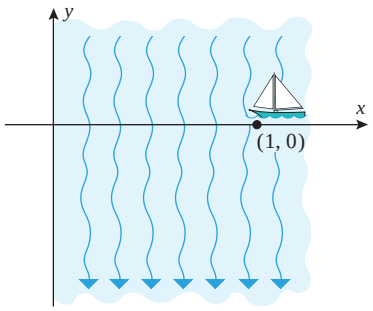


▲ Figure Ex-61

**C 62.** As shown in the accompanying figure on the next page, suppose that a boat enters the river at the point $(1, 0)$ and maintains a heading toward the origin. As a result of the strong current, the boat follows the path

$$y = \frac{x^{10/3} - 1}{2x^{2/3}}$$

where $x$ and $y$ are in miles.
(a) Graph the path taken by the boat.
(b) Can the boat reach the origin? If not, discuss its fate and find how close it comes to the origin.



◀ Figure Ex-62

**63.** A sheet of cardboard 12 in square is used to make an open box by cutting squares of equal size from the four corners and folding up the sides. What size squares should be cut to obtain a box with largest possible volume?

**64.** Is it true or false that a particle in rectilinear motion is speeding up when its velocity is increasing and slowing down when its velocity is decreasing? Justify your answer.

**65.** (a) Can an object in rectilinear motion reverse direction if its acceleration is constant? Justify your answer using a velocity versus time curve.

(b) Can an object in rectilinear motion have increasing speed and decreasing acceleration? Justify your answer using a velocity versus time curve.

**66.** Suppose that the position function of a particle in rectilinear motion is given by the formula $s(t) = t/(2t^2 + 8)$ for $t \geq 0$.

(a) Use a graphing utility to generate the position, velocity, and acceleration versus time curves.

(b) Use the appropriate graph to make a rough estimate of the time when the particle reverses direction, and then find that time exactly.

(c) Find the position, velocity, and acceleration at the instant when the particle reverses direction.

(d) Use the appropriate graphs to make rough estimates of the time intervals on which the particle is speeding up and the time intervals on which it is slowing down, and then find those time intervals exactly.

(e) When does the particle have its maximum and minimum velocities?

**67.** For parts (a)–(f), suppose that the position function of a particle in rectilinear motion is given by the formula

$$s(t) = \frac{t^2 + 1}{t^4 + 1}, \quad t \geq 0$$

(a) Use a CAS to find simplified formulas for the velocity function $v(t)$ and the acceleration function $a(t)$.

(b) Graph the position, velocity, and acceleration versus time curves.

(c) Use the appropriate graph to make a rough estimate of the time at which the particle is farthest from the origin and its distance from the origin at that time.

(d) Use the appropriate graph to make a rough estimate of the time interval during which the particle is moving in the positive direction.

(e) Use the appropriate graphs to make rough estimates of the time intervals during which the particle is speeding up and the time intervals during which it is slowing down.

(f) Use the appropriate graph to make a rough estimate of the maximum speed of the particle and the time at which the maximum speed occurs.

**68.** Draw an appropriate picture, and describe the basic idea of Newton's Method without using any formulas.

**69.** Use Newton's Method to approximate all three solutions of $x^3 - 4x + 1 = 0$.

**70.** Use Newton's Method to approximate the smallest positive solution of $\sin x + \cos x = 0$.

**71.** Use a graphing utility to determine the number of times the curve $y = x^3$ intersects the curve $y = (x/2) - 1$. Then apply Newton's Method to approximate the $x$-coordinates of all intersections.

**72.** According to ***Kepler's law***, the planets in our solar system move in elliptical orbits around the Sun. If a planet's closest approach to the Sun occurs at time $t = 0$, then the distance $r$ from the center of the planet to the center of the Sun at some later time $t$ can be determined from the equation

$$r = a(1 - e\cos\phi)$$

where $a$ is the average distance between centers, $e$ is a positive constant that measures the "flatness" of the elliptical orbit, and $\phi$ is the solution of *Kepler's equation*

$$\frac{2\pi t}{T} = \phi - e\sin\phi$$

in which $T$ is the time it takes for one complete orbit of the planet. Estimate the distance from the Earth to the Sun when $t = 90$ days. [First find $\phi$ from Kepler's equation, and then use this value of $\phi$ to find the distance. Use $a = 150 \times 10^6$ km, $e = 0.0167$, and $T = 365$ days.]

**73.** Using the formulas in Exercise 72, find the distance from the planet Mars to the Sun when $t = 1$ year. For Mars use $a = 228 \times 10^6$ km, $e = 0.0934$, and $T = 1.88$ years.

**74.** Suppose that $f$ is continuous on the closed interval $[a, b]$ and differentiable on the open interval $(a, b)$, and suppose that $f(a) = f(b)$. Is it true or false that $f$ must have at least one stationary point in $(a, b)$? Justify your answer.

**75.** In each part, determine whether all of the hypotheses of Rolle's Theorem are satisfied on the stated interval. If not, state which hypotheses fail; if so, find all values of $c$ guaranteed in the conclusion of the theorem.

(a) $f(x) = \sqrt{4 - x^2}$ on $[-2, 2]$

(b) $f(x) = x^{2/3} - 1$ on $[-1, 1]$

(c) $f(x) = \sin(x^2)$ on $[0, \sqrt{\pi}\,]$

**76.** In each part, determine whether all of the hypotheses of the Mean-Value Theorem are satisfied on the stated interval. If not, state which hypotheses fail; if so, find all values of $c$ guaranteed in the conclusion of the theorem.

(a) $f(x) = |x - 1|$ on $[-2, 2]$ *(cont.)*

(b) $f(x) = \dfrac{x+1}{x-1}$ on $[2, 3]$

(c) $f(x) = \begin{cases} 3 - x^2 & \text{if } x \le 1 \\ 2/x & \text{if } x > 1 \end{cases}$ on $[0, 2]$

**77.** Use the fact that

$$\frac{d}{dx}(x^6 - 2x^2 + x) = 6x^5 - 4x + 1$$

to show that the equation $6x^5 - 4x + 1 = 0$ has at least one solution in the interval $(0, 1)$.

**78.** Let $g(x) = x^3 - 4x + 6$. Find $f(x)$ so that $f'(x) = g'(x)$ and $f(1) = 2$.

## CHAPTER 4 MAKING CONNECTIONS

**1.** Suppose that $g(x)$ is a function that is defined and differentiable for all real numbers $x$ and that $g(x)$ has the following properties:

(i) $g(0) = 2$ and $g'(0) = -\frac{2}{3}$.
(ii) $g(4) = 3$ and $g'(4) = 3$.
(iii) $g(x)$ is concave up for $x < 4$ and concave down for $x > 4$.
(iv) $g(x) \ge -10$ for all $x$.

Use these properties to answer the following questions.

(a) How many zeros does $g$ have?
(b) How many zeros does $g'$ have?
(c) Exactly one of the following limits is possible:

$$\lim_{x \to +\infty} g'(x) = -5, \quad \lim_{x \to +\infty} g'(x) = 0, \quad \lim_{x \to +\infty} g'(x) = 5$$

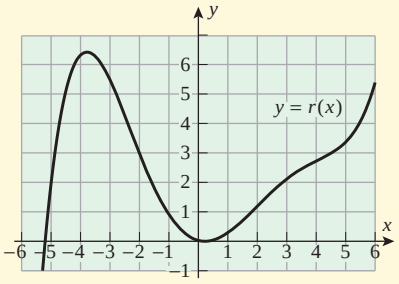
Identify which of these results is possible and draw a rough sketch of the graph of such a function $g(x)$. Explain why the other two results are impossible.

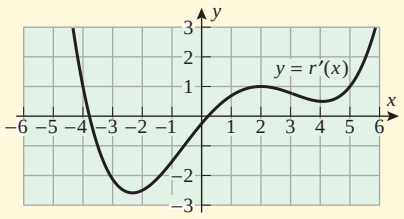
**2.** The two graphs in the accompanying figure depict a function $r(x)$ and its derivative $r'(x)$.

(a) Approximate the coordinates of each inflection point on the graph of $y = r(x)$.
(b) Suppose that $f(x)$ is a function that is continuous everywhere and whose *derivative* satisfies

$$f'(x) = (x^2 - 4) \cdot r(x)$$

What are the critical points for $f(x)$? At each critical point, identify whether $f(x)$ has a (relative) maximum, minimum, or neither a maximum or minimum. Approximate $f''(1)$.





◀ **Figure Ex-2**

**3.** With the function $r(x)$ as provided in Exercise 2, let $g(x)$ be a function that is continuous everywhere such that $g'(x) = x - r(x)$. For which values of $x$ does $g(x)$ have an inflection point?

**4.** Suppose that $f$ is a function whose derivative is continuous everywhere. Assume that there exists a real number $c$ such that when Newton's Method is applied to $f$, the inequality

$$|x_n - c| < \frac{1}{n}$$

is satisfied for all values of $n = 1, 2, 3, \ldots$.

(a) Explain why

$$|x_{n+1} - x_n| < \frac{2}{n}$$

for all values of $n = 1, 2, 3, \ldots$.

(b) Show that there exists a positive constant $M$ such that

$$|f(x_n)| \le M|x_{n+1} - x_n| < \frac{2M}{n}$$

for all values of $n = 1, 2, 3, \ldots$.

(c) Prove that if $f(c) \ne 0$, then there exists a positive integer $N$ such that

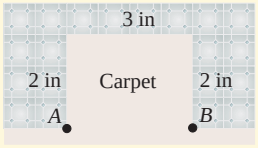
$$\frac{|f(c)|}{2} < |f(x_n)|$$

if $n > N$. [*Hint:* Argue that $f(x) \to f(c)$ as $x \to c$ and then apply Definition 1.4.1 with $\epsilon = \frac{1}{2}|f(c)|$.]

(d) What can you conclude from parts (b) and (c)?

**5.** What are the important elements in the argument suggested by Exercise 4? Can you extend this argument to a wider collection of functions?

**6.** A bug crawling on a linoleum floor along the edge of a plush carpet encounters an irregularity in the form of a 2 in by 3 in rectangular section of carpet that juts out into the linoleum as illustrated in Figure Ex-6a on the next page.



◀ **Figure Ex-6a**

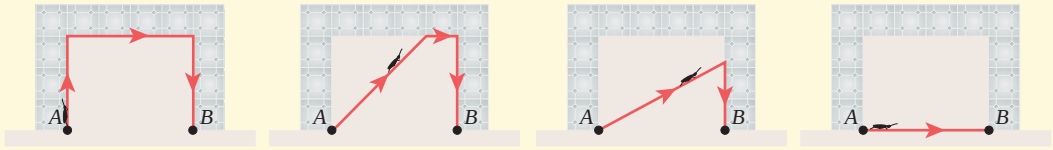
The bug crawls at 0.7 in/s on the linoleum, but only at 0.3 in/s through the carpet, and its goal is to travel from point $A$ to point $B$. Four possible routes from $A$ to $B$ are as follows: (i) crawl on linoleum along the edge of the carpet; (ii) crawl through the carpet to a point on the wider side of the rectangle, and finish the journey on linoleum along the edge of the carpet; (iii) crawl through the carpet to a point on the shorter side of the rectangle, and finish the journey on linoleum along the edge of the carpet; or (iv) crawl through the carpet directly to point $B$. (See Figure Ex-6b.)

(a) Calculate the times it would take the bug to crawl from $A$ to $B$ via routes (i) and (iv).

(b) Suppose the bug follows route (ii) and use $x$ to represent the total distance the bug crawls on linoleum. Identify the appropriate interval for $x$ in this case, and determine the shortest time for the bug to complete the journey using route (ii).

(c) Suppose the bug follows route (iii) and again use $x$ to represent the total distance the bug crawls on linoleum. Identify the appropriate interval for $x$ in this case, and determine the shortest time for the bug to complete the journey using route (iii).

(d) Which of routes (i), (ii), (iii), or (iv) is quickest? What is the shortest time for the bug to complete the journey?



(i) (ii) (iii) (iv)

# 5 INTEGRATION

Jon Ferrey/Allsport/Getty Images

*If a dragster moves with varying velocity over a certain time interval, it is possible to find the distance it travels during that time interval using techniques of calculus.*

In this chapter we will begin with an overview of the problem of finding areas—we will discuss what the term "area" means, and we will outline two approaches to defining and calculating areas. Following this overview, we will discuss the Fundamental Theorem of Calculus, which is the theorem that relates the problems of finding tangent lines and areas, and we will discuss techniques for calculating areas. We will then use the ideas in this chapter to define the average value of a function, to continue our study of rectilinear motion, and to examine some consequences of the chain rule in integral calculus. We conclude the chapter by studying functions defined by integrals, with a focus on the natural logarithm function.

## 5.1 AN OVERVIEW OF THE AREA PROBLEM

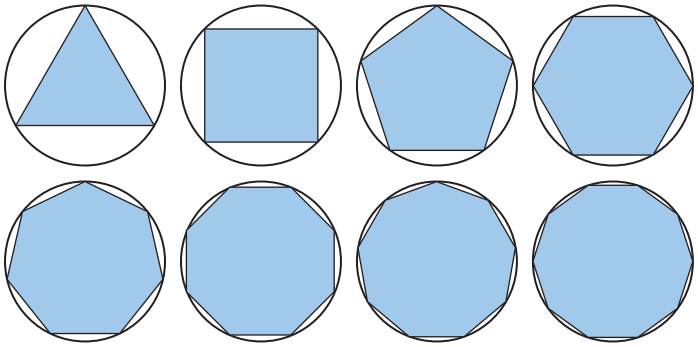
*In this introductory section we will consider the problem of calculating areas of plane regions with curvilinear boundaries. All of the results in this section will be reexamined in more detail later in this chapter. Our purpose here is simply to introduce and motivate the fundamental concepts.*

### THE AREA PROBLEM

Formulas for the areas of polygons, such as squares, rectangles, triangles, and trapezoids, were well known in many early civilizations. However, the problem of finding formulas for regions with curved boundaries (a circle being the simplest example) caused difficulties for early mathematicians.

The first real progress in dealing with the general area problem was made by the Greek mathematician Archimedes, who obtained areas of regions bounded by circular arcs, parabolas, spirals, and various other curves using an ingenious procedure that was later called the *method of exhaustion*. The method, when applied to a circle, consists of inscribing a succession of regular polygons in the circle and allowing the number of sides to increase indefinitely (Figure 5.1.1). As the number of sides increases, the polygons tend to "exhaust" the region inside the circle, and the areas of the polygons become better and better approximations of the exact area of the circle.

To see how this works numerically, let $A(n)$ denote the area of a regular $n$-sided polygon inscribed in a circle of radius 1. Table 5.1.1 shows the values of $A(n)$ for various choices of $n$. Note that for large values of $n$ the area $A(n)$ appears to be close to $\pi$ (square units),



▲ Figure 5.1.1

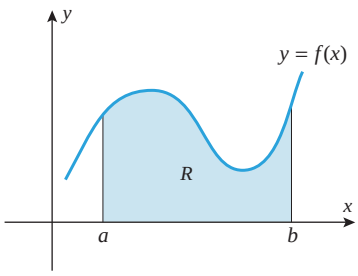
**Table 5.1.1**

| $n$ | $A(n)$ |
|---|---|
| 100 | 3.13952597647 |
| 200 | 3.14107590781 |
| 300 | 3.14136298250 |
| 400 | 3.14146346236 |
| 500 | 3.14150997084 |
| 1000 | 3.14157198278 |
| 2000 | 3.14158748588 |
| 3000 | 3.14159035683 |
| 4000 | 3.14159136166 |
| 5000 | 3.14159182676 |
| 10,000 | 3.14159244688 |

as one would expect. This suggests that for a circle of radius 1, the method of exhaustion is equivalent to an equation of the form

$$\lim_{n\to\infty} A(n) = \pi$$

Since Greek mathematicians were suspicious of the concept of "infinity," they avoided its use in mathematical arguments. As a result, computation of area using the method of exhaustion was a very cumbersome procedure. It remained for Newton and Leibniz to obtain a general method for finding areas that explicitly used the notion of a limit. We will discuss their method in the context of the following problem.

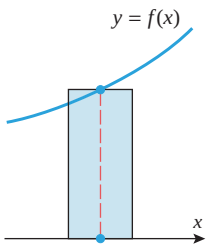


▲ Figure 5.1.2

**5.1.1 THE AREA PROBLEM** Given a function $f$ that is continuous and nonnegative on an interval $[a, b]$, find the area between the graph of $f$ and the interval $[a, b]$ on the $x$-axis (Figure 5.1.2).

## THE RECTANGLE METHOD FOR FINDING AREAS

One approach to the area problem is to use Archimedes' method of exhaustion in the following way:



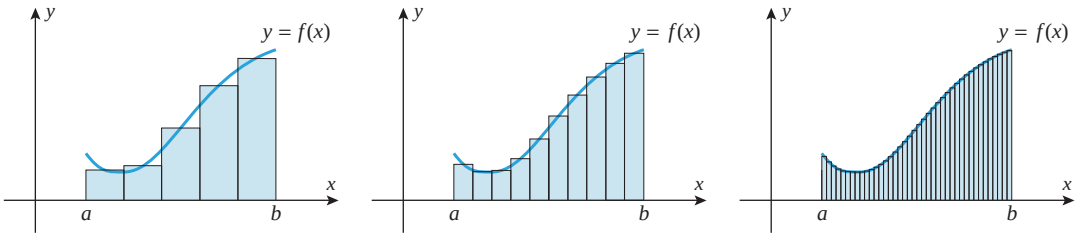
▲ Figure 5.1.3

- Divide the interval $[a, b]$ into $n$ equal subintervals, and over each subinterval construct a rectangle that extends from the $x$-axis to any point on the curve $y = f(x)$ that is above the subinterval; the particular point does not matter—it can be above the center, above an endpoint, or above any other point in the subinterval. In Figure 5.1.3 it is above the center.
- For each $n$, the total area of the rectangles can be viewed as an *approximation* to the exact area under the curve over the interval $[a, b]$. Moreover, it is evident intuitively that as $n$ increases these approximations will get better and better and will approach the exact area as a limit (Figure 5.1.4). That is, if $A$ denotes the exact area under the curve and $A_n$ denotes the approximation to $A$ using $n$ rectangles, then

$$A = \lim_{n\to+\infty} A_n$$

We will call this the ***rectangle method*** for computing $A$.

Logically speaking, we cannot really talk about computing areas without a precise mathematical definition of the term "area." Later in this chapter we will give such a definition, but for now we will treat the concept intuitively.



▲ **Figure 5.1.4**

To illustrate this idea, we will use the rectangle method to approximate the area under the curve $y = x^2$ over the interval $[0, 1]$ (Figure 5.1.5). We will begin by dividing the interval $[0, 1]$ into $n$ equal subintervals, from which it follows that each subinterval has length $1/n$; the endpoints of the subintervals occur at

$$0, \quad \frac{1}{n}, \quad \frac{2}{n}, \quad \frac{3}{n}, \ldots, \quad \frac{n-1}{n}, \quad 1$$

**Archimedes (287 B.C.–212 B.C.)** Greek mathematician and scientist. Born in Syracuse, Sicily, Archimedes was the son of the astronomer Pheidias and possibly related to Heiron II, king of Syracuse. Most of the facts about his life come from the Roman biographer, Plutarch, who inserted a few tantalizing pages about him in the massive biography of the Roman soldier, Marcellus. In the words of one writer, "the account of Archimedes is slipped like a tissue-thin shaving of ham in a bull-choking sandwich."

Archimedes ranks with Newton and Gauss as one of the three greatest mathematicians who ever lived, and he is certainly the greatest mathematician of antiquity. His mathematical work is so modern in spirit and technique that it is barely distinguishable from that of a seventeenth-century mathematician, yet it was all done without benefit of algebra or a convenient number system. Among his mathematical achievements, Archimedes developed a general method (exhaustion) for finding areas and volumes, and he used the method to find areas bounded by parabolas and spirals and to find volumes of cylinders, paraboloids, and segments of spheres. He gave a procedure for approximating $\pi$ and bounded its value between $3\frac{10}{71}$ and $3\frac{1}{7}$. In spite of the limitations of the Greek numbering system, he devised methods for finding square roots and invented a method based on the Greek myriad (10,000) for representing numbers as large as 1 followed by 80 million billion zeros.

Of all his mathematical work, Archimedes was most proud of his discovery of a method for finding the volume of a sphere—he showed that the volume of a sphere is two-thirds the volume of the smallest cylinder that can contain it. At his request, the figure of a sphere and cylinder was engraved on his tombstone.

In addition to mathematics, Archimedes worked extensively in mechanics and hydrostatics. Nearly every schoolchild knows Archimedes as the absent-minded scientist who, on realizing that a floating object displaces its weight of liquid, leaped from his bath and ran naked through the streets of Syracuse shouting, "Eureka, Eureka!"—(meaning, "I have found it!"). Archimedes actually created the discipline of hydrostatics and used it to find equilibrium positions for various floating bodies. He laid down the fundamental postulates of mechanics, discovered the laws of levers, and calculated centers of gravity for various flat surfaces and solids. In the excitement of discovering the mathematical laws of the lever, he is said to have declared, "Give me a place to stand and I will move the earth."

Although Archimedes was apparently more interested in pure mathematics than its applications, he was an engineering genius. During the second Punic war, when Syracuse was attacked by the Roman fleet under the command of Marcellus, it was reported by Plutarch that Archimedes' military inventions held the fleet at bay for three years. He invented super catapults that showered the Romans with rocks weighing a quarter ton or more, and fearsome mechanical devices with iron "beaks and claws" that reached over the city walls, grasped the ships, and spun them against the rocks. After the first repulse, Marcellus called Archimedes a "geometrical Briareus (a hundred-armed mythological monster) who uses our ships like cups to ladle water from the sea."

Eventually the Roman army was victorious and contrary to Marcellus' specific orders the 75-year-old Archimedes was killed by a Roman soldier. According to one report of the incident, the soldier cast a shadow across the sand in which Archimedes was working on a mathematical problem. When the annoyed Archimedes yelled, "Don't disturb my circles," the soldier flew into a rage and cut the old man down.

Although there is no known likeness or statue of this great man, nine works of Archimedes have survived to the present day. Especially important is his treatise, *The Method of Mechanical Theorems*, which was part of a palimpsest found in Constantinople in 1906. In this treatise Archimedes explains how he made some of his discoveries, using reasoning that anticipated ideas of the integral calculus. Thought to be lost, the Archimedes palimpsest later resurfaced in 1998, when it was purchased by an anonymous private collector for two million dollars.

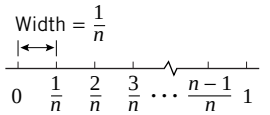
▲ Figure 5.1.5



Subdivision of [0, 1] into $n$ subintervals of equal length

▲ Figure 5.1.6

(Figure 5.1.6). We want to construct a rectangle over each of these subintervals whose height is the value of the function $f(x) = x^2$ at some point in the subinterval. To be specific, let us use the right endpoints, in which case the heights of our rectangles will be

$$\left(\frac{1}{n}\right)^2, \quad \left(\frac{2}{n}\right)^2, \quad \left(\frac{3}{n}\right)^2, \ldots, \quad 1^2$$

and since each rectangle has a base of width $1/n$, the total area $A_n$ of the $n$ rectangles will be

$$A_n = \left[\left(\frac{1}{n}\right)^2 + \left(\frac{2}{n}\right)^2 + \left(\frac{3}{n}\right)^2 + \cdots + 1^2\right]\left(\frac{1}{n}\right) \tag{1}$$

For example, if $n = 4$, then the total area of the four approximating rectangles would be

$$A_4 = \left[\left(\tfrac{1}{4}\right)^2 + \left(\tfrac{2}{4}\right)^2 + \left(\tfrac{3}{4}\right)^2 + 1^2\right]\left(\tfrac{1}{4}\right) = \tfrac{15}{32} = 0.46875$$

Table 5.1.2 shows the result of evaluating (1) on a computer for some increasingly large values of $n$. These computations suggest that the exact area is close to $\frac{1}{3}$. Later in this chapter we will prove that this area is exactly $\frac{1}{3}$ by showing that

$$\lim_{n\to\infty} A_n = \tfrac{1}{3}$$

**TECHNOLOGY MASTERY**

Use a calculating utility to compute the value of $A_{10}$ in Table 5.1.2. Some calculating utilities have special commands for computing sums such as that in (1) for any specified value of $n$. If your utility has this feature, use it to compute $A_{100}$ as well.

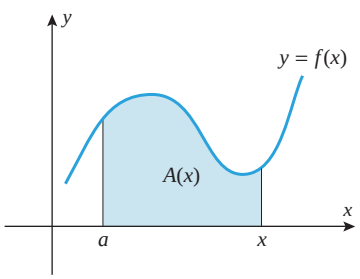
**Table 5.1.2**

| $n$ | 4 | 10 | 100 | 1000 | 10,000 | 100,000 |
|---|---|---|---|---|---|---|
| $A_n$ | 0.468750 | 0.385000 | 0.338350 | 0.333834 | 0.333383 | 0.333338 |

## THE ANTIDERIVATIVE METHOD FOR FINDING AREAS

Although the rectangle method is appealing intuitively, the limits that result can only be evaluated in certain cases. For this reason, progress on the area problem remained at a rudimentary level until the latter part of the seventeenth century when Isaac Newton and Gottfried Leibniz independently discovered a fundamental relationship between areas and derivatives. Briefly stated, they showed that if $f$ is a nonnegative continuous function on the interval $[a, b]$, and if $A(x)$ denotes the area under the graph of $f$ over the interval $[a, x]$, where $x$ is any point in the interval $[a, b]$ (Figure 5.1.7), then

$$A'(x) = f(x) \tag{2}$$



▲ Figure 5.1.7

The following example confirms Formula (2) in some cases where a formula for $A(x)$ can be found using elementary geometry.

**▶ Example 1** For each of the functions $f$, find the area $A(x)$ between the graph of $f$ and the interval $[a, x] = [-1, x]$, and find the derivative $A'(x)$ of this area function.

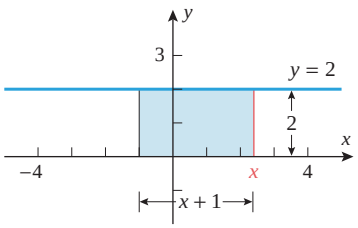
(a) $f(x) = 2$ (b) $f(x) = x + 1$ (c) $f(x) = 2x + 3$

***Solution (a).*** From Figure 5.1.8*a* we see that

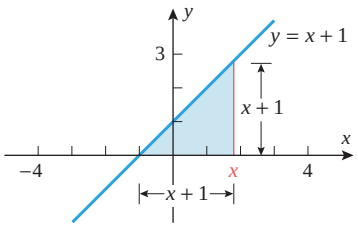
$$A(x) = 2(x - (-1)) = 2(x + 1) = 2x + 2$$

is the area of a rectangle of height 2 and base $x + 1$. For this area function,

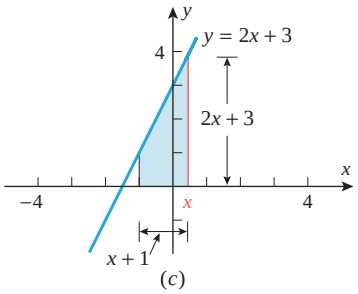
$$A'(x) = 2 = f(x)$$



(a)



(b)



(c)

▲ **Figure 5.1.8**

How does the solution to Example 2 change if the interval [0, 1] is replaced by the interval [−1, 1]?

***Solution (b).*** From Figure 5.1.8*b* we see that

$$A(x) = \frac{1}{2}(x+1)(x+1) = \frac{x^2}{2} + x + \frac{1}{2}$$

is the area of an isosceles right triangle with base and height equal to $x + 1$. For this area function,

$$A'(x) = x + 1 = f(x)$$

***Solution (c).*** Recall that the formula for the area of a trapezoid is $A = \frac{1}{2}(b + b')h$, where $b$ and $b'$ denote the lengths of the parallel sides of the trapezoid, and the altitude $h$ denotes the distance between the parallel sides. From Figure 5.1.8*c* we see that

$$A(x) = \tfrac{1}{2}((2x+3)+1)(x-(-1)) = x^2 + 3x + 2$$

is the area of a trapezoid with parallel sides of lengths 1 and $2x + 3$ and with altitude $x - (-1) = x + 1$. For this area function,

$$A'(x) = 2x + 3 = f(x) \quad \blacktriangleleft$$

Formula (2) is important because it relates the area function $A$ and the region-bounding function $f$. Although a formula for $A(x)$ may be difficult to obtain directly, its derivative, $f(x)$, is given. If a formula for $A(x)$ can be recovered from the given formula for $A'(x)$, then the area under the graph of $f$ over the interval $[a, b]$ can be obtained by computing $A(b)$.

The process of finding a function from its derivative is called ***antidifferentiation***, and a procedure for finding areas via antidifferentiation is called the ***antiderivative method***. To illustrate this method, let us revisit the problem of finding the area in Figure 5.1.5.

▶ **Example 2** Use the antiderivative method to find the area under the graph of $y = x^2$ over the interval $[0, 1]$.

***Solution.*** Let $x$ be any point in the interval $[0, 1]$, and let $A(x)$ denote the area under the graph of $f(x) = x^2$ over the interval $[0, x]$. It follows from (2) that

$$A'(x) = x^2 \tag{3}$$

To find $A(x)$ we must look for a function whose derivative is $x^2$. By guessing, we see that one such function is $\frac{1}{3}x^3$, so by Theorem 4.8.3

$$A(x) = \tfrac{1}{3}x^3 + C \tag{4}$$

for some real constant $C$. We can determine the specific value for $C$ by considering the case where $x = 0$. In this case (4) implies that

$$A(0) = C \tag{5}$$

But if $x = 0$, then the interval $[0, x]$ reduces to a single point. If we agree that the area above a single point should be taken as zero, then $A(0) = 0$ and (5) implies that $C = 0$. Thus, it follows from (4) that

$$A(x) = \tfrac{1}{3}x^3$$

is the area function we are seeking. This implies that the area under the graph of $y = x^2$ over the interval $[0, 1]$ is

$$A(1) = \tfrac{1}{3}(1^3) = \tfrac{1}{3}$$

This is consistent with the result that we previously obtained numerically. ◀

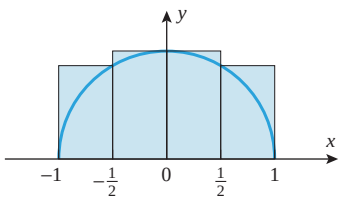
As Example 2 illustrates, antidifferentiation is a process in which one tries to "undo" a differentiation. One of the objectives in this chapter is to develop efficient antidifferentiation procedures.

### THE RECTANGLE METHOD AND THE ANTIDERIVATIVE METHOD COMPARED

The rectangle method and the antiderivative method provide two very different approaches to the area problem, each of which is important. The antiderivative method is usually the more efficient way to *compute* areas, but it is the rectangle method that is used to formally *define* the notion of area, thereby allowing us to prove mathematical results about areas. The underlying idea of the rectangle approach is also important because it can be adapted readily to such diverse problems as finding the volume of a solid, the length of a curve, the mass of an object, and the work done in pumping water out of a tank, to name a few.

## ✔ QUICK CHECK EXERCISES 5.1 (See page 322 for answers.)

**1.** Let $R$ denote the region below the graph of $f(x) = \sqrt{1 - x^2}$ and above the interval $[-1, 1]$.
(a) Use a geometric argument to find the area of $R$.
(b) What estimate results if the area of $R$ is approximated by the total area within the rectangles of the accompanying figure?



◀ **Figure Ex-1**

**2.** Suppose that when the area $A$ between the graph of a function $y = f(x)$ and an interval $[a, b]$ is approximated by the areas of $n$ rectangles, the total area of the rectangles is $A_n = 2 + (2/n)$, $n = 1, 2, \ldots$. Then, $A =$ _____.

**3.** The area under the graph of $y = x^2$ over the interval $[0, 3]$ is _____.

**4.** Find a formula for the area $A(x)$ between the graph of the function $f(x) = x$ and the interval $[0, x]$, and verify that $A'(x) = f(x)$.

**5.** The area under the graph of $y = f(x)$ over the interval $[0, x]$ is $A(x) = x + e^x - 1$. It follows that $f(x) =$ _____.

## EXERCISE SET 5.1

**1–12** Estimate the area between the graph of the function $f$ and the interval $[a, b]$. Use an approximation scheme with $n$ rectangles similar to our treatment of $f(x) = x^2$ in this section. If your calculating utility will perform automatic summations, estimate the specified area using $n = 10$, 50, and 100 rectangles. Otherwise, estimate this area using $n = 2$, 5, and 10 rectangles. ■

**1.** $f(x) = \sqrt{x}$; $[a, b] = [0, 1]$

**2.** $f(x) = \dfrac{1}{x + 1}$; $[a, b] = [0, 1]$

**3.** $f(x) = \sin x$; $[a, b] = [0, \pi]$

**4.** $f(x) = \cos x$; $[a, b] = [0, \pi/2]$

**5.** $f(x) = \dfrac{1}{x}$; $[a, b] = [1, 2]$

**6.** $f(x) = \cos x$; $[a, b] = [-\pi/2, \pi/2]$

**7.** $f(x) = \sqrt{1 - x^2}$; $[a, b] = [0, 1]$

**8.** $f(x) = \sqrt{1 - x^2}$; $[a, b] = [-1, 1]$

**9.** $f(x) = e^x$; $[a, b] = [-1, 1]$

**10.** $f(x) = \ln x$; $[a, b] = [1, 2]$

**11.** $f(x) = \sin^{-1} x$; $[a, b] = [0, 1]$

**12.** $f(x) = \tan^{-1} x$; $[a, b] = [0, 1]$

**13–18** Graph each function over the specified interval. Then use simple area formulas from geometry to find the area function $A(x)$ that gives the area between the graph of the specified function $f$ and the interval $[a, x]$. Confirm that $A'(x) = f(x)$ in every case. ■

**13.** $f(x) = 3$; $[a, x] = [1, x]$

**14.** $f(x) = 5$; $[a, x] = [2, x]$

**15.** $f(x) = 2x + 2$; $[a, x] = [0, x]$

**16.** $f(x) = 3x - 3$; $[a, x] = [1, x]$

**17.** $f(x) = 2x + 2$; $[a, x] = [1, x]$

**18.** $f(x) = 3x - 3$; $[a, x] = [2, x]$

**19–22 True–False** Determine whether the statement is true or false. Explain your answer. ■

**19.** If $A(n)$ denotes the area of a regular $n$-sided polygon inscribed in a circle of radius 2, then $\lim_{n \to +\infty} A(n) = 2\pi$.

**20.** If the area under the curve $y = x^2$ over an interval is approximated by the total area of a collection of rectangles, the approximation will be too large.

**21.** If $A(x)$ is the area under the graph of a nonnegative continuous function $f$ over an interval $[a, x]$, then $A'(x) = f(x)$.

**22.** If $A(x)$ is the area under the graph of a nonnegative continuous function $f$ over an interval $[a, x]$, then $A(x)$ will be a continuous function.

**FOCUS ON CONCEPTS**

**23.** Explain how to use the formula for $A(x)$ found in the solution to Example 2 to determine the area between the graph of $y = x^2$ and the interval $[3, 6]$.

**24.** Repeat Exercise 23 for the interval $[-3, 9]$.

**25.** Let $A$ denote the area between the graph of $f(x) = \sqrt{x}$ and the interval $[0, 1]$, and let $B$ denote the area between the graph of $f(x) = x^2$ and the interval $[0, 1]$. Explain geometrically why $A + B = 1$.

**26.** Let $A$ denote the area between the graph of $f(x) = 1/x$ and the interval $[1, 2]$, and let $B$ denote the area between the graph of $f$ and the interval $\left[\frac{1}{2}, 1\right]$. Explain geometrically why $A = B$.

**27–28** The area $A(x)$ under the graph of $f$ and over the interval $[a, x]$ is given. Find the function $f$ and the value of $a$. ■

**27.** $A(x) = x^2 - 4$ **28.** $A(x) = x^2 - x$

**29. Writing** Compare and contrast the rectangle method and the antiderivative method.

**30. Writing** Suppose that $f$ is a nonnegative continuous function on an interval $[a, b]$ and that $g(x) = f(x) + C$, where $C$ is a positive constant. What will be the area of the region *between* the graphs of $f$ and $g$?

## ✔ QUICK CHECK ANSWERS 5.1

**1.** (a) $\frac{\pi}{2}$ (b) $1 + \frac{\sqrt{3}}{2}$ **2.** 2 **3.** 9 **4.** $A(x) = \frac{x^2}{2}$; $A'(x) = \frac{2x}{2} = x = f(x)$ **5.** $e^x + 1$

# 5.2 THE INDEFINITE INTEGRAL

*In the last section we saw how antidifferentiation could be used to find exact areas. In this section we will develop some fundamental results about antidifferentiation.*

## ANTIDERIVATIVES

**5.2.1 DEFINITION** A function $F$ is called an ***antiderivative*** of a function $f$ on a given open interval if $F'(x) = f(x)$ for all $x$ in the interval.

For example, the function $F(x) = \frac{1}{3}x^3$ is an antiderivative of $f(x) = x^2$ on the interval $(-\infty, +\infty)$ because for each $x$ in this interval

$$F'(x) = \frac{d}{dx}\left[\tfrac{1}{3}x^3\right] = x^2 = f(x)$$

However, $F(x) = \frac{1}{3}x^3$ is not the only antiderivative of $f$ on this interval. If we add any constant $C$ to $\frac{1}{3}x^3$, then the function $G(x) = \frac{1}{3}x^3 + C$ is also an antiderivative of $f$ on $(-\infty, +\infty)$, since

$$G'(x) = \frac{d}{dx}\left[\tfrac{1}{3}x^3 + C\right] = x^2 + 0 = f(x)$$

In general, once any single antiderivative is known, other antiderivatives can be obtained by adding constants to the known antiderivative. Thus,

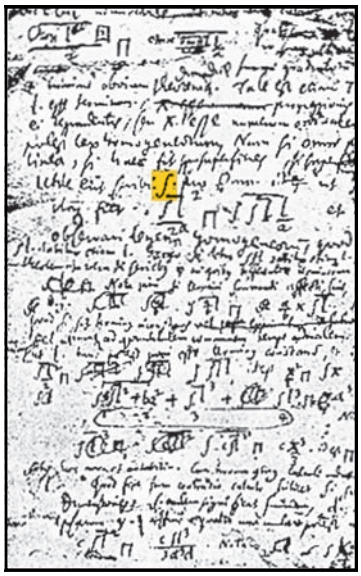
$$\tfrac{1}{3}x^3, \quad \tfrac{1}{3}x^3 + 2, \quad \tfrac{1}{3}x^3 - 5, \quad \tfrac{1}{3}x^3 + \sqrt{2}$$

are all antiderivatives of $f(x) = x^2$.

It is reasonable to ask if there are antiderivatives of a function $f$ that cannot be obtained by adding some constant to a known antiderivative $F$. The answer is *no*—once a single antiderivative of $f$ on an open interval is known, all other antiderivatives on that interval are obtainable by adding constants to the known antiderivative. This is so because Theorem 4.8.3 tells us that if two functions have the same derivative on an open interval, then the functions differ by a constant on the interval. The following theorem summarizes these observations.

**5.2.2 THEOREM** *If $F(x)$ is any antiderivative of $f(x)$ on an open interval, then for any constant $C$ the function $F(x) + C$ is also an antiderivative on that interval. Moreover, each antiderivative of $f(x)$ on the interval can be expressed in the form $F(x) + C$ by choosing the constant $C$ appropriately.*

## THE INDEFINITE INTEGRAL



Reproduced from C. I. Gerhardt's "Briefwechsel von G. W. Leibniz mit Mathematikern (1899)."

*Extract from the manuscript of Leibniz dated October 29, 1675 in which the integral sign first appeared (see yellow highlight).*

The process of finding antiderivatives is called ***antidifferentiation*** or ***integration***. Thus, if

$$\frac{d}{dx}[F(x)] = f(x) \tag{1}$$

then ***integrating*** (or ***antidifferentiating***) the function $f(x)$ produces an antiderivative of the form $F(x) + C$. To emphasize this process, Equation (1) is recast using ***integral notation***,

$$\int f(x)\,dx = F(x) + C \tag{2}$$

where $C$ is understood to represent an arbitrary constant. It is important to note that (1) and (2) are just different notations to express the same fact. For example,

$$\int x^2\,dx = \tfrac{1}{3}x^3 + C \quad \text{is equivalent to} \quad \frac{d}{dx}\left[\tfrac{1}{3}x^3\right] = x^2$$

Note that if we differentiate an antiderivative of $f(x)$, we obtain $f(x)$ back again. Thus,

$$\frac{d}{dx}\left[\int f(x)\,dx\right] = f(x) \tag{3}$$

The expression $\int f(x)\,dx$ is called an ***indefinite integral***. The adjective "indefinite" emphasizes that the result of antidifferentiation is a "generic" function, described only up to a constant term. The "elongated s" that appears on the left side of (2) is called an ***integral sign***,* the function $f(x)$ is called the ***integrand***, and the constant $C$ is called the ***constant of integration***. Equation (2) should be read as:

*The integral of $f(x)$ with respect to $x$ is equal to $F(x)$ plus a constant.*

The differential symbol, $dx$, in the differentiation and antidifferentiation operations

$$\frac{d}{dx}[\ ] \quad \text{and} \quad \int [\ ]\,dx$$

*This notation was devised by Leibniz. In his early papers Leibniz used the notation "omn." (an abbreviation for the Latin word "omnes") to denote integration. Then on October 29, 1675 he wrote, "It will be useful to write $\int$ for omn., thus $\int l$ for omn. $l$ . . . ." Two or three weeks later he refined the notation further and wrote $\int [\ ]\,dx$ rather than $\int$ alone. This notation is so useful and so powerful that its development by Leibniz must be regarded as a major milestone in the history of mathematics and science.

serves to identify the independent variable. If an independent variable other than $x$ is used, say $t$, then the notation must be adjusted appropriately. Thus,

$$\frac{d}{dt}[F(t)] = f(t) \quad \text{and} \quad \int f(t)\,dt = F(t) + C$$

are equivalent statements. Here are some examples of derivative formulas and their equivalent integration formulas:

| DERIVATIVE FORMULA | EQUIVALENT INTEGRATION FORMULA |
|---|---|
| $\frac{d}{dx}[x^3] = 3x^2$ | $\int 3x^2\,dx = x^3 + C$ |
| $\frac{d}{dx}[\sqrt{x}] = \frac{1}{2\sqrt{x}}$ | $\int \frac{1}{2\sqrt{x}}dx = \sqrt{x} + C$ |
| $\frac{d}{dt}[\tan t] = \sec^2 t$ | $\int \sec^2 t\,dt = \tan t + C$ |
| $\frac{d}{du}[u^{3/2}] = \frac{3}{2}u^{1/2}$ | $\int \frac{3}{2}u^{1/2}\,du = u^{3/2} + C$ |

For simplicity, the $dx$ is sometimes absorbed into the integrand. For example,

$$\int 1\,dx \quad \text{can be written as} \quad \int dx$$

$$\int \frac{1}{x^2}\,dx \quad \text{can be written as} \quad \int \frac{dx}{x^2}$$

## INTEGRATION FORMULAS

Integration is essentially educated guesswork—given the derivative $f$ of a function $F$, one tries to guess what the function $F$ is. However, many basic integration formulas can be obtained directly from their companion differentiation formulas. Some of the most important are given in Table 5.2.1.

**Table 5.2.1**
INTEGRATION FORMULAS

| DIFFERENTIATION FORMULA | INTEGRATION FORMULA | DIFFERENTIATION FORMULA | INTEGRATION FORMULA |
|---|---|---|---|
| 1. $\frac{d}{dx}[x] = 1$ | $\int dx = x + C$ | 8. $\frac{d}{dx}[-\csc x] = \csc x \cot x$ | $\int \csc x \cot x\,dx = -\csc x + C$ |
| 2. $\frac{d}{dx}\left[\frac{x^{r+1}}{r+1}\right] = x^r \quad (r \neq -1)$ | $\int x^r\,dx = \frac{x^{r+1}}{r+1} + C \quad (r \neq -1)$ | 9. $\frac{d}{dx}[e^x] = e^x$ | $\int e^x\,dx = e^x + C$ |
| 3. $\frac{d}{dx}[\sin x] = \cos x$ | $\int \cos x\,dx = \sin x + C$ | 10. $\frac{d}{dx}\left[\frac{b^x}{\ln b}\right] = b^x \quad (0 < b, b \neq 1)$ | $\int b^x\,dx = \frac{b^x}{\ln b} + C \quad (0 < b, b \neq 1)$ |
| 4. $\frac{d}{dx}[-\cos x] = \sin x$ | $\int \sin x\,dx = -\cos x + C$ | 11. $\frac{d}{dx}[\ln \lvert x\rvert] = \frac{1}{x}$ | $\int \frac{1}{x}dx = \ln \lvert x\rvert + C$ |
| 5. $\frac{d}{dx}[\tan x] = \sec^2 x$ | $\int \sec^2 x\,dx = \tan x + C$ | 12. $\frac{d}{dx}[\tan^{-1} x] = \frac{1}{1+x^2}$ | $\int \frac{1}{1+x^2}\,dx = \tan^{-1} x + C$ |
| 6. $\frac{d}{dx}[-\cot x] = \csc^2 x$ | $\int \csc^2 x\,dx = -\cot x + C$ | 13. $\frac{d}{dx}[\sin^{-1} x] = \frac{1}{\sqrt{1-x^2}}$ | $\int \frac{1}{\sqrt{1-x^2}}\,dx = \sin^{-1} x + C$ |
| 7. $\frac{d}{dx}[\sec x] = \sec x \tan x$ | $\int \sec x \tan x\,dx = \sec x + C$ | 14. $\frac{d}{dx}[\sec^{-1} \lvert x\rvert] = \frac{1}{x\sqrt{x^2-1}}$ | $\int \frac{1}{x\sqrt{x^2-1}}\,dx = \sec^{-1} \lvert x\rvert + C$ |

See Exercise 72 for a justification of Formula 14 in Table 5.2.1.

▶ **Example 1** The second integration formula in Table 5.2.1 will be easier to remember if you express it in words:

*To integrate a power of $x$ (other than $-1$), add 1 to the exponent and divide by the new exponent.*

Although Formula 2 in Table 5.2.1 is not applicable to integrating $x^{-1}$, this function can be integrated by rewriting the integral in Formula 11 as

$$\int \frac{1}{x}\,dx = \int x^{-1}\,dx = \ln|x| + C$$

Here are some examples:

$$\int x^2\,dx = \frac{x^3}{3} + C \qquad r = 2$$

$$\int x^3\,dx = \frac{x^4}{4} + C \qquad r = 3$$

$$\int \frac{1}{x^5}\,dx = \int x^{-5}\,dx = \frac{x^{-5+1}}{-5+1} + C = -\frac{1}{4x^4} + C \qquad r = -5$$

$$\int \sqrt{x}\,dx = \int x^{\frac{1}{2}}\,dx = \frac{x^{\frac{1}{2}+1}}{\frac{1}{2}+1} + C = \tfrac{2}{3}x^{\frac{3}{2}} + C = \tfrac{2}{3}(\sqrt{x})^3 + C \qquad r = \tfrac{1}{2}$$ ◀

## PROPERTIES OF THE INDEFINITE INTEGRAL

Our first properties of antiderivatives follow directly from the simple constant factor, sum, and difference rules for derivatives.

**5.2.3 THEOREM** *Suppose that $F(x)$ and $G(x)$ are antiderivatives of $f(x)$ and $g(x)$, respectively, and that $c$ is a constant. Then:*

(*a*) *A constant factor can be moved through an integral sign; that is,*

$$\int cf(x)\,dx = cF(x) + C$$

(*b*) *An antiderivative of a sum is the sum of the antiderivatives; that is,*

$$\int [f(x) + g(x)]\,dx = F(x) + G(x) + C$$

(*c*) *An antiderivative of a difference is the difference of the antiderivatives; that is,*

$$\int [f(x) - g(x)]\,dx = F(x) - G(x) + C$$

**PROOF** In general, to establish the validity of an equation of the form

$$\int h(x)\,dx = H(x) + C$$

one must show that

$$\frac{d}{dx}[H(x)] = h(x)$$

We are given that $F(x)$ and $G(x)$ are antiderivatives of $f(x)$ and $g(x)$, respectively, so we know that

$$\frac{d}{dx}[F(x)] = f(x) \quad \text{and} \quad \frac{d}{dx}[G(x)] = g(x)$$

Thus,

$$\frac{d}{dx}[cF(x)] = c\frac{d}{dx}[F(x)] = cf(x)$$

$$\frac{d}{dx}[F(x) + G(x)] = \frac{d}{dx}[F(x)] + \frac{d}{dx}[G(x)] = f(x) + g(x)$$

$$\frac{d}{dx}[F(x) - G(x)] = \frac{d}{dx}[F(x)] - \frac{d}{dx}[G(x)] = f(x) - g(x)$$

which proves the three statements of the theorem. ■

The statements in Theorem 5.2.3 can be summarized by the following formulas:

$$\int cf(x)\,dx = c\int f(x)\,dx \tag{4}$$

$$\int [f(x) + g(x)]\,dx = \int f(x)\,dx + \int g(x)\,dx \tag{5}$$

$$\int [f(x) - g(x)]\,dx = \int f(x)\,dx - \int g(x)\,dx \tag{6}$$

However, these equations must be applied carefully to avoid errors and unnecessary complexities arising from the constants of integration. For example, if you use (4) to integrate $2x$ by writing

$$\int 2x\,dx = 2\int x\,dx = 2\left(\frac{x^2}{2} + C\right) = x^2 + 2C$$

then you will have an unnecessarily complicated form of the arbitrary constant. This kind of problem can be avoided by inserting the constant of integration in the final result rather than in intermediate calculations. Exercises 65 and 66 explore how careless application of these formulas can lead to errors.

▶ **Example 2** Evaluate

$$\text{(a)} \int 4\cos x\,dx \qquad \text{(b)} \int (x + x^2)\,dx$$

***Solution (a).*** Since $F(x) = \sin x$ is an antiderivative for $f(x) = \cos x$ (Table 5.2.1), we obtain

$$\int 4\cos x\,dx = 4\int \cos x\,dx = 4\sin x + C$$

(4)

***Solution (b).*** From Table 5.2.1 we obtain

$$\int (x + x^2)\,dx = \int x\,dx + \int x^2\,dx = \frac{x^2}{2} + \frac{x^3}{3} + C \quad ◀$$

(5)

Parts $(b)$ and $(c)$ of Theorem 5.2.3 can be extended to more than two functions, which in combination with part $(a)$ results in the following general formula:

$$\int [c_1 f_1(x) + c_2 f_2(x) + \cdots + c_n f_n(x)]\,dx = c_1\int f_1(x)\,dx + c_2\int f_2(x)\,dx + \cdots + c_n\int f_n(x)\,dx \tag{7}$$

**▶ Example 3**

$$\int (3x^6 - 2x^2 + 7x + 1)\,dx = 3\int x^6\,dx - 2\int x^2\,dx + 7\int x\,dx + \int 1\,dx$$
$$= \frac{3x^7}{7} - \frac{2x^3}{3} + \frac{7x^2}{2} + x + C \quad \blacktriangleleft$$

Sometimes it is useful to rewrite an integrand in a different form before performing the integration. This is illustrated in the following example.

**▶ Example 4** Evaluate

$$\text{(a)} \int \frac{\cos x}{\sin^2 x}\,dx \qquad \text{(b)} \int \frac{t^2 - 2t^4}{t^4}\,dt \qquad \text{(c)} \int \frac{x^2}{x^2 + 1}\,dx$$

***Solution (a).***

$$\int \frac{\cos x}{\sin^2 x}\,dx = \int \frac{1}{\sin x}\frac{\cos x}{\sin x}\,dx = \int \csc x \cot x\,dx = -\csc x + C$$

Formula 8 in Table 5.2.1

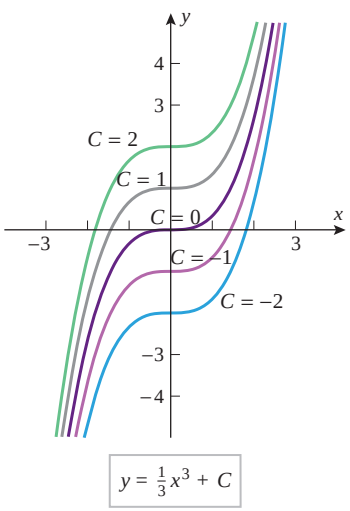
***Solution (b).***

$$\int \frac{t^2 - 2t^4}{t^4}\,dt = \int \left(\frac{1}{t^2} - 2\right) dt = \int (t^{-2} - 2)\,dt$$
$$= \frac{t^{-1}}{-1} - 2t + C = -\frac{1}{t} - 2t + C$$

Perform the integration in part (c) by first performing a long division on the integrand.

***Solution (c).*** By adding and subtracting 1 from the numerator of the integrand, we can rewrite the integral in a form in which Formulas 1 and 12 of Table 5.2.1 can be applied:

$$\int \frac{x^2}{x^2 + 1}\,dx = \int \left(\frac{x^2 + 1}{x^2 + 1} - \frac{1}{x^2 + 1}\right) dx$$
$$= \int \left(1 - \frac{1}{x^2 + 1}\right) dx = x - \tan^{-1} x + C \quad \blacktriangleleft$$



▲ Figure 5.2.1

## INTEGRAL CURVES

Graphs of antiderivatives of a function $f$ are called ***integral curves*** of $f$. We know from Theorem 5.2.2 that if $y = F(x)$ is any integral curve of $f(x)$, then all other integral curves are vertical translations of this curve, since they have equations of the form $y = F(x) + C$. For example, $y = \frac{1}{3}x^3$ is one integral curve for $f(x) = x^2$, so all the other integral curves have equations of the form $y = \frac{1}{3}x^3 + C$; conversely, the graph of any equation of this form is an integral curve (Figure 5.2.1).

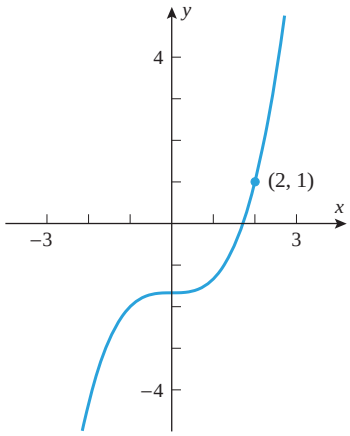
In many problems one is interested in finding a function whose derivative satisfies specified conditions. The following example illustrates a geometric problem of this type.

**▶ Example 5** Suppose that a curve $y = f(x)$ in the $xy$-plane has the property that at each point $(x, y)$ on the curve, the tangent line has slope $x^2$. Find an equation for the curve given that it passes through the point $(2, 1)$.

***Solution.*** Since the slope of the line tangent to $y = f(x)$ is $dy/dx$, we have $dy/dx = x^2$, and

$$y = \int x^2\,dx = \tfrac{1}{3}x^3 + C$$

In Example 5, the requirement that the graph of $f$ pass through the point $(2, 1)$ selects the single integral curve $y = \frac{1}{3}x^3 - \frac{5}{3}$ from the family of curves $y = \frac{1}{3}x^3 + C$ (Figure 5.2.2).



▲ Figure 5.2.2

Since the curve passes through $(2, 1)$, a specific value for $C$ can be found by using the fact that $y = 1$ if $x = 2$. Substituting these values in the above equation yields

$$1 = \tfrac{1}{3}(2^3) + C \quad \text{or} \quad C = -\tfrac{5}{3}$$

so an equation of the curve is

$$y = \tfrac{1}{3}x^3 - \tfrac{5}{3}$$

(Figure 5.2.2). ◄

## INTEGRATION FROM THE VIEWPOINT OF DIFFERENTIAL EQUATIONS

We will now consider another way of looking at integration that will be useful in our later work. Suppose that $f(x)$ is a known function and we are interested in finding a function $F(x)$ such that $y = F(x)$ satisfies the equation

$$\frac{dy}{dx} = f(x) \tag{8}$$

The solutions of this equation are the antiderivatives of $f(x)$, and we know that these can be obtained by integrating $f(x)$. For example, the solutions of the equation

$$\frac{dy}{dx} = x^2 \tag{9}$$

are

$$y = \int x^2\,dx = \frac{x^3}{3} + C$$

Equation (8) is called a ***differential equation*** because it involves a derivative of an unknown function. Differential equations are different from the kinds of equations we have encountered so far in that the unknown is a *function* and not a *number* as in an equation such as $x^2 + 5x - 6 = 0$.

Sometimes we will not be interested in finding all of the solutions of (8), but rather we will want only the solution whose graph passes through a specified point $(x_0, y_0)$. For example, in Example 5 we solved (9) for the integral curve that passed through the point $(2, 1)$.

For simplicity, it is common in the study of differential equations to denote a solution of $dy/dx = f(x)$ as $y(x)$ rather than $F(x)$, as earlier. With this notation, the problem of finding a function $y(x)$ whose derivative is $f(x)$ and whose graph passes through the point $(x_0, y_0)$ is expressed as

$$\frac{dy}{dx} = f(x), \quad y(x_0) = y_0 \tag{10}$$

This is called an ***initial-value problem***, and the requirement that $y(x_0) = y_0$ is called the ***initial condition*** for the problem.

► **Example 6** Solve the initial-value problem

$$\frac{dy}{dx} = \cos x, \quad y(0) = 1$$

***Solution.*** The solution of the differential equation is

$$y = \int \cos x\,dx = \sin x + C \tag{11}$$

The initial condition $y(0) = 1$ implies that $y = 1$ if $x = 0$; substituting these values in (11) yields

$$1 = \sin(0) + C \quad \text{or} \quad C = 1$$

Thus, the solution of the initial-value problem is $y = \sin x + 1$. ◄

## SLOPE FIELDS

If we interpret $dy/dx$ as the slope of a tangent line, then at a point $(x, y)$ on an integral curve of the equation $dy/dx = f(x)$, the slope of the tangent line is $f(x)$. What is interesting about this is that the slopes of the tangent lines to the integral curves can be obtained without actually solving the differential equation. For example, if

$$\frac{dy}{dx} = \sqrt{x^2 + 1}$$

then we know without solving the equation that at the point where $x = 1$ the tangent line to an integral curve has slope $\sqrt{1^2 + 1} = \sqrt{2}$; and more generally, at a point where $x = a$, the tangent line to an integral curve has slope $\sqrt{a^2 + 1}$.

A geometric description of the integral curves of a differential equation $dy/dx = f(x)$ can be obtained by choosing a rectangular grid of points in the $xy$-plane, calculating the slopes of the tangent lines to the integral curves at the gridpoints, and drawing small portions of the tangent lines through those points. The resulting picture, which is called a ***slope field*** or ***direction field*** for the equation, shows the "direction" of the integral curves at the gridpoints. With sufficiently many gridpoints it is often possible to visualize the integral curves themselves; for example, Figure 5.2.3*a* shows a slope field for the differential equation $dy/dx = x^2$, and Figure 5.2.3*b* shows that same field with the integral curves imposed on it—the more gridpoints that are used, the more completely the slope field reveals the shape of the integral curves. However, the amount of computation can be considerable, so computers are usually used when slope fields with many gridpoints are needed.

Slope fields will be studied in more detail later in the text.

## ✔ QUICK CHECK EXERCISES 5.2 (See page 332 for answers.)

**1.** A function $F$ is an antiderivative of a function $f$ on an interval if _____ for all $x$ in the interval.

**2.** Write an equivalent integration formula for each given derivative formula.

(a) $\dfrac{d}{dx}[\sqrt{x}] = \dfrac{1}{2\sqrt{x}}$ (b) $\dfrac{d}{dx}[e^{4x}] = 4e^{4x}$

**3.** Evaluate the integrals.

(a) $\displaystyle\int [x^3 + x + 5]\,dx$ (b) $\displaystyle\int [\sec^2 x - \csc x \cot x]\,dx$

**4.** The graph of $y = x^2 + x$ is an integral curve for the function $f(x) =$ _____. If $G$ is a function whose graph is also an integral curve for $f$, and if $G(1) = 5$, then $G(x) =$ _____.

**5.** A slope field for the differential equation

$$\frac{dy}{dx} = \frac{2x}{x^2 - 4}$$

has a line segment with slope _____ through the point $(0, 5)$ and has a line segment with slope _____ through the point $(-4, 1)$.

## EXERCISE SET 5.2

Graphing Utility C CAS

1. In each part, confirm that the formula is correct, and state a corresponding integration formula.
   (a) $\dfrac{d}{dx}[\sqrt{1+x^2}\,] = \dfrac{x}{\sqrt{1+x^2}}$
   (b) $\dfrac{d}{dx}[xe^x] = (x+1)e^x$
2. In each part, confirm that the stated formula is correct by differentiating.
   (a) $\displaystyle\int x\sin x\,dx = \sin x - x\cos x + C$
   (b) $\displaystyle\int \frac{dx}{(1-x^2)^{3/2}} = \frac{x}{\sqrt{1-x^2}} + C$

**FOCUS ON CONCEPTS**

3. What is a *constant of integration*? Why does an answer to an integration problem involve a constant of integration?
4. What is an *integral curve* of a function $f$? How are two integral curves of a function $f$ related?

**5–8** Find the derivative and state a corresponding integration formula. ■

5. $\dfrac{d}{dx}[\sqrt{x^3+5}\,]$
6. $\dfrac{d}{dx}\left[\dfrac{x}{x^2+3}\right]$
7. $\dfrac{d}{dx}[\sin(2\sqrt{x})]$
8. $\dfrac{d}{dx}[\sin x - x\cos x]$

**9–10** Evaluate the integral by rewriting the integrand appropriately, if required, and applying the power rule (Formula 2 in Table 5.2.1). ■

9. (a) $\displaystyle\int x^8\,dx$ (b) $\displaystyle\int x^{5/7}\,dx$ (c) $\displaystyle\int x^3\sqrt{x}\,dx$
10. (a) $\displaystyle\int \sqrt[3]{x^2}\,dx$ (b) $\displaystyle\int \frac{1}{x^6}\,dx$ (c) $\displaystyle\int x^{-7/8}\,dx$

**11–14** Evaluate each integral by applying Theorem 5.2.3 and Formula 2 in Table 5.2.1 appropriately. ■

11. $\displaystyle\int\left[5x + \frac{2}{3x^5}\right]dx$
12. $\displaystyle\int\left[x^{-1/2} - 3x^{7/5} + \tfrac{1}{9}\right]dx$
13. $\displaystyle\int[x^{-3} - 3x^{1/4} + 8x^2]\,dx$
14. $\displaystyle\int\left[\frac{10}{y^{3/4}} - \sqrt[3]{y} + \frac{4}{\sqrt{y}}\right]dy$

**15–34** Evaluate the integral and check your answer by differentiating. ■

15. $\displaystyle\int x(1+x^3)\,dx$
16. $\displaystyle\int (2+y^2)^2\,dy$
17. $\displaystyle\int x^{1/3}(2-x)^2\,dx$
18. $\displaystyle\int (1+x^2)(2-x)\,dx$
19. $\displaystyle\int \frac{x^5+2x^2-1}{x^4}\,dx$
20. $\displaystyle\int \frac{1-2t^3}{t^3}\,dt$
21. $\displaystyle\int\left[\frac{2}{x} + 3e^x\right]dx$
22. $\displaystyle\int\left[\frac{1}{2t} - \sqrt{2}e^t\right]dt$
23. $\displaystyle\int[3\sin x - 2\sec^2 x]\,dx$
24. $\displaystyle\int[\csc^2 t - \sec t\tan t]\,dt$
25. $\displaystyle\int \sec x(\sec x + \tan x)\,dx$
26. $\displaystyle\int \csc x(\sin x + \cot x)\,dx$
27. $\displaystyle\int \frac{\sec\theta}{\cos\theta}\,d\theta$
28. $\displaystyle\int \frac{dy}{\csc y}$
29. $\displaystyle\int \frac{\sin x}{\cos^2 x}\,dx$
30. $\displaystyle\int\left[\phi + \frac{2}{\sin^2\phi}\right]d\phi$
31. $\displaystyle\int[1+\sin^2\theta\csc\theta]\,d\theta$
32. $\displaystyle\int \frac{\sec x + \cos x}{2\cos x}\,dx$
33. $\displaystyle\int\left[\frac{1}{2\sqrt{1-x^2}} - \frac{3}{1+x^2}\right]dx$
34. $\displaystyle\int\left[\frac{4}{x\sqrt{x^2-1}} + \frac{1+x+x^3}{1+x^2}\right]dx$
35. Evaluate the integral
$$\int \frac{1}{1+\sin x}\,dx$$
by multiplying the numerator and denominator by an appropriate expression.
36. Use the double-angle formula $\cos 2x = 2\cos^2 x - 1$ to evaluate the integral
$$\int \frac{1}{1+\cos 2x}\,dx$$

**37–40 True–False** Determine whether the statement is true or false. Explain your answer. ■

37. If $F(x)$ is an antiderivative of $f(x)$, then
$$\int f(x)\,dx = F(x) + C$$
38. If $C$ denotes a constant of integration, the two formulas
$$\int \cos x\,dx = \sin x + C$$
$$\int \cos x\,dx = (\sin x + \pi) + C$$
are both correct equations.
39. The function $f(x) = e^{-x} + 1$ is a solution to the initial-value problem
$$\frac{dy}{dx} = -\frac{1}{e^x}, \quad y(0) = 1$$
40. Every integral curve of the slope field
$$\frac{dy}{dx} = \frac{1}{\sqrt{x^2+1}}$$
is the graph of an increasing function of $x$.

**41.** Use a graphing utility to generate some representative integral curves of the function $f(x) = 5x^4 - \sec^2 x$ over the interval $(-\pi/2, \pi/2)$.

**42.** Use a graphing utility to generate some representative integral curves of the function $f(x) = (x-1)/x$ over the interval $(0, 5)$.

**43–46** Solve the initial-value problems.

**43.** (a) $\dfrac{dy}{dx} = \sqrt[3]{x},\ y(1) = 2$

(b) $\dfrac{dy}{dt} = \sin t + 1,\ y\left(\dfrac{\pi}{3}\right) = \dfrac{1}{2}$

(c) $\dfrac{dy}{dx} = \dfrac{x+1}{\sqrt{x}},\ y(1) = 0$

**44.** (a) $\dfrac{dy}{dx} = \dfrac{1}{(2x)^3},\ y(1) = 0$

(b) $\dfrac{dy}{dt} = \sec^2 t - \sin t,\ y\left(\dfrac{\pi}{4}\right) = 1$

(c) $\dfrac{dy}{dx} = x^2\sqrt{x^3},\ y(0) = 0$

**45.** (a) $\dfrac{dy}{dx} = 4e^x,\ y(0) = 1$ (b) $\dfrac{dy}{dt} = \dfrac{1}{t},\ y(-1) = 5$

**46.** (a) $\dfrac{dy}{dt} = \dfrac{3}{\sqrt{1-t^2}},\ y\left(\dfrac{\sqrt{3}}{2}\right) = 0$

(b) $\dfrac{dy}{dx} = \dfrac{x^2-1}{x^2+1},\ y(1) = \dfrac{\pi}{2}$

**47–50** A particle moves along an $s$-axis with position function $s = s(t)$ and velocity function $v(t) = s'(t)$. Use the given information to find $s(t)$.

**47.** $v(t) = 32t;\ \ s(0) = 20$ **48.** $v(t) = \cos t;\ \ s(0) = 2$

**49.** $v(t) = 3\sqrt{t};\ \ s(4) = 1$ **50.** $v(t) = 3e^t;\ \ s(1) = 0$

**51.** Find the general form of a function whose second derivative is $\sqrt{x}$. [*Hint:* Solve the equation $f''(x) = \sqrt{x}$ for $f(x)$ by integrating both sides twice.]

**52.** Find a function $f$ such that $f''(x) = x + \cos x$ and such that $f(0) = 1$ and $f'(0) = 2$. [*Hint:* Integrate both sides of the equation twice.]

**53–57** Find an equation of the curve that satisfies the given conditions.

**53.** At each point $(x, y)$ on the curve the slope is $2x + 1$; the curve passes through the point $(-3, 0)$.

**54.** At each point $(x, y)$ on the curve the slope is $(x+1)^2$; the curve passes through the point $(-2, 8)$.

**55.** At each point $(x, y)$ on the curve the slope is $-\sin x$; the curve passes through the point $(0, 2)$.

**56.** At each point $(x, y)$ on the curve the slope equals the square of the distance between the point and the $y$-axis; the point $(-1, 2)$ is on the curve.

**57.** At each point $(x, y)$ on the curve, $y$ satisfies the condition $d^2y/dx^2 = 6x$; the line $y = 5 - 3x$ is tangent to the curve at the point where $x = 1$.

**58.** In each part, use a CAS to solve the initial-value problem.

(a) $\dfrac{dy}{dx} = x^2 \cos 3x,\ \ y(\pi/2) = -1$

(b) $\dfrac{dy}{dx} = \dfrac{x^3}{(4+x^2)^{3/2}},\ \ y(0) = -2$

**59.** (a) Use a graphing utility to generate a slope field for the differential equation $dy/dx = x$ in the region $-5 \le x \le 5$ and $-5 \le y \le 5$.

(b) Graph some representative integral curves of the function $f(x) = x$.

(c) Find an equation for the integral curve that passes through the point $(2, 1)$.

**60.** (a) Use a graphing utility to generate a slope field for the differential equation $dy/dx = e^x/2$ in the region $-1 \le x \le 4$ and $-1 \le y \le 4$.

(b) Graph some representative integral curves of the function $f(x) = e^x/2$.

(c) Find an equation for the integral curve that passes through the point $(0, 1)$.

**61–64** The given slope field figure corresponds to one of the differential equations below. Identify the differential equation that matches the figure, and sketch solution curves through the highlighted points.

(a) $\dfrac{dy}{dx} = 2$ (b) $\dfrac{dy}{dx} = -x$

(c) $\dfrac{dy}{dx} = x^2 - 4$ (d) $\dfrac{dy}{dx} = e^{x/3}$

# 5.3 INTEGRATION BY SUBSTITUTION

*In this section we will study a technique, called* ***substitution****, that can often be used to transform complicated integration problems into simpler ones.*

## ■ *u*-SUBSTITUTION

The method of substitution can be motivated by examining the chain rule from the viewpoint of antidifferentiation. For this purpose, suppose that $F$ is an antiderivative of $f$ and that $g$ is a differentiable function. The chain rule implies that the derivative of $F(g(x))$ can be expressed as

$$\frac{d}{dx}[F(g(x))] = F'(g(x))g'(x)$$

which we can write in integral form as

$$\int F'(g(x))g'(x)\,dx = F(g(x)) + C \tag{1}$$

or since $F$ is an antiderivative of $f$,

$$\int f(g(x))g'(x)\,dx = F(g(x)) + C \tag{2}$$

For our purposes it will be useful to let $u = g(x)$ and to write $du/dx = g'(x)$ in the differential form $du = g'(x)\,dx$. With this notation (2) can be expressed as

$$\int f(u)\,du = F(u) + C \tag{3}$$

The process of evaluating an integral of form (2) by converting it into form (3) with the substitution

$$u = g(x) \quad \text{and} \quad du = g'(x)\,dx$$

is called the ***method of u-substitution***. Here our emphasis is *not* on the interpretation of the expression $du = g'(x)\,dx$. Rather, the differential notation serves primarily as a useful "bookkeeping" device for the method of $u$-substitution. The following example illustrates how the method works.

**▶ Example 1** Evaluate $\int (x^2 + 1)^{50} \cdot 2x\,dx$.

***Solution.*** If we let $u = x^2 + 1$, then $du/dx = 2x$, which implies that $du = 2x\,dx$. Thus, the given integral can be written as

$$\int (x^2 + 1)^{50} \cdot 2x\,dx = \int u^{50}\,du = \frac{u^{51}}{51} + C = \frac{(x^2 + 1)^{51}}{51} + C \quad \blacktriangleleft$$

It is important to realize that in the method of $u$-substitution you have control over the choice of $u$, but once you make that choice you have no control over the resulting expression for $du$. Thus, in the last example we *chose* $u = x^2 + 1$ but $du = 2x\,dx$ was *computed*. Fortunately, our choice of $u$, combined with the computed $du$, worked out perfectly to produce an integral involving $u$ that was easy to evaluate. However, in general, the method of $u$-substitution will fail if the chosen $u$ and the computed $du$ cannot be used to produce an integrand in which no expressions involving $x$ remain, or if you cannot evaluate the resulting integral. Thus, for example, the substitution $u = x^2$, $du = 2x\,dx$ will not work for the integral

$$\int 2x \sin x^4\,dx$$

because this substitution results in the integral

$$\int \sin u^2\,du$$

which still cannot be evaluated in terms of familiar functions.

In general, there are no hard and fast rules for choosing $u$, and in some problems no choice of $u$ will work. In such cases other methods need to be used, some of which will be discussed later. Making appropriate choices for $u$ will come with experience, but you may find the following guidelines, combined with a mastery of the basic integrals in Table 5.2.1, helpful.

***Guidelines for u-Substitution***

**Step 1.** Look for some composition $f(g(x))$ within the integrand for which the substitution

$$u = g(x), \quad du = g'(x)\,dx$$

produces an integral that is expressed entirely in terms of $u$ and its differential $du$. This may or may not be possible.

**Step 2.** If you are successful in Step 1, then try to evaluate the resulting integral in terms of $u$. Again, this may or may not be possible.

**Step 3.** If you are successful in Step 2, then replace $u$ by $g(x)$ to express your final answer in terms of $x$.

## EASY TO RECOGNIZE SUBSTITUTIONS

The easiest substitutions occur when the integrand is the derivative of a known function, except for a constant added to or subtracted from the independent variable.

**▶ Example 2**

$$\int \sin(x+9)\,dx = \int \sin u\,du = -\cos u + C = -\cos(x+9) + C$$

$u = x + 9$, $du = 1 \cdot dx = dx$

$$\int (x-8)^{23}\,dx = \int u^{23}\,du = \frac{u^{24}}{24} + C = \frac{(x-8)^{24}}{24} + C \quad \blacktriangleleft$$

$u = x - 8$, $du = 1 \cdot dx = dx$

Another easy $u$-substitution occurs when the integrand is the derivative of a known function, except for a constant that multiplies or divides the independent variable. The following example illustrates two ways to evaluate such integrals.

**▶ Example 3** Evaluate $\int \cos 5x\,dx$.

***Solution.***

$$\int \cos 5x\,dx = \int (\cos u) \cdot \frac{1}{5}\,du = \frac{1}{5}\int \cos u\,du = \frac{1}{5}\sin u + C = \frac{1}{5}\sin 5x + C$$

$u = 5x$, $du = 5\,dx$ or $dx = \frac{1}{5}\,du$

***Alternative Solution.*** There is a variation of the preceding method that some people prefer. The substitution $u = 5x$ requires $du = 5\,dx$. If there were a factor of 5 in the integrand, then we could group the 5 and $dx$ together to form the $du$ required by the substitution. Since there is no factor of 5, we will insert one and compensate by putting a factor of $\frac{1}{5}$ in front of the integral. The computations are as follows:

$$\int \cos 5x\,dx = \frac{1}{5}\int \cos 5x \cdot 5\,dx = \frac{1}{5}\int \cos u\,du = \frac{1}{5}\sin u + C = \frac{1}{5}\sin 5x + C \quad \blacktriangleleft$$

$u = 5x$, $du = 5\,dx$

More generally, if the integrand is a composition of the form $f(ax+b)$, where $f(x)$ is an easy to integrate function, then the substitution $u = ax+b$, $du = a\,dx$ will work.

**▶ Example 4**

$$\int \frac{dx}{\left(\frac{1}{3}x-8\right)^5} = \int \frac{3\,du}{u^5} = 3\int u^{-5}\,du = -\frac{3}{4}u^{-4}+C = -\frac{3}{4}\left(\frac{1}{3}x-8\right)^{-4}+C \quad \blacktriangleleft$$

$u = \frac{1}{3}x - 8$, $du = \frac{1}{3}\,dx$ or $dx = 3\,du$

**▶ Example 5** Evaluate $\displaystyle\int \frac{dx}{1+3x^2}$.

***Solution.*** Substituting

$$u = \sqrt{3}x, \quad du = \sqrt{3}\,dx$$

yields

$$\int \frac{dx}{1+3x^2} = \frac{1}{\sqrt{3}}\int \frac{du}{1+u^2} = \frac{1}{\sqrt{3}}\tan^{-1}u + C = \frac{1}{\sqrt{3}}\tan^{-1}(\sqrt{3}x) + C \quad \blacktriangleleft$$

With the help of Theorem 5.2.3, a complicated integral can sometimes be computed by expressing it as a sum of simpler integrals.

**▶ Example 6**

$$\begin{aligned}\int \left(\frac{1}{x}+\sec^2\pi x\right)dx &= \int \frac{dx}{x} + \int \sec^2\pi x\,dx \\ &= \ln|x| + \int \sec^2\pi x\,dx \\ &= \ln|x| + \frac{1}{\pi}\int \sec^2 u\,du \\ &= \ln|x| + \frac{1}{\pi}\tan u + C = \ln|x| + \frac{1}{\pi}\tan\pi x + C \quad \blacktriangleleft\end{aligned}$$

$u = \pi x$, $du = \pi\,dx$ or $dx = \frac{1}{\pi}\,du$

The next four examples illustrate a substitution $u = g(x)$ where $g(x)$ is a nonlinear function.

**▶ Example 7** Evaluate $\displaystyle\int \sin^2 x\cos x\,dx$.

***Solution.*** If we let $u = \sin x$, then

$$\frac{du}{dx} = \cos x, \quad \text{so} \quad du = \cos x\,dx$$

Thus,

$$\int \sin^2 x\cos x\,dx = \int u^2\,du = \frac{u^3}{3}+C = \frac{\sin^3 x}{3}+C \quad \blacktriangleleft$$

▶ **Example 8** Evaluate $\displaystyle\int \frac{e^{\sqrt{x}}}{\sqrt{x}}\,dx$.

***Solution.*** If we let $u = \sqrt{x}$, then

$$\frac{du}{dx} = \frac{1}{2\sqrt{x}}, \quad \text{so} \quad du = \frac{1}{2\sqrt{x}}\,dx \quad \text{or} \quad 2\,du = \frac{1}{\sqrt{x}}\,dx$$

Thus,

$$\int \frac{e^{\sqrt{x}}}{\sqrt{x}}\,dx = \int 2e^u\,du = 2\int e^u\,du = 2e^u + C = 2e^{\sqrt{x}} + C \quad \blacktriangleleft$$

▶ **Example 9** Evaluate $\displaystyle\int t^4\sqrt[3]{3-5t^5}\,dt$.

***Solution.***

$$\int t^4\sqrt[3]{3-5t^5}\,dt = -\frac{1}{25}\int \sqrt[3]{u}\,du = -\frac{1}{25}\int u^{1/3}\,du$$

$u = 3 - 5t^5$
$du = -25t^4\,dt$ or $-\frac{1}{25}\,du = t^4\,dt$

$$= -\frac{1}{25}\frac{u^{4/3}}{4/3} + C = -\frac{3}{100}\left(3-5t^5\right)^{4/3} + C \quad \blacktriangleleft$$

▶ **Example 10** Evaluate $\displaystyle\int \frac{e^x}{\sqrt{1-e^{2x}}}\,dx$.

***Solution.*** Substituting

$$u = e^x, \quad du = e^x\,dx$$

yields

$$\int \frac{e^x}{\sqrt{1-e^{2x}}}\,dx = \int \frac{du}{\sqrt{1-u^2}} = \sin^{-1}u + C = \sin^{-1}(e^x) + C \quad \blacktriangleleft$$

## LESS APPARENT SUBSTITUTIONS

The method of substitution is relatively straightforward, provided the integrand contains an easily recognized composition $f(g(x))$ and the remainder of the integrand is a constant multiple of $g'(x)$. If this is not the case, the method may still apply but may require more computation.

▶ **Example 11** Evaluate $\displaystyle\int x^2\sqrt{x-1}\,dx$.

***Solution.*** The composition $\sqrt{x-1}$ suggests the substitution

$$u = x - 1 \quad \text{so that} \quad du = dx \tag{4}$$

From the first equality in (4)

$$x^2 = (u+1)^2 = u^2 + 2u + 1$$

so that

$$\int x^2\sqrt{x-1}\,dx = \int (u^2+2u+1)\sqrt{u}\,du = \int (u^{5/2} + 2u^{3/2} + u^{1/2})\,du$$

$$= \tfrac{2}{7}u^{7/2} + \tfrac{4}{5}u^{5/2} + \tfrac{2}{3}u^{3/2} + C$$

$$= \tfrac{2}{7}(x-1)^{7/2} + \tfrac{4}{5}(x-1)^{5/2} + \tfrac{2}{3}(x-1)^{3/2} + C \quad \blacktriangleleft$$

**▶ Example 12** Evaluate $\int \cos^3 x\, dx$.

***Solution.*** The only compositions in the integrand that suggest themselves are

$$\cos^3 x = (\cos x)^3 \quad \text{and} \quad \cos^2 x = (\cos x)^2$$

However, neither the substitution $u = \cos x$ nor the substitution $u = \cos^2 x$ work (verify). In this case, an appropriate substitution is not suggested by the composition contained in the integrand. On the other hand, note from Equation (2) that the derivative $g'(x)$ appears as a factor in the integrand. This suggests that we write

$$\int \cos^3 x\, dx = \int \cos^2 x \cos x\, dx$$

and solve the equation $du = \cos x\, dx$ for $u = \sin x$. Since $\sin^2 x + \cos^2 x = 1$, we then have

$$\int \cos^3 x\, dx = \int \cos^2 x \cos x\, dx = \int (1 - \sin^2 x)\cos x\, dx = \int (1 - u^2)\, du$$

$$= u - \frac{u^3}{3} + C = \sin x - \frac{1}{3}\sin^3 x + C \quad \blacktriangleleft$$

**▶ Example 13** Evaluate $\int \frac{dx}{a^2 + x^2}\, dx$, where $a \neq 0$ is a constant.

***Solution.*** Some simple algebra and an appropriate $u$-substitution will allow us to use Formula 12 in Table 5.2.1.

$$\int \frac{dx}{a^2 + x^2} = \int \frac{a(dx/a)}{a^2(1 + (x/a)^2)} = \frac{1}{a}\int \frac{dx/a}{1 + (x/a)^2} \qquad \begin{matrix} u = x/a \\ du = dx/a \end{matrix}$$

$$= \frac{1}{a}\int \frac{du}{1 + u^2} = \frac{1}{a}\tan^{-1} u + C = \frac{1}{a}\tan^{-1}\frac{x}{a} + C \quad \blacktriangleleft$$

The method of Example 13 leads to the following generalizations of Formulas 12, 13, and 14 in Table 5.2.1 for $a > 0$:

$$\int \frac{du}{a^2 + u^2} = \frac{1}{a}\tan^{-1}\frac{u}{a} + C \tag{5}$$

$$\int \frac{du}{\sqrt{a^2 - u^2}} = \sin^{-1}\frac{u}{a} + C \tag{6}$$

$$\int \frac{du}{u\sqrt{u^2 - a^2}} = \frac{1}{a}\sec^{-1}\left|\frac{u}{a}\right| + C \tag{7}$$

**▶ Example 14** Evaluate $\int \frac{dx}{\sqrt{2 - x^2}}$.

***Solution.*** Applying (6) with $u = x$ and $a = \sqrt{2}$ yields

$$\int \frac{dx}{\sqrt{2 - x^2}} = \sin^{-1}\frac{x}{\sqrt{2}} + C \quad \blacktriangleleft$$

**TECHNOLOGY MASTERY**

If you have a CAS, use it to calculate the integrals in the examples in this section. If your CAS produces an answer that is different from the one in the text, then confirm algebraically that the two answers agree. Also, explore the effect of using the CAS to simplify the expressions it produces for the integrals.

## INTEGRATION USING COMPUTER ALGEBRA SYSTEMS

The advent of computer algebra systems has made it possible to evaluate many kinds of integrals that would be laborious to evaluate by hand. For example, a handheld calculator evaluated the integral

$$\int \frac{5x^2}{(1+x)^{1/3}}\,dx = \frac{3(x+1)^{2/3}(5x^2-6x+9)}{8} + C$$

in about a second. The computer algebra system *Mathematica*, running on a personal computer, required even less time to evaluate this same integral. However, just as one would not want to rely on a calculator to compute $2+2$, so one would not want to use a CAS to integrate a simple function such as $f(x) = x^2$. Thus, even if you have a CAS, you will want to develop a reasonable level of competence in evaluating basic integrals. Moreover, the mathematical techniques that we will introduce for evaluating basic integrals are precisely the techniques that computer algebra systems use to evaluate more complicated integrals.

## ✔ QUICK CHECK EXERCISES 5.3 (See page 340 for answers.)

**1.** Indicate the $u$-substitution.

(a) $\displaystyle\int 3x^2(1+x^3)^{25}\,dx = \int u^{25}\,du$ if $u =$ _____ and $du =$ _____.

(b) $\displaystyle\int 2x\sin x^2\,dx = \int \sin u\,du$ if $u =$ _____ and $du =$ _____.

(c) $\displaystyle\int \frac{18x}{1+9x^2}\,dx = \int \frac{1}{u}\,du$ if $u =$ _____ and $du =$ _____.

(d) $\displaystyle\int \frac{3}{1+9x^2}\,dx = \int \frac{1}{1+u^2}\,du$ if $u =$ _____ and $du =$ _____.

**2.** Supply the missing integrand corresponding to the indicated $u$-substitution.

(a) $\displaystyle\int 5(5x-3)^{-1/3}\,dx = \int$ _____ $du$; $u = 5x-3$

(b) $\displaystyle\int (3-\tan x)\sec^2 x\,dx = \int$ _____ $du$; $u = 3-\tan x$

(c) $\displaystyle\int \frac{\sqrt[3]{8+\sqrt{x}}}{\sqrt{x}}\,dx = \int$ _____ $du$; $u = 8+\sqrt{x}$

(d) $\displaystyle\int e^{3x}\,dx = \int$ _____ $du$; $u = 3x$

## EXERCISE SET 5.3 Graphing Utility C CAS

**1–12** Evaluate the integrals using the indicated substitutions.

**1.** (a) $\displaystyle\int 2x(x^2+1)^{23}\,dx$; $u = x^2+1$

(b) $\displaystyle\int \cos^3 x\sin x\,dx$; $u = \cos x$

**2.** (a) $\displaystyle\int \frac{1}{\sqrt{x}}\sin\sqrt{x}\,dx$; $u = \sqrt{x}$

(b) $\displaystyle\int \frac{3x\,dx}{\sqrt{4x^2+5}}$; $u = 4x^2+5$

**3.** (a) $\displaystyle\int \sec^2(4x+1)\,dx$; $u = 4x+1$

(b) $\displaystyle\int y\sqrt{1+2y^2}\,dy$; $u = 1+2y^2$

**4.** (a) $\displaystyle\int \sqrt{\sin\pi\theta}\cos\pi\theta\,d\theta$; $u = \sin\pi\theta$

(b) $\displaystyle\int (2x+7)(x^2+7x+3)^{4/5}\,dx$; $u = x^2+7x+3$

**5.** (a) $\displaystyle\int \cot x\csc^2 x\,dx$; $u = \cot x$

(b) $\displaystyle\int (1+\sin t)^9\cos t\,dt$; $u = 1+\sin t$

**6.** (a) $\displaystyle\int \cos 2x\,dx$; $u = 2x$ (b) $\displaystyle\int x\sec^2 x^2\,dx$; $u = x^2$

**7.** (a) $\displaystyle\int x^2\sqrt{1+x}\,dx$; $u = 1+x$

(b) $\displaystyle\int [\csc(\sin x)]^2\cos x\,dx$; $u = \sin x$

**8.** (a) $\displaystyle\int \sin(x-\pi)\,dx$; $u = x-\pi$

(b) $\displaystyle\int \frac{5x^4}{(x^5+1)^2}\,dx$; $u = x^5+1$

**9.** (a) $\displaystyle\int \frac{dx}{x\ln x}$; $u = \ln x$

(b) $\displaystyle\int e^{-5x}\,dx$; $u = -5x$

**10.** (a) $\displaystyle\int \frac{\sin 3\theta}{1+\cos 3\theta}\,d\theta;\ u = 1+\cos 3\theta$

(b) $\displaystyle\int \frac{e^x}{1+e^x}\,dx;\ u = 1+e^x$

**11.** (a) $\displaystyle\int \frac{x^2\,dx}{1+x^6};\ u = x^3$

(b) $\displaystyle\int \frac{dx}{x\sqrt{1-(\ln x)^2}};\ u = \ln x$

**12.** (a) $\displaystyle\int \frac{dx}{x\sqrt{9x^2-1}};\ u = 3x$

(b) $\displaystyle\int \frac{dx}{\sqrt{x}(1+x)};\ u = \sqrt{x}$

**FOCUS ON CONCEPTS**

**13.** Explain the connection between the chain rule for differentiation and the method of $u$-substitution for integration.

**14.** Explain how the substitution $u = ax + b$ helps to perform an integration in which the integrand is $f(ax+b)$, where $f(x)$ is an easy to integrate function.

**15–56** Evaluate the integrals using appropriate substitutions. ■

**15.** $\displaystyle\int (4x-3)^9\,dx$

**16.** $\displaystyle\int x^3\sqrt{5+x^4}\,dx$

**17.** $\displaystyle\int \sin 7x\,dx$

**18.** $\displaystyle\int \cos\frac{x}{3}\,dx$

**19.** $\displaystyle\int \sec 4x\tan 4x\,dx$

**20.** $\displaystyle\int \sec^2 5x\,dx$

**21.** $\displaystyle\int e^{2x}\,dx$

**22.** $\displaystyle\int \frac{dx}{2x}$

**23.** $\displaystyle\int \frac{dx}{\sqrt{1-4x^2}}$

**24.** $\displaystyle\int \frac{dx}{1+16x^2}$

**25.** $\displaystyle\int t\sqrt{7t^2+12}\,dt$

**26.** $\displaystyle\int \frac{x}{\sqrt{4-5x^2}}\,dx$

**27.** $\displaystyle\int \frac{6}{(1-2x)^3}\,dx$

**28.** $\displaystyle\int \frac{x^2+1}{\sqrt{x^3+3x}}\,dx$

**29.** $\displaystyle\int \frac{x^3}{(5x^4+2)^3}\,dx$

**30.** $\displaystyle\int \frac{\sin(1/x)}{3x^2}\,dx$

**31.** $\displaystyle\int e^{\sin x}\cos x\,dx$

**32.** $\displaystyle\int x^3 e^{x^4}\,dx$

**33.** $\displaystyle\int x^2 e^{-2x^3}\,dx$

**34.** $\displaystyle\int \frac{e^x+e^{-x}}{e^x-e^{-x}}\,dx$

**35.** $\displaystyle\int \frac{e^x}{1+e^{2x}}\,dx$

**36.** $\displaystyle\int \frac{t}{t^4+1}\,dt$

**37.** $\displaystyle\int \frac{\sin(5/x)}{x^2}\,dx$

**38.** $\displaystyle\int \frac{\sec^2(\sqrt{x})}{\sqrt{x}}\,dx$

**39.** $\displaystyle\int \cos^4 3t\sin 3t\,dt$

**40.** $\displaystyle\int \cos 2t\sin^5 2t\,dt$

**41.** $\displaystyle\int x\sec^2(x^2)\,dx$

**42.** $\displaystyle\int \frac{\cos 4\theta}{(1+2\sin 4\theta)^4}\,d\theta$

**43.** $\displaystyle\int \cos 4\theta\sqrt{2-\sin 4\theta}\,d\theta$

**44.** $\displaystyle\int \tan^3 5x\sec^2 5x\,dx$

**45.** $\displaystyle\int \frac{\sec^2 x\,dx}{\sqrt{1-\tan^2 x}}$

**46.** $\displaystyle\int \frac{\sin\theta}{\cos^2\theta+1}\,d\theta$

**47.** $\displaystyle\int \sec^3 2x\tan 2x\,dx$

**48.** $\displaystyle\int [\sin(\sin\theta)]\cos\theta\,d\theta$

**49.** $\displaystyle\int \frac{dx}{e^x}$

**50.** $\displaystyle\int \sqrt{e^x}\,dx$

**51.** $\displaystyle\int \frac{dx}{\sqrt{x}\,e^{(2\sqrt{x})}}$

**52.** $\displaystyle\int \frac{e^{\sqrt{2y+1}}}{\sqrt{2y+1}}\,dy$

**53.** $\displaystyle\int \frac{y}{\sqrt{2y+1}}\,dy$

**54.** $\displaystyle\int x\sqrt{4-x}\,dx$

**55.** $\displaystyle\int \sin^3 2\theta\,d\theta$

**56.** $\displaystyle\int \sec^4 3\theta\,d\theta$ [*Hint:* Apply a trigonometric identity.]

**57–60** Evaluate each integral by first modifying the form of the integrand and then making an appropriate substitution, if needed. ■

**57.** $\displaystyle\int \frac{t+1}{t}\,dt$

**58.** $\displaystyle\int e^{2\ln x}\,dx$

**59.** $\displaystyle\int [\ln(e^x)+\ln(e^{-x})]\,dx$

**60.** $\displaystyle\int \cot x\,dx$

**61–62** Evaluate the integrals with the aid of Formulas (5), (6), and (7). ■

**61.** (a) $\displaystyle\int \frac{dx}{\sqrt{9-x^2}}$ (b) $\displaystyle\int \frac{dx}{5+x^2}$ (c) $\displaystyle\int \frac{dx}{x\sqrt{x^2-\pi}}$

**62.** (a) $\displaystyle\int \frac{e^x}{4+e^{2x}}\,dx$ (b) $\displaystyle\int \frac{dx}{\sqrt{9-4x^2}}$ (c) $\displaystyle\int \frac{dy}{y\sqrt{5y^2-3}}$

**63–65** Evaluate the integrals assuming that $n$ is a positive integer and $b \neq 0$. ■

**63.** $\displaystyle\int (a+bx)^n\,dx$

**64.** $\displaystyle\int \sqrt[n]{a+bx}\,dx$

**65.** $\displaystyle\int \sin^n(a+bx)\cos(a+bx)\,dx$

C **66.** Use a CAS to check the answers you obtained in Exercises 63–65. If the answer produced by the CAS does not match yours, show that the two answers are equivalent. [*Suggestion: Mathematica* users may find it helpful to apply the Simplify command to the answer.]

**FOCUS ON CONCEPTS**

**67.** (a) Evaluate the integral $\int \sin x\cos x\,dx$ by two methods: first by letting $u = \sin x$, and then by letting $u = \cos x$.

(b) Explain why the two apparently different answers obtained in part (a) are really equivalent.

**68.** (a) Evaluate the integral $\int (5x-1)^2\,dx$ by two methods: first square and integrate, then let $u = 5x-1$.

(b) Explain why the two apparently different answers obtained in part (a) are really equivalent.

**69–72** Solve the initial-value problems. ■

**69.** $\dfrac{dy}{dx} = \sqrt{5x+1},\ y(3) = -2$

**70.** $\dfrac{dy}{dx} = 2 + \sin 3x,\ y(\pi/3) = 0$

**71.** $\dfrac{dy}{dt} = -e^{2t},\ y(0) = 6$

**72.** $\dfrac{dy}{dt} = \dfrac{1}{25+9t^2},\ y\left(-\dfrac{5}{3}\right) = \dfrac{\pi}{30}$

**73.** (a) Evaluate $\int [x/\sqrt{x^2+1}]\,dx$.
(b) Use a graphing utility to generate some typical integral curves of $f(x) = x/\sqrt{x^2+1}$ over the interval $(-5, 5)$.

**74.** (a) Evaluate $\int [x/(x^2+1)]\,dx$.
(b) Use a graphing utility to generate some typical integral curves of $f(x) = x/(x^2+1)$ over the interval $(-5, 5)$.

**75.** Find a function $f$ such that the slope of the tangent line at a point $(x, y)$ on the curve $y = f(x)$ is $\sqrt{3x+1}$ and the curve passes through the point $(0, 1)$.

**76.** A population of minnows in a lake is estimated to be 100,000 at the beginning of the year 2010. Suppose that $t$ years after the beginning of 2010 the rate of growth of the population $p(t)$ (in thousands) is given by $p'(t) = (3 + 0.12t)^{3/2}$. Estimate the projected population at the beginning of the year 2015.

**77.** Let $y(t)$ denote the number of *E. coli* cells in a container of nutrient solution $t$ minutes after the start of an experiment. Assume that $y(t)$ is modeled by the initial-value problem

$$\frac{dy}{dt} = (\ln 2)2^{t/20}, \qquad y(0) = 20$$

Use this model to estimate the number of *E. coli* cells in the container 2 hours after the start of the experiment.

**78.** Derive integration Formula (6).

**79.** Derive integration Formula (7).

**80.** **Writing** If you want to evaluate an integral by $u$-substitution, how do you decide what part of the integrand to choose for $u$?

**81.** **Writing** The evaluation of an integral can sometimes result in apparently different answers (Exercises 67 and 68). Explain why this occurs and give an example. How might you show that two apparently different answers are actually equivalent?

## ✔ QUICK CHECK ANSWERS 5.3

**1.** (a) $1 + x^3$; $3x^2\,dx$ (b) $x^2$; $2x\,dx$ (c) $1 + 9x^2$; $18x\,dx$ (d) $3x$; $3\,dx$ **2.** (a) $u^{-1/3}$ (b) $-u$ (c) $2\sqrt[3]{u}$ (d) $\frac{1}{3}e^u$

# 5.4 THE DEFINITION OF AREA AS A LIMIT; SIGMA NOTATION

*Our main goal in this section is to use the rectangle method to give a precise mathematical definition of the "area under a curve."*

## SIGMA NOTATION

To simplify our computations, we will begin by discussing a useful notation for expressing lengthy sums in a compact form. This notation is called ***sigma notation*** or ***summation notation*** because it uses the uppercase Greek letter $\Sigma$ (sigma) to denote various kinds of sums. To illustrate how this notation works, consider the sum

$$1^2 + 2^2 + 3^2 + 4^2 + 5^2$$

in which each term is of the form $k^2$, where $k$ is one of the integers from 1 to 5. In sigma notation this sum can be written as

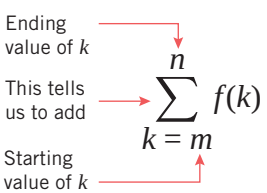
$$\sum_{k=1}^{5} k^2$$

which is read "the summation of $k^2$, where $k$ runs from 1 to 5." The notation tells us to form the sum of the terms that result when we substitute successive integers for $k$ in the expression $k^2$, starting with $k = 1$ and ending with $k = 5$.

More generally, if $f(k)$ is a function of $k$, and if $m$ and $n$ are integers such that $m \le n$, then

$$\sum_{k=m}^{n} f(k) \tag{1}$$

denotes the sum of the terms that result when we substitute successive integers for $k$, starting with $k = m$ and ending with $k = n$ (Figure 5.4.1).



▲ **Figure 5.4.1**

### ▶ Example 1

$$\sum_{k=4}^{8} k^3 = 4^3 + 5^3 + 6^3 + 7^3 + 8^3$$

$$\sum_{k=1}^{5} 2k = 2 \cdot 1 + 2 \cdot 2 + 2 \cdot 3 + 2 \cdot 4 + 2 \cdot 5 = 2 + 4 + 6 + 8 + 10$$

$$\sum_{k=0}^{5} (2k + 1) = 1 + 3 + 5 + 7 + 9 + 11$$

$$\sum_{k=0}^{5} (-1)^k (2k + 1) = 1 - 3 + 5 - 7 + 9 - 11$$

$$\sum_{k=-3}^{1} k^3 = (-3)^3 + (-2)^3 + (-1)^3 + 0^3 + 1^3 = -27 - 8 - 1 + 0 + 1$$

$$\sum_{k=1}^{3} k \sin\left(\frac{k\pi}{5}\right) = \sin\frac{\pi}{5} + 2\sin\frac{2\pi}{5} + 3\sin\frac{3\pi}{5} \quad \blacktriangleleft$$

The numbers $m$ and $n$ in (1) are called, respectively, the ***lower*** and ***upper limits of summation***; and the letter $k$ is called the ***index of summation***. It is not essential to use $k$ as the index of summation; any letter not reserved for another purpose will do. For example,

$$\sum_{i=1}^{6} \frac{1}{i}, \quad \sum_{j=1}^{6} \frac{1}{j}, \quad \text{and} \quad \sum_{n=1}^{6} \frac{1}{n}$$

all denote the sum

$$1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6}$$

If the upper and lower limits of summation are the same, then the "sum" in (1) reduces to a single term. For example,

$$\sum_{k=2}^{2} k^3 = 2^3 \quad \text{and} \quad \sum_{i=1}^{1} \frac{1}{i+2} = \frac{1}{1+2} = \frac{1}{3}$$

In the sums

$$\sum_{i=1}^{5} 2 \quad \text{and} \quad \sum_{j=0}^{2} x^3$$

the expression to the right of the $\Sigma$ sign does not involve the index of summation. In such cases, we take all the terms in the sum to be the same, with one term for each allowable value of the summation index. Thus,

$$\sum_{i=1}^{5} 2 = 2 + 2 + 2 + 2 + 2 \quad \text{and} \quad \sum_{j=0}^{2} x^3 = x^3 + x^3 + x^3$$

## CHANGING THE LIMITS OF SUMMATION

A sum can be written in more than one way using sigma notation with different limits of summation and correspondingly different summands. For example,

$$\sum_{i=1}^{5} 2i = 2 + 4 + 6 + 8 + 10 = \sum_{j=0}^{4} (2j + 2) = \sum_{k=3}^{7} (2k - 4)$$

On occasion we will want to change the sigma notation for a given sum to a sigma notation with different limits of summation.

## PROPERTIES OF SUMS

When stating general properties of sums it is often convenient to use a subscripted letter such as $a_k$ in place of the function notation $f(k)$. For example,

$$\sum_{k=1}^{5} a_k = a_1 + a_2 + a_3 + a_4 + a_5 = \sum_{j=1}^{5} a_j = \sum_{k=-1}^{3} a_{k+2}$$

$$\sum_{k=1}^{n} a_k = a_1 + a_2 + \cdots + a_n = \sum_{j=1}^{n} a_j = \sum_{k=-1}^{n-2} a_{k+2}$$

Our first properties provide some basic rules for manipulating sums.

**5.4.1 THEOREM**

(*a*) $\displaystyle\sum_{k=1}^{n} ca_k = c\sum_{k=1}^{n} a_k$ (*if $c$ does not depend on $k$*)

(*b*) $\displaystyle\sum_{k=1}^{n} (a_k + b_k) = \sum_{k=1}^{n} a_k + \sum_{k=1}^{n} b_k$

(*c*) $\displaystyle\sum_{k=1}^{n} (a_k - b_k) = \sum_{k=1}^{n} a_k - \sum_{k=1}^{n} b_k$

We will prove parts (*a*) and (*b*) and leave part (*c*) as an exercise.

**PROOF (*a*)**

$$\sum_{k=1}^{n} ca_k = ca_1 + ca_2 + \cdots + ca_n = c(a_1 + a_2 + \cdots + a_n) = c\sum_{k=1}^{n} a_k$$

**PROOF (*b*)**

$$\sum_{k=1}^{n} (a_k + b_k) = (a_1 + b_1) + (a_2 + b_2) + \cdots + (a_n + b_n)$$

$$= (a_1 + a_2 + \cdots + a_n) + (b_1 + b_2 + \cdots + b_n) = \sum_{k=1}^{n} a_k + \sum_{k=1}^{n} b_k \quad \blacksquare$$

Restating Theorem 5.4.1 in words:

(*a*) *A constant factor can be moved through a sigma sign.*

(*b*) *Sigma distributes across sums.*

(*c*) *Sigma distributes across differences.*

## SUMMATION FORMULAS

The following theorem lists some useful formulas for sums of powers of integers. The derivations of these formulas are given in Appendix D.

**TECHNOLOGY MASTERY**

If you have access to a CAS, it will provide a method for finding closed forms such as those in Theorem 5.4.2. Use your CAS to confirm the formulas in that theorem, and then find closed forms for

$$\sum_{k=1}^{n} k^4 \quad \text{and} \quad \sum_{k=1}^{n} k^5$$

**5.4.2 THEOREM**

$$(a)\quad \sum_{k=1}^{n} k = 1 + 2 + \cdots + n = \frac{n(n+1)}{2}$$

$$(b)\quad \sum_{k=1}^{n} k^2 = 1^2 + 2^2 + \cdots + n^2 = \frac{n(n+1)(2n+1)}{6}$$

$$(c)\quad \sum_{k=1}^{n} k^3 = 1^3 + 2^3 + \cdots + n^3 = \left[\frac{n(n+1)}{2}\right]^2$$

**▶ Example 2** Evaluate $\displaystyle\sum_{k=1}^{30} k(k+1)$.

**TECHNOLOGY MASTERY**

Many calculating utilities provide some way of evaluating sums expressed in sigma notation. If your utility has this capability, use it to confirm that the result in Example 2 is correct.

***Solution.***

$$\sum_{k=1}^{30} k(k+1) = \sum_{k=1}^{30} (k^2 + k) = \sum_{k=1}^{30} k^2 + \sum_{k=1}^{30} k$$

$$= \frac{30(31)(61)}{6} + \frac{30(31)}{2} = 9920$$

Theorem 5.4.2(*a*), (*b*) ◀

In formulas such as

$$\sum_{k=1}^{n} k = \frac{n(n+1)}{2} \quad \text{or} \quad 1 + 2 + \cdots + n = \frac{n(n+1)}{2}$$

the left side of the equality is said to express the sum in ***open form*** and the right side is said to express it in ***closed form***. The open form indicates the summands and the closed form is an explicit formula for the sum.

**▶ Example 3** Express $\displaystyle\sum_{k=1}^{n} (3+k)^2$ in closed form.

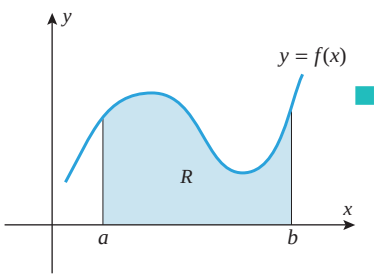
***Solution.***

$$\sum_{k=1}^{n} (3+k)^2 = 4^2 + 5^2 + \cdots + (3+n)^2$$

$$= [1^2 + 2^2 + 3^3 + 4^2 + 5^2 + \cdots + (3+n)^2] - [1^2 + 2^2 + 3^2]$$

$$= \left(\sum_{k=1}^{3+n} k^2\right) - 14$$

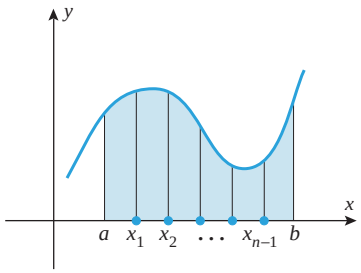
$$= \frac{(3+n)(4+n)(7+2n)}{6} - 14 = \frac{1}{6}(73n + 21n^2 + 2n^3)$$ ◀



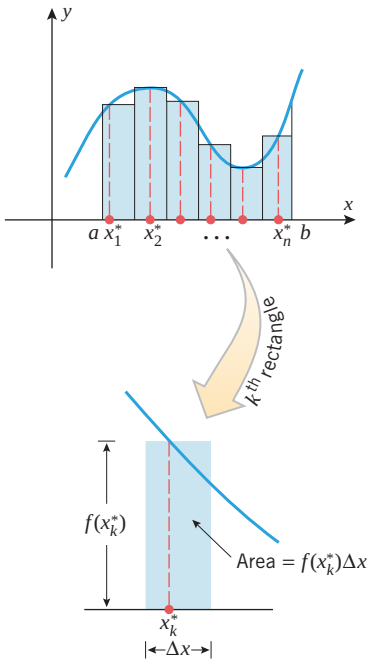
▲ Figure 5.4.2

## A DEFINITION OF AREA

We now turn to the problem of giving a precise definition of what is meant by the "area under a curve." Specifically, suppose that the function $f$ is continuous and nonnegative on the interval $[a, b]$, and let $R$ denote the region bounded below by the $x$-axis, bounded on the sides by the vertical lines $x = a$ and $x = b$, and bounded above by the curve $y = f(x)$ (Figure 5.4.2). Using the rectangle method of Section 5.1, we can motivate a definition for the area of $R$ as follows:



▲ Figure 5.4.3



▲ Figure 5.4.4

- Divide the interval $[a, b]$ into $n$ equal subintervals by inserting $n - 1$ equally spaced points between $a$ and $b$, and denote those points by

$$x_1, x_2, \ldots, x_{n-1}$$

(Figure 5.4.3). Each of these subintervals has width $(b - a)/n$, which is customarily denoted by

$$\Delta x = \frac{b - a}{n}$$

- Over each subinterval construct a rectangle whose height is the value of $f$ at an arbitrarily selected point in the subinterval. Thus, if

$$x_1^*, x_2^*, \ldots, x_n^*$$

denote the points selected in the subintervals, then the rectangles will have heights $f(x_1^*), f(x_2^*), \ldots, f(x_n^*)$ and areas

$$f(x_1^*)\Delta x, \quad f(x_2^*)\Delta x, \ldots, \quad f(x_n^*)\Delta x$$

(Figure 5.4.4).

- The union of the rectangles forms a region $R_n$ whose area can be regarded as an approximation to the area $A$ of the region $R$; that is,

$$A = \text{area}(R) \approx \text{area}(R_n) = f(x_1^*)\Delta x + f(x_2^*)\Delta x + \cdots + f(x_n^*)\Delta x$$

(Figure 5.4.5). This can be expressed more compactly in sigma notation as

$$A \approx \sum_{k=1}^{n} f(x_k^*)\Delta x$$

- Repeat the process using more and more subdivisions, and define the area of $R$ to be the "limit" of the areas of the approximating regions $R_n$ as $n$ increases without bound. That is, we define the area $A$ as

$$A = \lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x$$

In summary, we make the following definition.

**5.4.3 DEFINITION** (*Area Under a Curve*) If the function $f$ is continuous on $[a, b]$ and if $f(x) \geq 0$ for all $x$ in $[a, b]$, then the ***area*** $A$ under the curve $y = f(x)$ over the interval $[a, b]$ is defined by

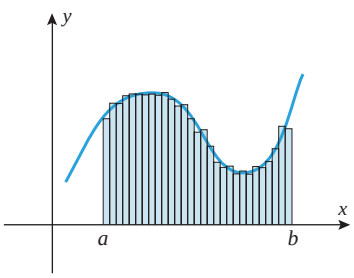
$$A = \lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x \tag{2}$$

The limit in (2) is interpreted to mean that given any number $\epsilon > 0$ the inequality

$$\left| A - \sum_{k=1}^{n} f(x_k^*)\Delta x \right| < \epsilon$$

holds when $n$ is sufficiently large, no matter how the points $x_k^*$ are selected.

**REMARK** There is a difference in interpretation between $\lim_{n \to +\infty}$ and $\lim_{x \to +\infty}$, where $n$ represents a positive integer and $x$ represents a real number. Later we will study limits of the type $\lim_{n \to +\infty}$ in detail, but for now suffice it to say that the computational techniques we have used for limits of type $\lim_{x \to +\infty}$ will also work for $\lim_{n \to +\infty}$.



▲ Figure 5.4.5 $\text{area}(R_n) \approx \text{area}(R)$

The values of $x_1^*, x_2^*, \ldots, x_n^*$ in (2) can be chosen arbitrarily, so it is conceivable that different choices of these values might produce different values of $A$. Were this to happen, then Definition 5.4.3 would not be an acceptable definition of area. Fortunately, this does not happen; it is proved in advanced courses that if $f$ is continuous (as we have assumed), then the same value of $A$ results no matter how the $x_k^*$ are chosen. In practice they are chosen in some systematic fashion, some common choices being

- the left endpoint of each subinterval
- the right endpoint of each subinterval
- the midpoint of each subinterval

To be more specific, suppose that the interval $[a, b]$ is divided into $n$ equal parts of length $\Delta x = (b - a)/n$ by the points $x_1, x_2, \ldots, x_{n-1}$, and let $x_0 = a$ and $x_n = b$ (Figure 5.4.6). Then,

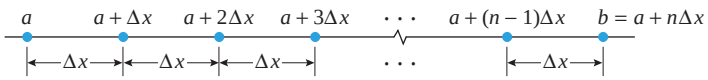
$$x_k = a + k\Delta x \quad \text{for } k = 0, 1, 2, \ldots, n$$

Thus, the left endpoint, right endpoint, and midpoint choices for $x_1^*, x_2^*, \ldots, x_n^*$ are given by

$$x_k^* = x_{k-1} = a + (k-1)\Delta x \qquad \text{Left endpoint} \tag{3}$$

$$x_k^* = x_k = a + k\Delta x \qquad \text{Right endpoint} \tag{4}$$

$$x_k^* = \tfrac{1}{2}(x_{k-1} + x_k) = a + \left(k - \tfrac{1}{2}\right)\Delta x \qquad \text{Midpoint} \tag{5}$$



▶ **Figure 5.4.6**

When applicable, the antiderivative method will be the method of choice for finding exact areas. However, the following examples will help to reinforce the ideas that we have just discussed.

▶ **Example 4** Use Definition 5.4.3 with $x_k^*$ as the right endpoint of each subinterval to find the area between the graph of $f(x) = x^2$ and the interval $[0, 1]$.

***Solution.*** The length of each subinterval is

$$\Delta x = \frac{b-a}{n} = \frac{1-0}{n} = \frac{1}{n}$$

so it follows from (4) that

$$x_k^* = a + k\Delta x = \frac{k}{n}$$

Thus,

$$\sum_{k=1}^{n} f(x_k^*)\Delta x = \sum_{k=1}^{n} (x_k^*)^2 \Delta x = \sum_{k=1}^{n} \left(\frac{k}{n}\right)^2 \frac{1}{n} = \frac{1}{n^3}\sum_{k=1}^{n} k^2$$

$$= \frac{1}{n^3}\left[\frac{n(n+1)(2n+1)}{6}\right] \qquad \text{Part } (b) \text{ of Theorem 5.4.2}$$

$$= \frac{1}{6}\left(\frac{n}{n} \cdot \frac{n+1}{n} \cdot \frac{2n+1}{n}\right) = \frac{1}{6}\left(1 + \frac{1}{n}\right)\left(2 + \frac{1}{n}\right)$$

from which it follows that

$$A = \lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x = \lim_{n \to +\infty} \left[\frac{1}{6}\left(1 + \frac{1}{n}\right)\left(2 + \frac{1}{n}\right)\right] = \frac{1}{3}$$

Observe that this is consistent with the results in Table 5.1.2 and the related discussion in Section 5.1. ◀

In the solution to Example 4 we made use of one of the "closed form" summation formulas from Theorem 5.4.2. The next result collects some consequences of Theorem 5.4.2 that can facilitate computations of area using Definition 5.4.3.

What pattern is revealed by parts (*b*)–(*d*) of Theorem 5.4.4? Does part (*a*) also fit this pattern? What would you conjecture to be the value of

$$\lim_{n\to+\infty}\frac{1}{n^m}\sum_{k=1}^{n}k^{m-1}\ ?$$

**5.4.4 THEOREM**

$$(a)\ \lim_{n\to+\infty}\frac{1}{n}\sum_{k=1}^{n}1=1 \qquad (b)\ \lim_{n\to+\infty}\frac{1}{n^2}\sum_{k=1}^{n}k=\frac{1}{2}$$

$$(c)\ \lim_{n\to+\infty}\frac{1}{n^3}\sum_{k=1}^{n}k^2=\frac{1}{3} \qquad (d)\ \lim_{n\to+\infty}\frac{1}{n^4}\sum_{k=1}^{n}k^3=\frac{1}{4}$$

The proof of Theorem 5.4.4 is left as an exercise for the reader.

▶ **Example 5** Use Definition 5.4.3 with $x_k^*$ as the midpoint of each subinterval to find the area under the parabola $y=f(x)=9-x^2$ and over the interval $[0,3]$.

***Solution.*** Each subinterval has length

$$\Delta x=\frac{b-a}{n}=\frac{3-0}{n}=\frac{3}{n}$$

so it follows from (5) that

$$x_k^*=a+\left(k-\frac{1}{2}\right)\Delta x=\left(k-\frac{1}{2}\right)\left(\frac{3}{n}\right)$$

Thus,

$$f(x_k^*)\Delta x=[9-(x_k^*)^2]\Delta x=\left[9-\left(k-\frac{1}{2}\right)^2\left(\frac{3}{n}\right)^2\right]\left(\frac{3}{n}\right)$$

$$=\left[9-\left(k^2-k+\frac{1}{4}\right)\left(\frac{9}{n^2}\right)\right]\left(\frac{3}{n}\right)$$

$$=\frac{27}{n}-\frac{27}{n^3}k^2+\frac{27}{n^3}k-\frac{27}{4n^3}$$

from which it follows that

$$A=\lim_{n\to+\infty}\sum_{k=1}^{n}f(x_k^*)\Delta x$$

$$=\lim_{n\to+\infty}\sum_{k=1}^{n}\left(\frac{27}{n}-\frac{27}{n^3}k^2+\frac{27}{n^3}k-\frac{27}{4n^3}\right)$$

$$=\lim_{n\to+\infty}27\left[\frac{1}{n}\sum_{k=1}^{n}1-\frac{1}{n^3}\sum_{k=1}^{n}k^2+\frac{1}{n}\left(\frac{1}{n^2}\sum_{k=1}^{n}k\right)-\frac{1}{4n^2}\left(\frac{1}{n}\sum_{k=1}^{n}1\right)\right]$$

$$=27\left[1-\frac{1}{3}+0\cdot\frac{1}{2}-0\cdot1\right]=18$$

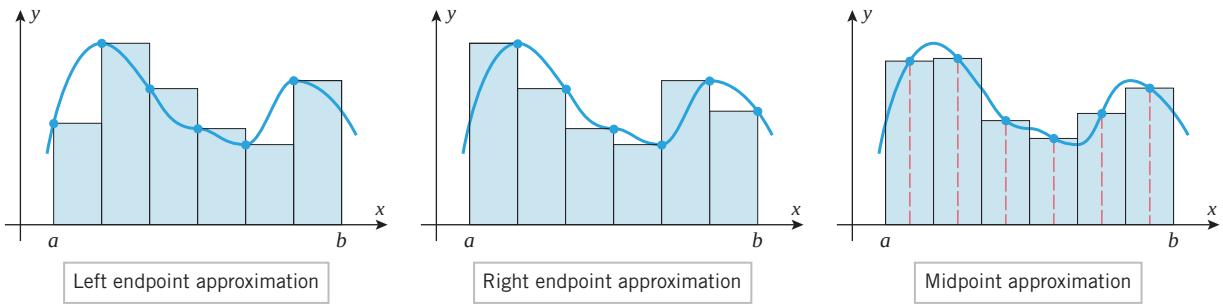
Theorem 5.4.4 ◀

## NUMERICAL APPROXIMATIONS OF AREA

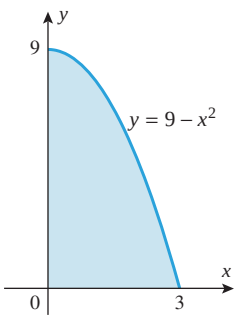
The antiderivative method discussed in Section 5.1 (and to be studied in more detail later) is an appropriate tool for finding the exact area under a curve when an antiderivative of the integrand can be found. However, if an antiderivative cannot be found, then we must resort to *approximating* the area. Definition 5.4.3 provides a way of doing this. It follows from this definition that if $n$ is large, then

$$\sum_{k=1}^{n} f(x_k^*)\Delta x = \Delta x \sum_{k=1}^{n} f(x_k^*) = \Delta x[f(x_1^*) + f(x_2^*) + \cdots + f(x_n^*)] \tag{6}$$

will be a good approximation to the area $A$. If one of Formulas (3), (4), or (5) is used to choose the $x_k^*$ in (6), then the result is called the ***left endpoint approximation***, the ***right endpoint approximation***, or the ***midpoint approximation***, respectively (Figure 5.4.7).



▲ **Figure 5.4.7**



▲ **Figure 5.4.8**

► **Example 6** Find the left endpoint, right endpoint, and midpoint approximations of the area under the curve $y = 9 - x^2$ over the interval $[0, 3]$ with $n = 10$, $n = 20$, and $n = 50$ (Figure 5.4.8). Compare the accuracies of these three methods.

***Solution.*** Details of the computations for the case $n = 10$ are shown to six decimal places in Table 5.4.1 and the results of all the computations are given in Table 5.4.2. We showed in Example 5 that the exact area is 18 (i.e., 18 square units), so in this case the midpoint approximation is more accurate than the endpoint approximations. This is also evident geometrically from Figure 5.4.9. You can also see from the figure that in this case the left endpoint approximation overestimates the area and the right endpoint approximation underestimates it. Later in the text we will investigate the error that results when an area is approximated by the midpoint rule. ◄

## NET SIGNED AREA

In Definition 5.4.3 we assumed that $f$ is continuous and nonnegative on the interval $[a, b]$. If $f$ is continuous and attains both positive and negative values on $[a, b]$, then the limit

$$\lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x \tag{7}$$

no longer represents the area between the curve $y = f(x)$ and the interval $[a, b]$ on the $x$-axis; rather, it represents a difference of areas—the area of the region that is above the interval $[a, b]$ and below the curve $y = f(x)$ minus the area of the region that is below the interval $[a, b]$ and above the curve $y = f(x)$. We call this the ***net signed area***

**Table 5.4.1**

$n = 10$, $\Delta x = (b - a)/n = (3 - 0)/10 = 0.3$

| | LEFT ENDPOINT APPROXIMATION | | RIGHT ENDPOINT APPROXIMATION | | MIDPOINT APPROXIMATION | |
|---|---|---|---|---|---|---|

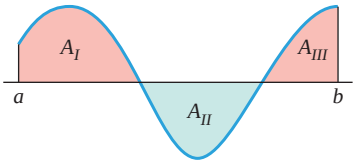
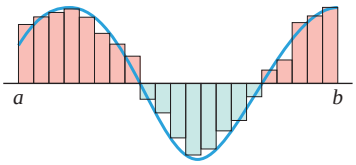
▲ **Figure 5.4.9**



(a)



(b)

▲ **Figure 5.4.10**

between the graph of $y = f(x)$ and the interval $[a, b]$. For example, in Figure 5.4.10*a*, the net signed area between the curve $y = f(x)$ and the interval $[a, b]$ is

$$(A_I + A_{III}) - A_{II} = \big[\text{area above } [a, b]\big] - \big[\text{area below } [a, b]\big]$$

To explain why the limit in (7) represents this net signed area, let us subdivide the interval $[a, b]$ in Figure 5.4.10*a* into $n$ equal subintervals and examine the terms in the sum

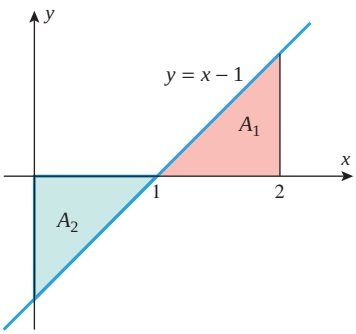
$$\sum_{k=1}^{n} f(x_k^*)\Delta x \tag{8}$$

If $f(x_k^*)$ is positive, then the product $f(x_k^*)\Delta x$ represents the area of the rectangle with height $f(x_k^*)$ and base $\Delta x$ (the pink rectangles in Figure 5.4.10*b*). However, if $f(x_k^*)$ is negative, then the product $f(x_k^*)\Delta x$ is the *negative* of the area of the rectangle with height $|f(x_k^*)|$ and base $\Delta x$ (the green rectangles in Figure 5.4.10*b*). Thus, (8) represents the total area of the pink rectangles minus the total area of the green rectangles. As $n$ increases, the pink rectangles fill out the regions with areas $A_I$ and $A_{III}$ and the green rectangles fill out the region with area $A_{II}$, which explains why the limit in (7) represents the signed area between $y = f(x)$ and the interval $[a, b]$. We formalize this in the following definition.

**5.4.5 DEFINITION** (***Net Signed Area***) If the function $f$ is continuous on $[a, b]$, then the ***net signed area*** $A$ between $y = f(x)$ and the interval $[a, b]$ is defined by

$$A = \lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x \tag{9}$$

As with Definition 5.4.3, it can be proved that the limit in (9) always exists and that the same value of $A$ results no matter how the points in the subintervals are chosen.



▲ **Figure 5.4.11**

Figure 5.4.11 shows the graph of $f(x) = x - 1$ over the interval $[0, 2]$. It is geometrically evident that the areas $A_1$ and $A_2$ in that figure are equal, so we expect the net signed area between the graph of $f$ and the interval $[0, 2]$ to be zero.

▶ **Example 7** Confirm that the net signed area between the graph of $f(x) = x - 1$ and the interval $[0, 2]$ is zero by using Definition 5.4.5 with $x_k^*$ chosen to be the left endpoint of each subinterval.

***Solution.*** Each subinterval has length

$$\Delta x = \frac{b - a}{n} = \frac{2 - 0}{n} = \frac{2}{n}$$

so it follows from (3) that

$$x_k^* = a + (k - 1)\Delta x = (k - 1)\left(\frac{2}{n}\right)$$

Thus,

$$\sum_{k=1}^{n} f(x_k^*)\Delta x = \sum_{k=1}^{n} (x_k^* - 1)\Delta x = \sum_{k=1}^{n} \left[(k - 1)\left(\frac{2}{n}\right) - 1\right]\left(\frac{2}{n}\right)$$

$$= \sum_{k=1}^{n} \left[\left(\frac{4}{n^2}\right)k - \frac{4}{n^2} - \frac{2}{n}\right]$$

from which it follows that

$$A = \lim_{n\to+\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x = \lim_{n\to+\infty} \left[ 4\left(\frac{1}{n^2}\sum_{k=1}^{n} k\right) - \frac{4}{n}\left(\frac{1}{n}\sum_{k=1}^{n} 1\right) - 2\left(\frac{1}{n}\sum_{k=1}^{n} 1\right)\right]$$

$$= 4\left(\frac{1}{2}\right) - 0 \cdot 1 - 2 \cdot 1 = 0 \qquad \text{Theorem 5.4.4}$$

This confirms that the net signed area is zero. ◀

## ✔ QUICK CHECK EXERCISES 5.4 *(See page 352 for answers.)*

**1.** (a) Write the sum in two ways:

$$\frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \frac{1}{8} = \sum_{k=1}^{4} _____ = \sum_{j=0}^{3} _____$$

(b) Express the sum $10 + 10^2 + 10^3 + 10^4 + 10^5$ using sigma notation.

**2.** Express the sums in closed form.

(a) $\displaystyle\sum_{k=1}^{n} k$ (b) $\displaystyle\sum_{k=1}^{n} (6k+1)$ (c) $\displaystyle\sum_{k=1}^{n} k^2$

**3.** Divide the interval $[1, 3]$ into $n = 4$ subintervals of equal length.

(a) Each subinterval has width _____.

(b) The left endpoints of the subintervals are _____.

(c) The midpoints of the subintervals are _____.

(d) The right endpoints of the subintervals are _____.

**4.** Find the left endpoint approximation for the area between the curve $y = x^2$ and the interval $[1, 3]$ using $n = 4$ equal subdivisions of the interval.

**5.** The right endpoint approximation for the net signed area between $y = f(x)$ and an interval $[a, b]$ is given by

$$\sum_{k=1}^{n} \frac{6k+1}{n^2}$$

Find the exact value of this net signed area.

## EXERCISE SET 5.4 C CAS

**1.** Evaluate.

(a) $\displaystyle\sum_{k=1}^{3} k^3$ (b) $\displaystyle\sum_{j=2}^{6} (3j-1)$ (c) $\displaystyle\sum_{i=-4}^{1} (i^2 - i)$

(d) $\displaystyle\sum_{n=0}^{5} 1$ (e) $\displaystyle\sum_{k=0}^{4} (-2)^k$ (f) $\displaystyle\sum_{n=1}^{6} \sin n\pi$

**2.** Evaluate.

(a) $\displaystyle\sum_{k=1}^{4} k \sin\frac{k\pi}{2}$ (b) $\displaystyle\sum_{j=0}^{5} (-1)^j$ (c) $\displaystyle\sum_{i=7}^{20} \pi^2$

(d) $\displaystyle\sum_{m=3}^{5} 2^{m+1}$ (e) $\displaystyle\sum_{n=1}^{6} \sqrt{n}$ (f) $\displaystyle\sum_{k=0}^{10} \cos k\pi$

**3–8** Write each expression in sigma notation but do not evaluate. ■

**3.** $1 + 2 + 3 + \cdots + 10$

**4.** $3 \cdot 1 + 3 \cdot 2 + 3 \cdot 3 + \cdots + 3 \cdot 20$

**5.** $2 + 4 + 6 + 8 + \cdots + 20$ **6.** $1 + 3 + 5 + 7 + \cdots + 15$

**7.** $1 - 3 + 5 - 7 + 9 - 11$ **8.** $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5}$

**9.** (a) Express the sum of the even integers from 2 to 100 in sigma notation.

(b) Express the sum of the odd integers from 1 to 99 in sigma notation.

**10.** Express in sigma notation.

(a) $a_1 - a_2 + a_3 - a_4 + a_5$

(b) $-b_0 + b_1 - b_2 + b_3 - b_4 + b_5$

(c) $a_0 + a_1 x + a_2 x^2 + \cdots + a_n x^n$

(d) $a^5 + a^4 b + a^3 b^2 + a^2 b^3 + a b^4 + b^5$

**11–16** Use Theorem 5.4.2 to evaluate the sums. Check your answers using the summation feature of a calculating utility. ■

**11.** $\displaystyle\sum_{k=1}^{100} k$ **12.** $\displaystyle\sum_{k=1}^{100} (7k+1)$ **13.** $\displaystyle\sum_{k=1}^{20} k^2$

**14.** $\displaystyle\sum_{k=4}^{20} k^2$ **15.** $\displaystyle\sum_{k=1}^{30} k(k-2)(k+2)$

**16.** $\displaystyle\sum_{k=1}^{6} (k - k^3)$

**17–20** Express the sums in closed form. ■

**17.** $\displaystyle\sum_{k=1}^{n} \frac{3k}{n}$ **18.** $\displaystyle\sum_{k=1}^{n-1} \frac{k^2}{n}$ **19.** $\displaystyle\sum_{k=1}^{n-1} \frac{k^3}{n^2}$

**20.** $\displaystyle\sum_{k=1}^{n} \left(\frac{5}{n} - \frac{2k}{n}\right)$

**21–24 True–False** Determine whether the statement is true or false. Explain your answer. ■

**21.** For all positive integers $n$

$$1^3 + 2^3 + \cdots + n^3 = (1 + 2 + \cdots + n)^2$$

**22.** The midpoint approximation is the average of the left endpoint approximation and the right endpoint approximation.

**23.** Every right endpoint approximation for the area under the graph of $y = x^2$ over an interval $[a, b]$ will be an overestimate.

**24.** For any continuous function $f$, the area between the graph of $f$ and an interval $[a, b]$ (on which $f$ is defined) is equal to the absolute value of the net signed area between the graph of $f$ and the interval $[a, b]$.

**FOCUS ON CONCEPTS**

**25.** (a) Write the first three and final two summands in the sum

$$\sum_{k=1}^{n} \left(2 + k \cdot \frac{3}{n}\right)^4 \frac{3}{n}$$

Explain why this sum gives the right endpoint approximation for the area under the curve $y = x^4$ over the interval $[2, 5]$.

(b) Show that a change in the index range of the sum in part (a) can produce the left endpoint approximation for the area under the curve $y = x^4$ over the interval $[2, 5]$.

**26.** For a function $f$ that is continuous on $[a, b]$, Definition 5.4.5 says that the net signed area $A$ between $y = f(x)$ and the interval $[a, b]$ is

$$A = \lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x$$

Give geometric interpretations for the symbols $n$, $x_k^*$, and $\Delta x$. Explain how to interpret the limit in this definition.

**27–30** Divide the specified interval into $n = 4$ subintervals of equal length and then compute

$$\sum_{k=1}^{4} f(x_k^*)\Delta x$$

with $x_k^*$ as (a) the left endpoint of each subinterval, (b) the midpoint of each subinterval, and (c) the right endpoint of each subinterval. Illustrate each part with a graph of $f$ that includes the rectangles whose areas are represented in the sum. ■

**27.** $f(x) = 3x + 1;\ [2, 6]$ **28.** $f(x) = 1/x;\ [1, 9]$

**29.** $f(x) = \cos x;\ [0, \pi]$ **30.** $f(x) = 2x - x^2;\ [-1, 3]$

C **31–34** Use a calculating utility with summation capabilities or a CAS to obtain an approximate value for the area between the curve $y = f(x)$ and the specified interval with $n = 10$, 20, and 50 subintervals using the (a) left endpoint, (b) midpoint, and (c) right endpoint approximations. ■

**31.** $f(x) = 1/x;\ [1, 2]$ **32.** $f(x) = 1/x^2;\ [1, 3]$

**33.** $f(x) = \sqrt{x};\ [0, 4]$ **34.** $f(x) = \sin x;\ [0, \pi/2]$

**35–40** Use Definition 5.4.3 with $x_k^*$ as the *right* endpoint of each subinterval to find the area under the curve $y = f(x)$ over the specified interval. ■

**35.** $f(x) = x/2;\ [1, 4]$ **36.** $f(x) = 5 - x;\ [0, 5]$

**37.** $f(x) = 9 - x^2;\ [0, 3]$ **38.** $f(x) = 4 - \frac{1}{4}x^2;\ [0, 3]$

**39.** $f(x) = x^3;\ [2, 6]$ **40.** $f(x) = 1 - x^3;\ [-3, -1]$

**41–44** Use Definition 5.4.3 with $x_k^*$ as the *left* endpoint of each subinterval to find the area under the curve $y = f(x)$ over the specified interval. ■

**41.** $f(x) = x/2;\ [1, 4]$ **42.** $f(x) = 5 - x;\ [0, 5]$

**43.** $f(x) = 9 - x^2;\ [0, 3]$ **44.** $f(x) = 4 - \frac{1}{4}x^2;\ [0, 3]$

**45–48** Use Definition 5.4.3 with $x_k^*$ as the *midpoint* of each subinterval to find the area under the curve $y = f(x)$ over the specified interval. ■

**45.** $f(x) = 2x;\ [0, 4]$ **46.** $f(x) = 6 - x;\ [1, 5]$

**47.** $f(x) = x^2;\ [0, 1]$ **48.** $f(x) = x^2;\ [-1, 1]$

**49–52** Use Definition 5.4.5 with $x_k^*$ as the *right* endpoint of each subinterval to find the net signed area between the curve $y = f(x)$ and the specified interval. ■

**49.** $f(x) = x;\ [-1, 1]$. Verify your answer with a simple geometric argument.

**50.** $f(x) = x;\ [-1, 2]$. Verify your answer with a simple geometric argument.

**51.** $f(x) = x^2 - 1;\ [0, 2]$ **52.** $f(x) = x^3;\ [-1, 1]$

**53.** (a) Show that the area under the graph of $y = x^3$ and over the interval $[0, b]$ is $b^4/4$.

(b) Find a formula for the area under $y = x^3$ over the interval $[a, b]$, where $a \geq 0$.

**54.** Find the area between the graph of $y = \sqrt{x}$ and the interval $[0, 1]$. [*Hint:* Use the result of Exercise 25 of Section 5.1.]

**55.** An artist wants to create a rough triangular design using uniform square tiles glued edge to edge. She places $n$ tiles in a row to form the base of the triangle and then makes each successive row two tiles shorter than the preceding row. Find a formula for the number of tiles used in the design. [*Hint:* Your answer will depend on whether $n$ is even or odd.]

**56.** An artist wants to create a sculpture by gluing together uniform spheres. She creates a rough rectangular base that has 50 spheres along one edge and 30 spheres along the other. She then creates successive layers by gluing spheres in the grooves of the preceding layer. How many spheres will there be in the sculpture?

**57–60** Consider the sum

$$\sum_{k=1}^{4}[(k+1)^3 - k^3] = [5^3 - 4^3] + [4^3 - 3^3] + [3^3 - 2^3] + [2^3 - 1^3] = 5^3 - 1^3 = 124$$

For convenience, the terms are listed in reverse order. Note how cancellation allows the entire sum to collapse like a telescope. A sum is said to ***telescope*** when part of each term cancels part of an adjacent term, leaving only portions of the first and last terms uncanceled. Evaluate the telescoping sums in these exercises. ■

**57.** $\displaystyle\sum_{k=5}^{17}(3^k - 3^{k-1})$

**58.** $\displaystyle\sum_{k=1}^{50}\left(\frac{1}{k} - \frac{1}{k+1}\right)$

**59.** $\displaystyle\sum_{k=2}^{20}\left(\frac{1}{k^2} - \frac{1}{(k-1)^2}\right)$

**60.** $\displaystyle\sum_{k=1}^{100}(2^{k+1} - 2^k)$

**61.** (a) Show that

$$\frac{1}{1\cdot 3} + \frac{1}{3\cdot 5} + \cdots + \frac{1}{(2n-1)(2n+1)} = \frac{n}{2n+1}$$

$$\left[\textit{Hint: } \frac{1}{(2n-1)(2n+1)} = \frac{1}{2}\left(\frac{1}{2n-1} - \frac{1}{2n+1}\right)\right]$$

(b) Use the result in part (a) to find

$$\lim_{n\to+\infty}\sum_{k=1}^{n}\frac{1}{(2k-1)(2k+1)}$$

**62.** (a) Show that

$$\frac{1}{1\cdot 2} + \frac{1}{2\cdot 3} + \frac{1}{3\cdot 4} + \cdots + \frac{1}{n(n+1)} = \frac{n}{n+1}$$

$$\left[\textit{Hint: } \frac{1}{n(n+1)} = \frac{1}{n} - \frac{1}{n+1}\right]$$

(b) Use the result in part (a) to find

$$\lim_{n\to+\infty}\sum_{k=1}^{n}\frac{1}{k(k+1)}$$

**63.** Let $\bar{x}$ denote the arithmetic average of the $n$ numbers $x_1, x_2, \ldots, x_n$. Use Theorem 5.4.1 to prove that

$$\sum_{i=1}^{n}(x_i - \bar{x}) = 0$$

**64.** Let

$$S = \sum_{k=0}^{n} ar^k$$

Show that $S - rS = a - ar^{n+1}$ and hence that

$$\sum_{k=0}^{n} ar^k = \frac{a - ar^{n+1}}{1-r} \quad (r \neq 1)$$

(A sum of this form is called a ***geometric sum***.)

**65.** By writing out the sums, determine whether the following are valid identities.

(a) $\displaystyle\int\left[\sum_{i=1}^{n} f_i(x)\right]dx = \sum_{i=1}^{n}\left[\int f_i(x)\,dx\right]$

(b) $\displaystyle\frac{d}{dx}\left[\sum_{i=1}^{n} f_i(x)\right] = \sum_{i=1}^{n}\left[\frac{d}{dx}[f_i(x)]\right]$

**66.** Which of the following are valid identities?

(a) $\displaystyle\sum_{i=1}^{n} a_i b_i = \sum_{i=1}^{n} a_i \sum_{i=1}^{n} b_i$ (b) $\displaystyle\sum_{i=1}^{n} a_i^2 = \left(\sum_{i=1}^{n} a_i\right)^2$

(c) $\displaystyle\sum_{i=1}^{n}\frac{a_i}{b_i} = \frac{\displaystyle\sum_{i=1}^{n} a_i}{\displaystyle\sum_{i=1}^{n} b_i}$ (d) $\displaystyle\sum_{i=1}^{n} a_i = \sum_{j=0}^{n-1} a_{j+1}$

**67.** Prove part (*c*) of Theorem 5.4.1.

**68.** Prove Theorem 5.4.4.

**69.** **Writing** What is *net signed area*? How does this concept expand our application of the rectangle method?

**70.** **Writing** Based on Example 6, one might conjecture that the midpoint approximation always provides a better approximation than either endpoint approximation. Discuss the merits of this conjecture.

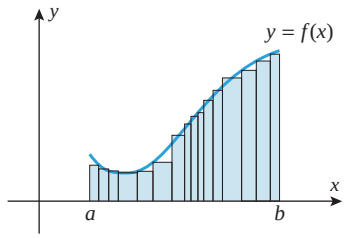
# 5.5 THE DEFINITE INTEGRAL

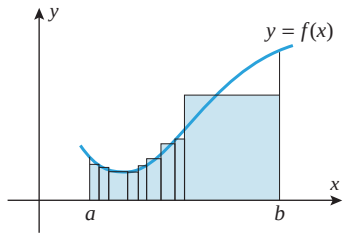
*In this section we will introduce the concept of a "definite integral," which will link the concept of area to other important concepts such as length, volume, density, probability, and work.*

## RIEMANN SUMS AND THE DEFINITE INTEGRAL

In our definition of net signed area (Definition 5.4.5), we assumed that for each positive number $n$, the interval $[a, b]$ was subdivided into $n$ subintervals of equal length to create bases for the approximating rectangles. For some functions it may be more convenient to use rectangles with different widths (see Making Connections Exercises 2 and 3); however, if we are to "exhaust" an area with rectangles of different widths, then it is important that successive subdivisions be constructed in such a way that the widths of all the rectangles approach zero as $n$ increases (Figure 5.5.1). Thus, we must preclude the kind of situation that occurs in Figure 5.5.2 in which the right half of the interval is never subdivided. If this kind of subdivision were allowed, the error in the approximation would not approach zero as $n$ increased.



▲ Figure 5.5.1



▲ Figure 5.5.2

A ***partition*** of the interval $[a, b]$ is a collection of points

$$a = x_0 < x_1 < x_2 < \cdots < x_{n-1} < x_n = b$$

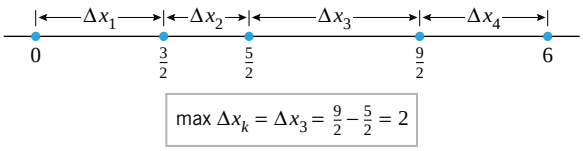
that divides $[a, b]$ into $n$ subintervals of lengths

$$\Delta x_1 = x_1 - x_0, \quad \Delta x_2 = x_2 - x_1, \quad \Delta x_3 = x_3 - x_2, \ldots, \quad \Delta x_n = x_n - x_{n-1}$$

The partition is said to be ***regular*** provided the subintervals all have the same length

$$\Delta x_k = \Delta x = \frac{b-a}{n}$$

For a regular partition, the widths of the approximating rectangles approach zero as $n$ is made large. Since this need not be the case for a general partition, we need some way to measure the "size" of these widths. One approach is to let $\max \Delta x_k$ denote the largest of the subinterval widths. The magnitude $\max \Delta x_k$ is called the ***mesh size*** of the partition. For example, Figure 5.5.3 shows a partition of the interval $[0, 6]$ into four subintervals with a mesh size of 2.



▶ Figure 5.5.3

If we are to generalize Definition 5.4.5 so that it allows for unequal subinterval widths, we must replace the constant length $\Delta x$ by the variable length $\Delta x_k$. When this is done the sum

$$\sum_{k=1}^{n} f(x_k^*)\Delta x \quad \text{is replaced by} \quad \sum_{k=1}^{n} f(x_k^*)\Delta x_k$$

We also need to replace the expression $n \to +\infty$ by an expression that guarantees us that the lengths of all subintervals approach zero. We will use the expression $\max \Delta x_k \to 0$ for this purpose. Based on our intuitive concept of area, we would then expect the net signed area $A$ between the graph of $f$ and the interval $[a, b]$ to satisfy the equation

$$A = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k$$

Some writers use the symbol $\|\Delta\|$ rather than $\max \Delta x_k$ for the mesh size of the partition, in which case $\max \Delta x_k \to 0$ would be replaced by $\|\Delta\| \to 0$.

(We will see in a moment that this is the case.) The limit that appears in this expression is one of the fundamental concepts of integral calculus and forms the basis for the following definition.

**5.5.1 DEFINITION** A function $f$ is said to be ***integrable*** on a finite closed interval $[a, b]$ if the limit

$$\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k$$

exists and does not depend on the choice of partitions or on the choice of the points $x_k^*$ in the subintervals. When this is the case we denote the limit by the symbol

$$\int_a^b f(x)\,dx = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k$$

which is called the ***definite integral*** of $f$ from $a$ to $b$. The numbers $a$ and $b$ are called the ***lower limit of integration*** and the ***upper limit of integration***, respectively, and $f(x)$ is called the ***integrand***.

The notation used for the definite integral deserves some comment. Historically, the expression "$f(x)\,dx$" was interpreted to be the "infinitesimal area" of a rectangle with height $f(x)$ and "infinitesimal" width $dx$. By "summing" these infinitesimal areas, the entire area under the curve was obtained. The integral symbol "$\int$" is an "elongated s" that was used to indicate this summation. For us, the integral symbol "$\int$" and the symbol "$dx$" can serve as reminders that the definite integral is actually a limit of a *summation* as $\Delta x_k \to 0$. The sum that appears in Definition 5.5.1 is called a ***Riemann sum***, and the definite integral is sometimes called the ***Riemann integral*** in honor of the German mathematician Bernhard Riemann who formulated many of the basic concepts of integral calculus. (The reason for the similarity in notation between the definite integral and the indefinite integral will become clear in the next section, where we will establish a link between the two types of "integration.")

**Georg Friedrich Bernhard Riemann (1826–1866)** German mathematician. Bernhard Riemann, as he is commonly known, was the son of a Protestant minister. He received his elementary education from his father and showed brilliance in arithmetic at an early age. In 1846 he enrolled at Göttingen University to study theology and philology, but he soon transferred to mathematics. He studied physics under W. E. Weber and mathematics under Carl Friedrich Gauss, whom some people consider to be the greatest mathematician who ever lived. In 1851 Riemann received his Ph.D. under Gauss, after which he remained at Göttingen to teach. In 1862, one month after his marriage, Riemann suffered an attack of pleuritis, and for the remainder of his life was an extremely sick man. He finally succumbed to tuberculosis in 1866 at age 39.

An interesting story surrounds Riemann's work in geometry. For his introductory lecture prior to becoming an associate professor, Riemann submitted three possible topics to Gauss. Gauss surprised Riemann by choosing the topic Riemann liked the least, the foundations of geometry. The lecture was like a scene from a movie. The old and failing Gauss, a giant in his day, watching intently as his brilliant and youthful protégé skillfully pieced together portions of the old man's own work into a complete and beautiful system. Gauss is said to have gasped with delight as the lecture neared its end, and on the way home he marveled at his student's brilliance. Gauss died shortly thereafter. The results presented by Riemann that day eventually evolved into a fundamental tool that Einstein used some 50 years later to develop relativity theory.

In addition to his work in geometry, Riemann made major contributions to the theory of complex functions and mathematical physics. The notion of the definite integral, as it is presented in most basic calculus courses, is due to him. Riemann's early death was a great loss to mathematics, for his mathematical work was brilliant and of fundamental importance.

[*Image: http://commons.wikimedia.org/wiki/File:Georg_Friedrich_Bernhard_Riemann.jpeg*]

The limit that appears in Definition 5.5.1 is somewhat different from the kinds of limits discussed in Chapter 1. Loosely phrased, the expression

$$\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k = L$$

is intended to convey the idea that we can force the Riemann sums to be as close as we please to $L$, regardless of how the values of $x_k^*$ are chosen, by making the mesh size of the partition sufficiently small. While it is possible to give a more formal definition of this limit, we will simply rely on intuitive arguments when applying Definition 5.5.1.

Although a function need not be continuous on an interval to be integrable on that interval (Exercise 42), we will be interested primarily in definite integrals of continuous functions. The following theorem, which we will state without proof, says that if a function is continuous on a finite closed interval, then it is integrable on that interval, and its definite integral is the net signed area between the graph of the function and the interval.

**5.5.2 THEOREM** *If a function $f$ is continuous on an interval $[a, b]$, then $f$ is integrable on $[a, b]$, and the net signed area $A$ between the graph of $f$ and the interval $[a, b]$ is*

$$A = \int_a^b f(x)\,dx \tag{1}$$

**REMARK** Formula (1) follows from the integrability of $f$, since the integrability allows us to use any partitions to evaluate the integral. In particular, if we use *regular* partitions of $[a, b]$, then

$$\Delta x_k = \Delta x = \frac{b-a}{n}$$

for all values of $k$. This implies that $\max \Delta x_k = (b-a)/n$, from which it follows that $\max \Delta x_k \to 0$ if and only if $n \to +\infty$. Thus,

$$\int_a^b f(x)\,dx = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k = \lim_{n \to +\infty} \sum_{k=1}^{n} f(x_k^*)\Delta x = A$$

In the simplest cases, definite integrals of continuous functions can be calculated using formulas from plane geometry to compute signed areas.

In Example 1, it is understood that the units of area are the squared units of length, even though we have not stated the units of length explicitly.

▶ **Example 1** Sketch the region whose area is represented by the definite integral, and evaluate the integral using an appropriate formula from geometry.

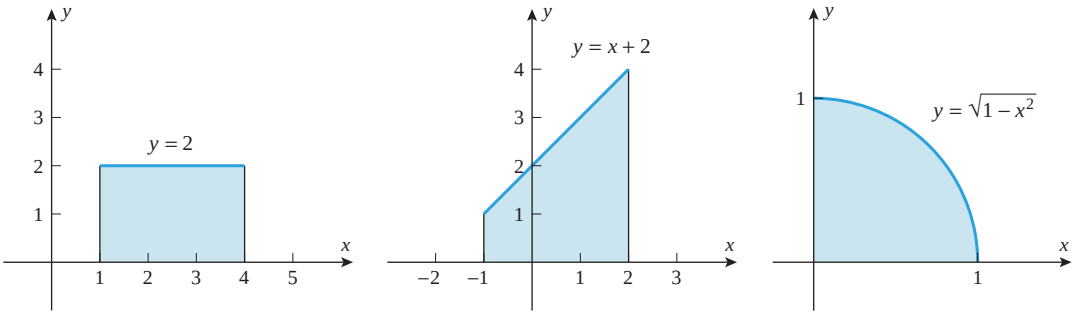
$$\text{(a)} \int_1^4 2\,dx \qquad \text{(b)} \int_{-1}^2 (x+2)\,dx \qquad \text{(c)} \int_0^1 \sqrt{1-x^2}\,dx$$

***Solution (a).*** The graph of the integrand is the horizontal line $y = 2$, so the region is a rectangle of height 2 extending over the interval from 1 to 4 (Figure 5.5.4*a*). Thus,

$$\int_1^4 2\,dx = (\text{area of rectangle}) = 2(3) = 6$$

***Solution (b).*** The graph of the integrand is the line $y = x + 2$, so the region is a trapezoid whose base extends from $x = -1$ to $x = 2$ (Figure 5.5.4*b*). Thus,

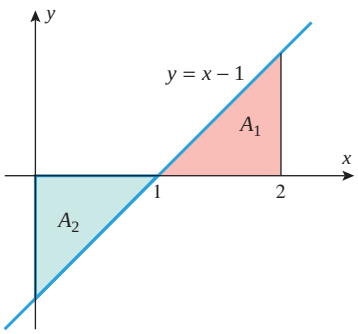
$$\int_{-1}^2 (x+2)\,dx = (\text{area of trapezoid}) = \frac{1}{2}(1+4)(3) = \frac{15}{2}$$



▲ Figure 5.5.4

***Solution (c).*** The graph of $y = \sqrt{1 - x^2}$ is the upper semicircle of radius 1, centered at the origin, so the region is the right quarter-circle extending from $x = 0$ to $x = 1$ (Figure 5.5.4*c*). Thus,

$$\int_0^1 \sqrt{1 - x^2}\, dx = (\text{area of quarter-circle}) = \frac{1}{4}\pi(1^2) = \frac{\pi}{4} \quad \blacktriangleleft$$



▲ Figure 5.5.5

**▶ Example 2** Evaluate

$$\text{(a)} \int_0^2 (x - 1)\, dx \qquad \text{(b)} \int_0^1 (x - 1)\, dx$$

***Solution.*** The graph of $y = x - 1$ is shown in Figure 5.5.5, and we leave it for you to verify that the shaded triangular regions both have area $\frac{1}{2}$. Over the interval $[0, 2]$ the net signed area is $A_1 - A_2 = \frac{1}{2} - \frac{1}{2} = 0$, and over the interval $[0, 1]$ the net signed area is $-A_2 = -\frac{1}{2}$. Thus,

$$\int_0^2 (x - 1)\, dx = 0 \quad \text{and} \quad \int_0^1 (x - 1)\, dx = -\tfrac{1}{2}$$

(Recall that in Example 7 of Section 5.4, we used Definition 5.4.5 to show that the net signed area between the graph of $y = x - 1$ and the interval $[0, 2]$ is zero.) ◀

## PROPERTIES OF THE DEFINITE INTEGRAL

It is assumed in Definition 5.5.1 that $[a, b]$ is a finite closed interval with $a < b$, and hence the upper limit of integration in the definite integral is greater than the lower limit of integration. However, it will be convenient to extend this definition to allow for cases in which the upper and lower limits of integration are equal or the lower limit of integration is greater than the upper limit of integration. For this purpose we make the following special definitions.

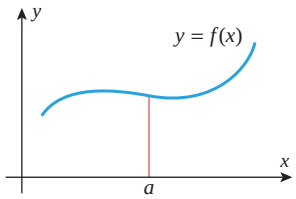
**5.5.3 DEFINITION**

(a) If $a$ is in the domain of $f$, we define

$$\int_a^a f(x)\, dx = 0$$

(b) If $f$ is integrable on $[a, b]$, then we define

$$\int_b^a f(x)\, dx = -\int_a^b f(x)\, dx$$



The area between $y = f(x)$ and $a$ is zero.

▲ Figure 5.5.6

Part (a) of this definition is consistent with the intuitive idea that the area between a point on the $x$-axis and a curve $y = f(x)$ should be zero (Figure 5.5.6). Part (b) of the definition is simply a useful convention; it states that interchanging the limits of integration reverses the sign of the integral.

### ▶ Example 3

(a) $\displaystyle\int_1^1 x^2\,dx = 0$

(b) $\displaystyle\int_1^0 \sqrt{1-x^2}\,dx = -\int_0^1 \sqrt{1-x^2}\,dx = -\frac{\pi}{4}$ ◀

Example 1(c)

Because definite integrals are defined as limits, they inherit many of the properties of limits. For example, we know that constants can be moved through limit signs and that the limit of a sum or difference is the sum or difference of the limits. Thus, you should not be surprised by the following theorem, which we state without formal proof.

**5.5.4 THEOREM** *If $f$ and $g$ are integrable on $[a, b]$ and if $c$ is a constant, then $cf$, $f + g$, and $f - g$ are integrable on $[a, b]$ and*

$$(a)\quad \int_a^b cf(x)\,dx = c\int_a^b f(x)\,dx$$

$$(b)\quad \int_a^b [f(x) + g(x)]\,dx = \int_a^b f(x)\,dx + \int_a^b g(x)\,dx$$

$$(c)\quad \int_a^b [f(x) - g(x)]\,dx = \int_a^b f(x)\,dx - \int_a^b g(x)\,dx$$

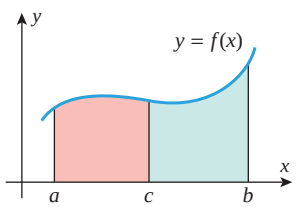
Part $(b)$ of this theorem can be extended to more than two functions. More precisely,

$$\int_a^b [f_1(x) + f_2(x) + \cdots + f_n(x)]\,dx = \int_a^b f_1(x)\,dx + \int_a^b f_2(x)\,dx + \cdots + \int_a^b f_n(x)\,dx$$

Some properties of definite integrals can be motivated by interpreting the integral as an area. For example, if $f$ is continuous and nonnegative on the interval $[a, b]$, and if $c$ is a point between $a$ and $b$, then the area under $y = f(x)$ over the interval $[a, b]$ can be split into two parts and expressed as the area under the graph from $a$ to $c$ plus the area under the graph from $c$ to $b$ (Figure 5.5.7), that is,

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx$$

This is a special case of the following theorem about definite integrals, which we state without proof.



▲ Figure 5.5.7

**5.5.5 THEOREM** *If $f$ is integrable on a closed interval containing the three points $a$, $b$, and $c$, then*

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx$$

*no matter how the points are ordered.*

The following theorem, which we state without formal proof, can also be motivated by interpreting definite integrals as areas.

**5.5.6 THEOREM**

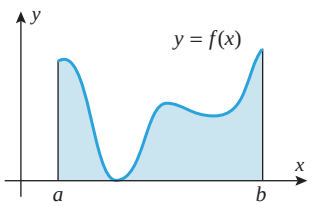
(*a*) *If $f$ is integrable on $[a, b]$ and $f(x) \geq 0$ for all $x$ in $[a, b]$, then*

$$\int_a^b f(x)\,dx \geq 0$$

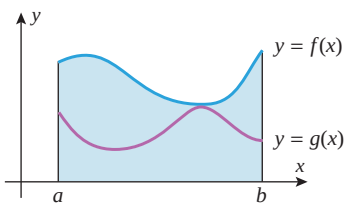
(*b*) *If $f$ and $g$ are integrable on $[a, b]$ and $f(x) \geq g(x)$ for all $x$ in $[a, b]$, then*

$$\int_a^b f(x)\,dx \geq \int_a^b g(x)\,dx$$

Part (*b*) of Theorem 5.5.6 states that the direction (sometimes called the *sense*) of the inequality $f(x) \geq g(x)$ is unchanged if one integrates both sides. Moreover, if $b > a$, then both parts of the theorem remain true if $\geq$ is replaced by $\leq$, $>$, or $<$ throughout.



▲ **Figure 5.5.8**



▲ **Figure 5.5.9**

Geometrically, part (*a*) of this theorem states the obvious fact that if $f$ is nonnegative on $[a, b]$, then the net signed area between the graph of $f$ and the interval $[a, b]$ is also nonnegative (Figure 5.5.8). Part (*b*) has its simplest interpretation when $f$ and $g$ are nonnegative on $[a, b]$, in which case the theorem states that if the graph of $f$ does not go below the graph of $g$, then the area under the graph of $f$ is at least as large as the area under the graph of $g$ (Figure 5.5.9).

► **Example 4** Evaluate

$$\int_0^1 (5 - 3\sqrt{1 - x^2})\,dx$$

***Solution.*** From parts (*a*) and (*c*) of Theorem 5.5.4 we can write

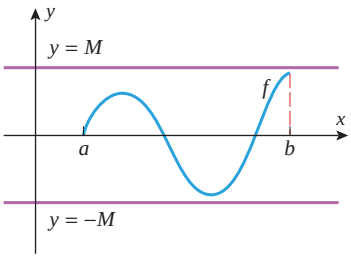
$$\int_0^1 (5 - 3\sqrt{1 - x^2})\,dx = \int_0^1 5\,dx - \int_0^1 3\sqrt{1 - x^2}\,dx = \int_0^1 5\,dx - 3\int_0^1 \sqrt{1 - x^2}\,dx$$

The first integral in this difference can be interpreted as the area of a rectangle of height 5 and base 1, so its value is 5, and from Example 1 the value of the second integral is $\pi/4$. Thus,

$$\int_0^1 (5 - 3\sqrt{1 - x^2})\,dx = 5 - 3\left(\frac{\pi}{4}\right) = 5 - \frac{3\pi}{4}$$ ◄

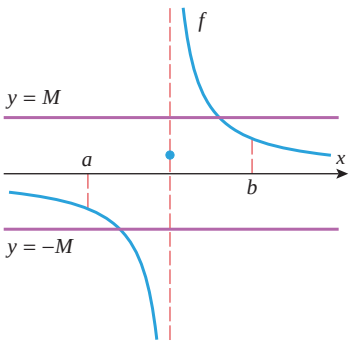
## DISCONTINUITIES AND INTEGRABILITY

In the late nineteenth and early twentieth centuries, mathematicians began to investigate conditions under which the limit that defines an integral fails to exist, that is, conditions under which a function fails to be integrable. The matter is quite complex and beyond the scope of this text. However, there are a few basic results about integrability that are important to know; we begin with a definition.



$f$ is bounded on $[a, b]$.

▲ **Figure 5.5.10**



$f$ is not bounded on $[a, b]$.

▲ **Figure 5.5.11**

**5.5.7 DEFINITION** A function $f$ that is defined on an interval is said to be ***bounded*** on the interval if there is a positive number $M$ such that

$$-M \le f(x) \le M$$

for all $x$ in the interval. Geometrically, this means that the graph of $f$ over the interval lies between the lines $y = -M$ and $y = M$.

For example, a continuous function $f$ is bounded on *every* finite closed interval because the Extreme-Value Theorem (4.4.2) implies that $f$ has an absolute maximum and an absolute minimum on the interval; hence, its graph will lie between the lines $y = -M$ and $y = M$, provided we make $M$ large enough (Figure 5.5.10). In contrast, a function that has a vertical asymptote inside of an interval is not bounded on that interval because its graph over the interval cannot be made to lie between the lines $y = -M$ and $y = M$, no matter how large we make the value of $M$ (Figure 5.5.11).

The following theorem, which we state without proof, provides some facts about integrability for functions with discontinuities. In the exercises we have included some problems that are concerned with this theorem (Exercises 42, 43, and 44).

**5.5.8 THEOREM** *Let $f$ be a function that is defined on the finite closed interval $[a, b]$.*

(*a*) *If $f$ has finitely many discontinuities in $[a, b]$ but is bounded on $[a, b]$, then $f$ is integrable on $[a, b]$.*

(*b*) *If $f$ is not bounded on $[a, b]$, then $f$ is not integrable on $[a, b]$.*

## ✔ QUICK CHECK EXERCISES 5.5 (See page 362 for answers.)

**1.** In each part, use the partition of $[2, 7]$ in the accompanying figure.

▲ **Figure Ex-1**

(a) What is $n$, the number of subintervals in this partition?

(b) $x_0 =$ _____; $x_1 =$ _____; $x_2 =$ _____; $x_3 =$ _____; $x_4 =$ _____

(c) $\Delta x_1 =$ _____; $\Delta x_2 =$ _____; $\Delta x_3 =$ _____; $\Delta x_4 =$ _____

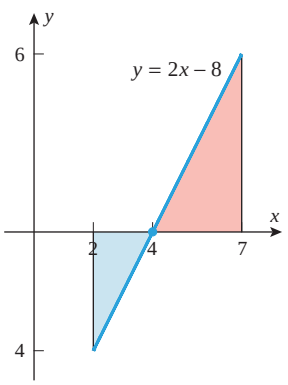
(d) The mesh of this partition is _____.

**2.** Let $f(x) = 2x - 8$. Use the partition of $[2, 7]$ in Quick Check Exercise 1 and the choices $x_1^* = 2$, $x_2^* = 4$, $x_3^* = 5$, and $x_4^* = 7$ to evaluate the Riemann sum

$$\sum_{k=1}^{4} f(x_k^*)\Delta x_k$$

**3.** Use the accompanying figure to evaluate

$$\int_2^7 (2x - 8)\,dx$$



◀ **Figure Ex-3**

**4.** Suppose that $g(x)$ is a function for which

$$\int_{-2}^{1} g(x)\,dx = 5 \quad \text{and} \quad \int_{1}^{2} g(x)\,dx = -2$$

Use this information to evaluate the definite integrals.

(a) $\displaystyle\int_1^2 5g(x)\,dx$ (b) $\displaystyle\int_{-2}^{2} g(x)\,dx$

(c) $\displaystyle\int_1^1 [g(x)]^2\,dx$ (d) $\displaystyle\int_2^{-2} 4g(x)\,dx$

## EXERCISE SET 5.5

**1–4** Find the value of

(a) $\displaystyle\sum_{k=1}^{n} f(x_k^*)\,\Delta x_k$ (b) $\max \Delta x_k$. ■

**1.** $f(x) = x + 1;\ a = 0, b = 4;\ n = 3;$
$\Delta x_1 = 1, \Delta x_2 = 1, \Delta x_3 = 2;$
$x_1^* = \frac{1}{3}, x_2^* = \frac{3}{2}, x_3^* = 3$

**2.** $f(x) = \cos x;\ a = 0, b = 2\pi;\ n = 4;$
$\Delta x_1 = \pi/2, \Delta x_2 = 3\pi/4, \Delta x_3 = \pi/2, \Delta x_4 = \pi/4;$
$x_1^* = \pi/4, x_2^* = \pi, x_3^* = 3\pi/2, x_4^* = 7\pi/4$

**3.** $f(x) = 4 - x^2;\ a = -3, b = 4;\ n = 4;$
$\Delta x_1 = 1, \Delta x_2 = 2, \Delta x_3 = 1, \Delta x_4 = 3;$
$x_1^* = -\frac{5}{2}, x_2^* = -1, x_3^* = \frac{1}{4}, x_4^* = 3$

**4.** $f(x) = x^3;\ a = -3, b = 3;\ n = 4;$
$\Delta x_1 = 2, \Delta x_2 = 1, \Delta x_3 = 1, \Delta x_4 = 2;$
$x_1^* = -2, x_2^* = 0, x_3^* = 0, x_4^* = 2$

**5–8** Use the given values of $a$ and $b$ to express the following limits as integrals. (Do not evaluate the integrals.) ■

**5.** $\displaystyle\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} (x_k^*)^2 \Delta x_k;\ a = -1, b = 2$

**6.** $\displaystyle\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} (x_k^*)^3 \Delta x_k;\ a = 1, b = 2$

**7.** $\displaystyle\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} 4x_k^*(1 - 3x_k^*) \Delta x_k;\ a = -3, b = 3$

**8.** $\displaystyle\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} (\sin^2 x_k^*) \Delta x_k;\ a = 0, b = \pi/2$

**9–10** Use Definition 5.5.1 to express the integrals as limits of Riemann sums. (Do not evaluate the integrals.) ■

**9.** (a) $\displaystyle\int_1^2 2x\,dx$ (b) $\displaystyle\int_0^1 \frac{x}{x+1}\,dx$

**10.** (a) $\displaystyle\int_1^2 \sqrt{x}\,dx$ (b) $\displaystyle\int_{-\pi/2}^{\pi/2} (1 + \cos x)\,dx$

**FOCUS ON CONCEPTS**

**11.** Explain informally why Theorem 5.5.4($a$) follows from Definition 5.5.1.

**12.** Explain informally why Theorem 5.5.6($a$) follows from Definition 5.5.1.

**13–16** Sketch the region whose signed area is represented by the definite integral, and evaluate the integral using an appropriate formula from geometry, where needed. ■

**13.** (a) $\displaystyle\int_0^3 x\,dx$ (b) $\displaystyle\int_{-2}^{-1} x\,dx$
(c) $\displaystyle\int_{-1}^{4} x\,dx$ (d) $\displaystyle\int_{-5}^{5} x\,dx$

**38.** $\int_{0}^{3} \sqrt{6x - x^2}\,dx$

**39–40** Evaluate the limit by expressing it as a definite integral over the interval $[a, b]$ and applying appropriate formulas from geometry. ■

**39.** $\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} (3x_k^* + 1)\Delta x_k;\ a = 0, b = 1$

**40.** $\lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} \sqrt{4 - (x_k^*)^2}\,\Delta x_k;\ a = -2, b = 2$

## FOCUS ON CONCEPTS

**41.** Let $f(x) = C$ be a constant function.

(a) Use a formula from geometry to show that

$$\int_{a}^{b} f(x)\,dx = C(b - a)$$

(b) Show that any Riemann sum for $f(x)$ over $[a, b]$ evaluates to $C(b - a)$. Use Definition 5.5.1 to show that

$$\int_{a}^{b} f(x)\,dx = C(b - a)$$

**42.** Define a function $f$ on $[0, 1]$ by

$$f(x) = \begin{cases} 1, & 0 < x \le 1 \\ 0, & x = 0 \end{cases}$$

Use Definition 5.5.1 to show that

$$\int_{0}^{1} f(x)\,dx = 1$$

**43.** It can be shown that every interval contains both rational and irrational numbers. Accepting this to be so, do you believe that the function

$$f(x) = \begin{cases} 1 & \text{if } x \text{ is rational} \\ 0 & \text{if } x \text{ is irrational} \end{cases}$$

is integrable on a closed interval $[a, b]$? Explain your reasoning.

**44.** Define the function $f$ by

$$f(x) = \begin{cases} \dfrac{1}{x}, & x \neq 0 \\ 0, & x = 0 \end{cases}$$

It follows from Theorem 5.5.8($b$) that $f$ is not integrable on the interval $[0, 1]$. Prove this to be the case by applying Definition 5.5.1. [*Hint:* Argue that no matter how small the mesh size is for a partition of $[0, 1]$, there will always be a choice of $x_1^*$ that will make the Riemann sum in Definition 5.5.1 as large as we like.]

**45.** In each part, use Theorems 5.5.2 and 5.5.8 to determine whether the function $f$ is integrable on the interval $[-1, 1]$.

(a) $f(x) = \cos x$

(b) $f(x) = \begin{cases} x/|x|, & x \neq 0 \\ 0, & x = 0 \end{cases}$

(c) $f(x) = \begin{cases} 1/x^2, & x \neq 0 \\ 0, & x = 0 \end{cases}$

(d) $f(x) = \begin{cases} \sin 1/x, & x \neq 0 \\ 0, & x = 0 \end{cases}$

**46.** **Writing** Write a short paragraph that discusses the similarities and differences between indefinite integrals and definite integrals.

**47.** **Writing** Write a paragraph that explains informally what it means for a function to be "integrable."

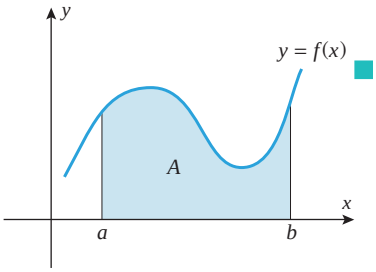
# 5.6 THE FUNDAMENTAL THEOREM OF CALCULUS

*In this section we will establish two basic relationships between definite and indefinite integrals that together constitute a result called the "Fundamental Theorem of Calculus." One part of this theorem will relate the rectangle and antiderivative methods for calculating areas, and the second part will provide a powerful method for evaluating definite integrals using antiderivatives.*



▲ **Figure 5.6.1**

## THE FUNDAMENTAL THEOREM OF CALCULUS

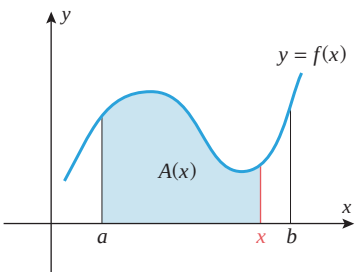
As in earlier sections, let us begin by assuming that $f$ is nonnegative and continuous on an interval $[a, b]$, in which case the area $A$ under the graph of $f$ over the interval $[a, b]$ is represented by the definite integral

$$A = \int_a^b f(x)\,dx \tag{1}$$

(Figure 5.6.1).

Recall that our discussion of the antiderivative method in Section 5.1 suggested that if $A(x)$ is the area under the graph of $f$ from $a$ to $x$ (Figure 5.6.2), then

- $A'(x) = f(x)$
- $A(a) = 0$ The area under the curve from $a$ to $a$ is the area above the single point $a$, and hence is zero.
- $A(b) = A$ The area under the curve from $a$ to $b$ is $A$.



▲ **Figure 5.6.2**

The formula $A'(x) = f(x)$ states that $A(x)$ is an antiderivative of $f(x)$, which implies that every other antiderivative of $f(x)$ on $[a, b]$ can be obtained by adding a constant to $A(x)$. Accordingly, let

$$F(x) = A(x) + C$$

be any antiderivative of $f(x)$, and consider what happens when we subtract $F(a)$ from $F(b)$:

$$F(b) - F(a) = [A(b) + C] - [A(a) + C] = A(b) - A(a) = A - 0 = A$$

Hence (1) can be expressed as

$$\int_a^b f(x)\,dx = F(b) - F(a)$$

In words, this equation states:

*The definite integral can be evaluated by finding any antiderivative of the integrand and then subtracting the value of this antiderivative at the lower limit of integration from its value at the upper limit of integration.*

Although our evidence for this result assumed that $f$ is nonnegative on $[a, b]$, this assumption is not essential.

**5.6.1 THEOREM** (*The Fundamental Theorem of Calculus, Part 1*) *If $f$ is continuous on $[a, b]$ and $F$ is any antiderivative of $f$ on $[a, b]$, then*

$$\int_a^b f(x)\,dx = F(b) - F(a) \tag{2}$$

**PROOF** Let $x_1, x_2, \ldots, x_{n-1}$ be any points in $[a, b]$ such that

$$a < x_1 < x_2 < \cdots < x_{n-1} < b$$

These values divide $[a, b]$ into $n$ subintervals

$$[a, x_1], [x_1, x_2], \ldots, [x_{n-1}, b] \tag{3}$$

whose lengths, as usual, we denote by

$$\Delta x_1, \Delta x_2, \ldots, \Delta x_n$$

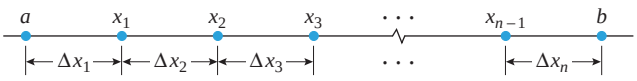
(see Figure 5.6.3). By hypothesis, $F'(x) = f(x)$ for all $x$ in $[a, b]$, so $F$ satisfies the hypotheses of the Mean-Value Theorem (4.8.2) on each subinterval in (3). Hence, we can find points $x_1^*, x_2^*, \ldots, x_n^*$ in the respective subintervals in (3) such that

$$\begin{aligned}
F(x_1) - F(a) &= F'(x_1^*)(x_1 - a) = f(x_1^*)\Delta x_1 \\
F(x_2) - F(x_1) &= F'(x_2^*)(x_2 - x_1) = f(x_2^*)\Delta x_2 \\
F(x_3) - F(x_2) &= F'(x_3^*)(x_3 - x_2) = f(x_3^*)\Delta x_3 \\
&\vdots \\
F(b) - F(x_{n-1}) &= F'(x_n^*)(b - x_{n-1}) = f(x_n^*)\Delta x_n
\end{aligned}$$

Adding the preceding equations yields

$$F(b) - F(a) = \sum_{k=1}^{n} f(x_k^*)\Delta x_k \tag{4}$$

Let us now increase $n$ in such a way that $\max \Delta x_k \to 0$. Since $f$ is assumed to be continuous, the right side of (4) approaches $\int_a^b f(x)\,dx$ by Theorem 5.5.2 and Definition 5.5.1. However,



▶ **Figure 5.6.3**

the left side of (4) is independent of $n$; that is, the left side of (4) remains constant as $n$ increases. Thus,

$$F(b) - F(a) = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k = \int_a^b f(x)\,dx \quad \blacksquare$$

It is standard to denote the difference $F(b) - F(a)$ as

$$F(x)\Big]_a^b = F(b) - F(a) \quad \text{or} \quad \big[F(x)\big]_a^b = F(b) - F(a)$$

For example, using the first of these notations we can express (2) as

$$\int_a^b f(x)\,dx = F(x)\Big]_a^b \tag{5}$$

We will sometimes write

$$F(x)\Big]_{x=a}^b = F(b) - F(a)$$

when it is important to emphasize that $a$ and $b$ are values for the variable $x$.

The integral in Example 1 represents the area of a certain trapezoid. Sketch the trapezoid, and find its area using geometry.

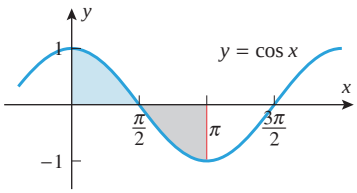
**▶ Example 1** Evaluate $\displaystyle\int_1^2 x\,dx$.

***Solution.*** The function $F(x) = \frac{1}{2}x^2$ is an antiderivative of $f(x) = x$; thus, from (2)

$$\int_1^2 x\,dx = \frac{1}{2}x^2\Big]_1^2 = \frac{1}{2}(2)^2 - \frac{1}{2}(1)^2 = 2 - \frac{1}{2} = \frac{3}{2} \quad \blacktriangleleft$$

**▶ Example 2** In Example 5 of Section 5.4 we used the definition of area to show that the area under the graph of $y = 9 - x^2$ over the interval $[0, 3]$ is 18 (square units). We can now solve that problem much more easily using the Fundamental Theorem of Calculus:

$$A = \int_0^3 (9 - x^2)\,dx = \left[9x - \frac{x^3}{3}\right]_0^3 = \left(27 - \frac{27}{3}\right) - 0 = 18 \quad \blacktriangleleft$$



▲ Figure 5.6.4

**▶ Example 3**

(a) Find the area under the curve $y = \cos x$ over the interval $[0, \pi/2]$ (Figure 5.6.4).

(b) Make a conjecture about the value of the integral

$$\int_0^{\pi} \cos x\,dx$$

and confirm your conjecture using the Fundamental Theorem of Calculus.

***Solution (a).*** Since $\cos x \geq 0$ over the interval $[0, \pi/2]$, the area $A$ under the curve is

$$A = \int_0^{\pi/2} \cos x\,dx = \sin x\Big]_0^{\pi/2} = \sin\frac{\pi}{2} - \sin 0 = 1$$

***Solution (b).*** The given integral can be interpreted as the signed area between the graph of $y = \cos x$ and the interval $[0, \pi]$. The graph in Figure 5.6.4 suggests that over the interval $[0, \pi]$ the portion of area above the $x$-axis is the same as the portion of area below the $x$-axis,

so we conjecture that the signed area is zero; this implies that the value of the integral is zero. This is confirmed by the computations

$$\int_0^{\pi} \cos x\,dx = \sin x\Big]_0^{\pi} = \sin\pi - \sin 0 = 0 \quad \blacktriangleleft$$

## THE RELATIONSHIP BETWEEN DEFINITE AND INDEFINITE INTEGRALS

Observe that in the preceding examples we did not include a constant of integration in the antiderivatives. In general, when applying the Fundamental Theorem of Calculus there is no need to include a constant of integration because it will drop out anyway. To see that this is so, let $F$ be any antiderivative of the integrand on $[a, b]$, and let $C$ be any constant; then

$$\int_a^b f(x)\,dx = \big[F(x) + C\big]_a^b = [F(b) + C] - [F(a) + C] = F(b) - F(a)$$

Thus, for purposes of evaluating a definite integral we can omit the constant of integration in

$$\int_a^b f(x)\,dx = \big[F(x) + C\big]_a^b$$

and express (5) as

$$\int_a^b f(x)\,dx = \int f(x)\,dx\Big]_a^b \tag{6}$$

which relates the definite and indefinite integrals.

### ▶ Example 4

$$\int_1^9 \sqrt{x}\,dx = \int x^{1/2}\,dx\Big]_1^9 = \frac{2}{3}x^{3/2}\Big]_1^9 = \frac{2}{3}(27 - 1) = \frac{52}{3} \quad \blacktriangleleft$$

### ▶ Example 5

Table 5.2.1 will be helpful for the following computations.

$$\int_4^9 x^2\sqrt{x}\,dx = \int_4^9 x^{5/2}\,dx = \frac{2}{7}x^{7/2}\Big]_4^9 = \frac{2}{7}(2187 - 128) = \frac{4118}{7} = 588\frac{2}{7}$$

$$\int_0^{\pi/2} \frac{\sin x}{5}\,dx = -\frac{1}{5}\cos x\Big]_0^{\pi/2} = -\frac{1}{5}\left[\cos\left(\frac{\pi}{2}\right) - \cos 0\right] = -\frac{1}{5}[0 - 1] = \frac{1}{5}$$

$$\int_0^{\pi/3} \sec^2 x\,dx = \tan x\Big]_0^{\pi/3} = \tan\left(\frac{\pi}{3}\right) - \tan 0 = \sqrt{3} - 0 = \sqrt{3}$$

$$\int_0^{\ln 3} 5e^x\,dx = 5e^x\Big]_0^{\ln 3} = 5[e^{\ln 3} - e^0] = 5[3 - 1] = 10$$

$$\int_{-e}^{-1} \frac{1}{x}\,dx = \ln|x|\Big]_{-e}^{-1} = \ln|-1| - \ln|-e| = 0 - 1 = -1$$

$$\int_{-1/2}^{1/2} \frac{1}{\sqrt{1 - x^2}}\,dx = \sin^{-1} x\Big]_{-1/2}^{1/2} = \sin^{-1}\left(\frac{1}{2}\right) - \sin^{-1}\left(-\frac{1}{2}\right) = \frac{\pi}{6} - \left(-\frac{\pi}{6}\right) = \frac{\pi}{3} \quad \blacktriangleleft$$

**TECHNOLOGY MASTERY**

If you have a CAS, read the documentation on evaluating definite integrals and then check the results in Example 5.

**WARNING** The requirements in the Fundamental Theorem of Calculus that $f$ be continuous on $[a, b]$ and that $F$ be an antiderivative for $f$ over the entire interval $[a, b]$ are important to keep in mind. Disregarding these assumptions will likely lead to incorrect results. For example, the function $f(x) = 1/x^2$ fails on two counts to be continuous at $x = 0$: $f(x)$ is not defined at $x = 0$ and $\lim_{x\to 0} f(x)$ does not exist. Thus, the Fundamental Theorem of Calculus should not be used to integrate $f$ on any interval that contains $x = 0$. However, if we ignore this and mistakenly apply Formula (2) over the interval $[-1, 1]$, we might *incorrectly* compute $\int_{-1}^{1}(1/x^2)\,dx$ by evaluating an antiderivative, $-1/x$, at the endpoints, arriving at the answer

$$-\frac{1}{x}\Big]_{-1}^{1} = -[1 - (-1)] = -2$$

But $f(x) = 1/x^2$ is a nonnegative function, so clearly a negative value for the definite integral is impossible.

The Fundamental Theorem of Calculus can be applied without modification to definite integrals in which the lower limit of integration is greater than or equal to the upper limit of integration.

**▶ Example 6**

$$\int_1^1 x^2\,dx = \frac{x^3}{3}\Big]_1^1 = \frac{1}{3} - \frac{1}{3} = 0$$

$$\int_4^0 x\,dx = \frac{x^2}{2}\Big]_4^0 = \frac{0}{2} - \frac{16}{2} = -8$$

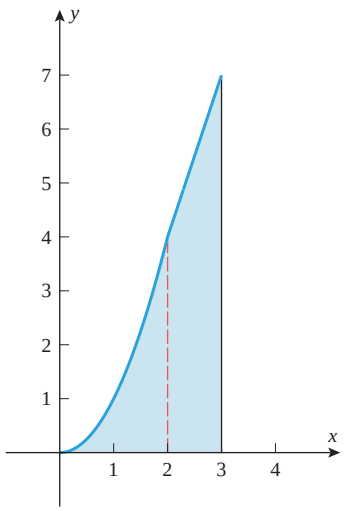
The latter result is consistent with the result that would be obtained by first reversing the limits of integration in accordance with Definition 5.5.3(b):

$$\int_4^0 x\,dx = -\int_0^4 x\,dx = -\frac{x^2}{2}\Big]_0^4 = -\left[\frac{16}{2} - \frac{0}{2}\right] = -8 \quad \blacktriangleleft$$

To integrate a continuous function that is defined piecewise on an interval $[a, b]$, split this interval into subintervals at the breakpoints of the function, and integrate separately over each subinterval in accordance with Theorem 5.5.5.

**▶ Example 7** Evaluate $\int_0^3 f(x)\,dx$ if

$$f(x) = \begin{cases} x^2, & x < 2 \\ 3x - 2, & x \geq 2 \end{cases}$$



▲ Figure 5.6.5

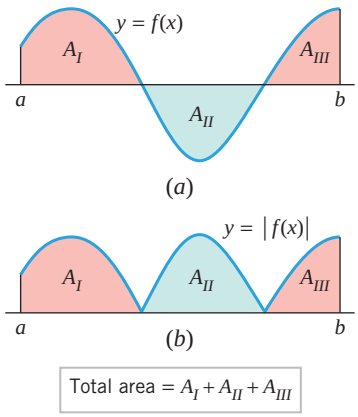
***Solution.*** See Figure 5.6.5. From Theorem 5.5.5 we can integrate from 0 to 2 and from 2 to 3 separately and add the results. This yields

$$\int_0^3 f(x)\,dx = \int_0^2 f(x)\,dx + \int_2^3 f(x)\,dx = \int_0^2 x^2\,dx + \int_2^3 (3x - 2)\,dx$$

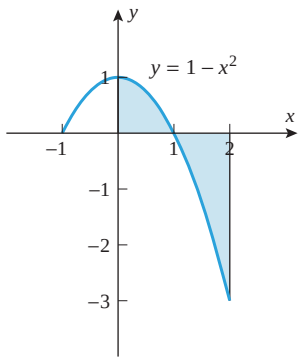
$$= \frac{x^3}{3}\Big]_0^2 + \left[\frac{3x^2}{2} - 2x\right]_2^3 = \left(\frac{8}{3} - 0\right) + \left(\frac{15}{2} - 2\right) = \frac{49}{6} \quad \blacktriangleleft$$

If $f$ is a continuous function on the interval $[a, b]$, then we define the ***total area*** between the curve $y = f(x)$ and the interval $[a, b]$ to be

$$\text{total area} = \int_a^b |f(x)|\,dx \tag{7}$$



▲ **Figure 5.6.6**



▲ **Figure 5.6.7**

(Figure 5.6.6). To compute total area using Formula (7), begin by dividing the interval of integration into subintervals on which $f(x)$ does not change sign. On the subintervals for which $0 \le f(x)$ replace $|f(x)|$ by $f(x)$, and on the subintervals for which $f(x) \le 0$ replace $|f(x)|$ by $-f(x)$. Adding the resulting integrals then yields the total area.

► **Example 8** Find the total area between the curve $y = 1 - x^2$ and the $x$-axis over the interval $[0, 2]$ (Figure 5.6.7).

***Solution.*** The area $A$ is given by

$$A = \int_0^2 |1 - x^2|\,dx = \int_0^1 (1 - x^2)\,dx + \int_1^2 -(1 - x^2)\,dx$$

$$= \left[x - \frac{x^3}{3}\right]_0^1 - \left[x - \frac{x^3}{3}\right]_1^2$$

$$= \frac{2}{3} - \left(-\frac{4}{3}\right) = 2 \quad \blacktriangleleft$$

## DUMMY VARIABLES

To evaluate a definite integral using the Fundamental Theorem of Calculus, one needs to be able to find an antiderivative of the integrand; thus, it is important to know what kinds of functions have antiderivatives. It is our next objective to show that all continuous functions have antiderivatives, but to do this we will need some preliminary results.

Formula (6) shows that there is a close relationship between the integrals

$$\int_a^b f(x)\,dx \quad \text{and} \quad \int f(x)\,dx$$

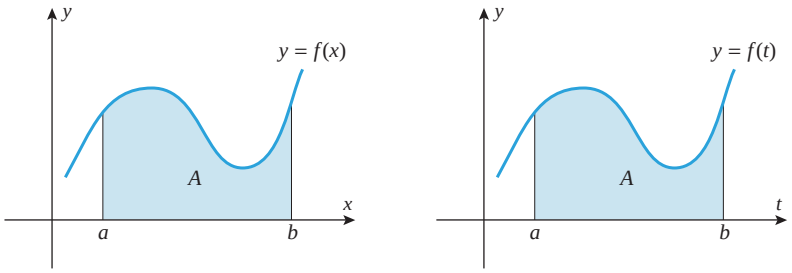
However, the definite and indefinite integrals differ in some important ways. For one thing, the two integrals are different kinds of objects—the definite integral is a *number* (the net signed area between the graph of $y = f(x)$ and the interval $[a, b]$), whereas the indefinite integral is a *function*, or more accurately a family of functions [the antiderivatives of $f(x)$]. However, the two types of integrals also differ in the role played by the variable of integration. In an indefinite integral, the variable of integration is "passed through" to the antiderivative in the sense that integrating a function of $x$ produces a function of $x$, integrating a function of $t$ produces a function of $t$, and so forth. For example,

$$\int x^2\,dx = \frac{x^3}{3} + C \quad \text{and} \quad \int t^2\,dt = \frac{t^3}{3} + C$$

In contrast, the variable of integration in a definite integral is not passed through to the end result, since the end result is a number. Thus, integrating a function of $x$ over an interval and integrating the same function of $t$ over the same interval of integration produce the same value for the integral. For example,

$$\int_1^3 x^2\,dx = \frac{x^3}{3}\Big]_{x=1}^3 = \frac{27}{3} - \frac{1}{3} = \frac{26}{3} \quad \text{and} \quad \int_1^3 t^2\,dt = \frac{t^3}{3}\Big]_{t=1}^3 = \frac{27}{3} - \frac{1}{3} = \frac{26}{3}$$

However, this latter result should not be surprising, since the area under the graph of the curve $y = f(x)$ over an interval $[a, b]$ on the $x$-axis is the same as the area under the graph of the curve $y = f(t)$ over the interval $[a, b]$ on the $t$-axis (Figure 5.6.8).



$$A = \int_a^b f(x)\,dx = \int_a^b f(t)\,dt$$

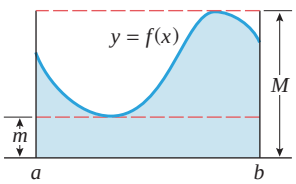
▶ Figure 5.6.8

Because the variable of integration in a definite integral plays no role in the end result, it is often referred to as a ***dummy variable***. In summary:

*Whenever you find it convenient to change the letter used for the variable of integration in a definite integral, you can do so without changing the value of the integral.*

## THE MEAN-VALUE THEOREM FOR INTEGRALS

To reach our goal of showing that continuous functions have antiderivatives, we will need to develop a basic property of definite integrals, known as the *Mean-Value Theorem for Integrals*. In Section 5.8 we will interpret this theorem using the concept of the "average value" of a continuous function over an interval. Here we will need it as a tool for developing other results.



▲ Figure 5.6.9

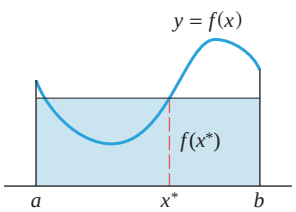
Let $f$ be a continuous nonnegative function on $[a, b]$, and let $m$ and $M$ be the minimum and maximum values of $f(x)$ on this interval. Consider the rectangles of heights $m$ and $M$ over the interval $[a, b]$ (Figure 5.6.9). It is clear geometrically from this figure that the area

$$A = \int_a^b f(x)\,dx$$

under $y = f(x)$ is at least as large as the area of the rectangle of height $m$ and no larger than the area of the rectangle of height $M$. It seems reasonable, therefore, that there is a rectangle over the interval $[a, b]$ of some appropriate height $f(x^*)$ between $m$ and $M$ whose area is precisely $A$; that is,

$$\int_a^b f(x)\,dx = f(x^*)(b - a)$$

(Figure 5.6.10). This is a special case of the following result.



The area of the shaded rectangle is equal to the area of the shaded region in Figure 5.6.9.

▲ Figure 5.6.10

**5.6.2 THEOREM** (***The Mean-Value Theorem for Integrals***) *If $f$ is continuous on a closed interval $[a, b]$, then there is at least one point $x^*$ in $[a, b]$ such that*

$$\int_a^b f(x)\,dx = f(x^*)(b - a) \tag{8}$$

**PROOF** By the Extreme-Value Theorem (4.4.2), $f$ assumes a maximum value $M$ and a minimum value $m$ on $[a, b]$. Thus, for all $x$ in $[a, b]$,

$$m \le f(x) \le M$$

and from Theorem 5.5.6($b$)

$$\int_a^b m\,dx \le \int_a^b f(x)\,dx \le \int_a^b M\,dx$$

or

$$m(b-a) \le \int_a^b f(x)\,dx \le M(b-a) \tag{9}$$

or

$$m \le \frac{1}{b-a}\int_a^b f(x)\,dx \le M$$

This implies that

$$\frac{1}{b-a}\int_a^b f(x)\,dx \tag{10}$$

is a number between $m$ and $M$, and since $f(x)$ assumes the values $m$ and $M$ on $[a, b]$, it follows from the Intermediate-Value Theorem (1.5.7) that $f(x)$ must assume the value (10) at some $x^*$ in $[a, b]$; that is,

$$\frac{1}{b-a}\int_a^b f(x)\,dx = f(x^*) \quad \text{or} \quad \int_a^b f(x)\,dx = f(x^*)(b-a) \ \blacksquare$$

▶ **Example 9** Since $f(x) = x^2$ is continuous on the interval $[1, 4]$, the Mean-Value Theorem for Integrals guarantees that there is a point $x^*$ in $[1, 4]$ such that

$$\int_1^4 x^2\,dx = f(x^*)(4-1) = (x^*)^2(4-1) = 3(x^*)^2$$

But

$$\int_1^4 x^2\,dx = \frac{x^3}{3}\Big]_1^4 = 21$$

so that

$$3(x^*)^2 = 21 \quad \text{or} \quad (x^*)^2 = 7 \quad \text{or} \quad x^* = \pm\sqrt{7}$$

Thus, $x^* = \sqrt{7} \approx 2.65$ is the point in the interval $[1, 4]$ whose existence is guaranteed by the Mean-Value Theorem for Integrals. ◀

## PART 2 OF THE FUNDAMENTAL THEOREM OF CALCULUS

In Section 5.1 we suggested that if $f$ is continuous and nonnegative on $[a, b]$, and if $A(x)$ is the area under the graph of $y = f(x)$ over the interval $[a, x]$ (Figure 5.6.2), then $A'(x) = f(x)$. But $A(x)$ can be expressed as the definite integral

$$A(x) = \int_a^x f(t)\,dt$$

(where we have used $t$ rather than $x$ as the variable of integration to avoid confusion with the $x$ that appears as the upper limit of integration). Thus, the relationship $A'(x) = f(x)$ can be expressed as

$$\frac{d}{dx}\left[\int_a^x f(t)\,dt\right] = f(x)$$

This is a special case of the following more general result, which applies even if $f$ has negative values.

**5.6.3 THEOREM** (*The Fundamental Theorem of Calculus, Part 2*) *If $f$ is continuous on an interval, then $f$ has an antiderivative on that interval. In particular, if $a$ is any point in the interval, then the function $F$ defined by*

$$F(x) = \int_a^x f(t)\,dt$$

*is an antiderivative of $f$; that is, $F'(x) = f(x)$ for each $x$ in the interval, or in an alternative notation*

$$\frac{d}{dx}\left[\int_a^x f(t)\,dt\right] = f(x) \tag{11}$$

**PROOF** We will show first that $F(x)$ is defined at each $x$ in the interval. If $x > a$ and $x$ is in the interval, then Theorem 5.5.2 applied to the interval $[a, x]$ and the continuity of $f$ ensure that $F(x)$ is defined; and if $x$ is in the interval and $x \le a$, then Definition 5.5.3 combined with Theorem 5.5.2 ensures that $F(x)$ is defined. Thus, $F(x)$ is defined for all $x$ in the interval.

Next we will show that $F'(x) = f(x)$ for each $x$ in the interval. If $x$ is not an endpoint, then it follows from the definition of a derivative that

$$\begin{aligned} F'(x) &= \lim_{h\to 0} \frac{F(x+h) - F(x)}{h} \\ &= \lim_{h\to 0} \frac{1}{h}\left[\int_a^{x+h} f(t)\,dt - \int_a^x f(t)\,dt\right] \\ &= \lim_{h\to 0} \frac{1}{h}\left[\int_a^{x+h} f(t)\,dt + \int_x^a f(t)\,dt\right] \\ &= \lim_{h\to 0} \frac{1}{h}\int_x^{x+h} f(t)\,dt \qquad \boxed{\text{Theorem 5.5.5}} \end{aligned} \tag{12}$$

Applying the Mean-Value Theorem for Integrals (5.6.2) to the integral in (12) we obtain

$$\frac{1}{h}\int_x^{x+h} f(t)\,dt = \frac{1}{h}[f(t^*)\cdot h] = f(t^*) \tag{13}$$

where $t^*$ is some number between $x$ and $x + h$. Because $t^*$ is trapped between $x$ and $x + h$, it follows that $t^* \to x$ as $h \to 0$. Thus, the continuity of $f$ at $x$ implies that $f(t^*) \to f(x)$ as $h \to 0$. Therefore, it follows from (12) and (13) that

$$F'(x) = \lim_{h\to 0}\left(\frac{1}{h}\int_x^{x+h} f(t)\,dt\right) = \lim_{h\to 0} f(t^*) = f(x)$$

If $x$ is an endpoint of the interval, then the two-sided limits in the proof must be replaced by the appropriate one-sided limits, but otherwise the arguments are identical. ■

In words, Formula (11) states:

*If a definite integral has a variable upper limit of integration, a constant lower limit of integration, and a continuous integrand, then the derivative of the integral with respect to its upper limit is equal to the integrand evaluated at the upper limit.*

▶ **Example 10** Find

$$\frac{d}{dx}\left[\int_1^x t^3\,dt\right]$$

by applying Part 2 of the Fundamental Theorem of Calculus, and then confirm the result by performing the integration and then differentiating.

***Solution.*** The integrand is a continuous function, so from (11)

$$\frac{d}{dx}\left[\int_1^x t^3\,dt\right] = x^3$$

Alternatively, evaluating the integral and then differentiating yields

$$\int_1^x t^3\,dt = \frac{t^4}{4}\Big]_{t=1}^{x} = \frac{x^4}{4} - \frac{1}{4}, \quad \frac{d}{dx}\left[\frac{x^4}{4} - \frac{1}{4}\right] = x^3$$

so the two methods for differentiating the integral agree. ◀

**▶ Example 11** Since

$$f(x) = \frac{\sin x}{x}$$

is continuous on any interval that does not contain the origin, it follows from (11) that on the interval $(0, +\infty)$ we have

$$\frac{d}{dx}\left[\int_1^x \frac{\sin t}{t}\,dt\right] = \frac{\sin x}{x}$$

Unlike the preceding example, there is no way to evaluate the integral in terms of familiar functions, so Formula (11) provides the only simple method for finding the derivative. ◀

## DIFFERENTIATION AND INTEGRATION ARE INVERSE PROCESSES

The two parts of the Fundamental Theorem of Calculus, when taken together, tell us that differentiation and integration are inverse processes in the sense that each undoes the effect of the other. To see why this is so, note that Part 1 of the Fundamental Theorem of Calculus (5.6.1) implies that

$$\int_a^x f'(t)\,dt = f(x) - f(a)$$

which tells us that if the value of $f(a)$ is known, then the function $f$ can be recovered from its derivative $f'$ by integrating. Conversely, Part 2 of the Fundamental Theorem of Calculus (5.6.3) states that

$$\frac{d}{dx}\left[\int_a^x f(t)\,dt\right] = f(x)$$

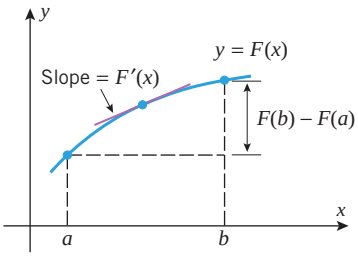
which tells us that the function $f$ can be recovered from its integral by differentiating. Thus, differentiation and integration can be viewed as inverse processes.

It is common to treat parts 1 and 2 of the Fundamental Theorem of Calculus as a single theorem and refer to it simply as the *Fundamental Theorem of Calculus*. This theorem ranks as one of the greatest discoveries in the history of science, and its formulation by Newton and Leibniz is generally regarded to be the "discovery of calculus."

## INTEGRATING RATES OF CHANGE

The Fundamental Theorem of Calculus

$$\int_a^b f(x)\,dx = F(b) - F(a) \tag{14}$$



Integrating the slope of $y = F(x)$ over the interval $[a, b]$ produces the change $F(b) - F(a)$ in the value of $F(x)$.

▲ **Figure 5.6.11**

has a useful interpretation that can be seen by rewriting it in a slightly different form. Since $F$ is an antiderivative of $f$ on the interval $[a, b]$, we can use the relationship $F'(x) = f(x)$ to rewrite (14) as

$$\int_a^b F'(x)\,dx = F(b) - F(a) \tag{15}$$

In this formula we can view $F'(x)$ as the rate of change of $F(x)$ with respect to $x$, and we can view $F(b) - F(a)$ as the *change* in the value of $F(x)$ as $x$ increases from $a$ to $b$ (Figure 5.6.11). Thus, we have the following useful principle.

**5.6.4 INTEGRATING A RATE OF CHANGE** Integrating the rate of change of $F(x)$ with respect to $x$ over an interval $[a, b]$ produces the change in the value of $F(x)$ that occurs as $x$ increases from $a$ to $b$.

Here are some examples of this idea:

- If $s(t)$ is the position of a particle in rectilinear motion, then $s'(t)$ is the instantaneous velocity of the particle at time $t$, and

$$\int_{t_1}^{t_2} s'(t)\,dt = s(t_2) - s(t_1)$$

is the displacement (or the change in the position) of the particle between the times $t_1$ and $t_2$.

- If $P(t)$ is a population (e.g., plants, animals, or people) at time $t$, then $P'(t)$ is the rate at which the population is changing at time $t$, and

$$\int_{t_1}^{t_2} P'(t)\,dt = P(t_2) - P(t_1)$$

is the change in the population between times $t_1$ and $t_2$.

- If $A(t)$ is the area of an oil spill at time $t$, then $A'(t)$ is the rate at which the area of the spill is changing at time $t$, and

$$\int_{t_1}^{t_2} A'(t)\,dt = A(t_2) - A(t_1)$$

is the change in the area of the spill between times $t_1$ and $t_2$.

- If $P'(x)$ is the marginal profit that results from producing and selling $x$ units of a product (see Section 4.5), then

$$\int_{x_1}^{x_2} P'(x)\,dx = P(x_2) - P(x_1)$$

is the change in the profit that results when the production level increases from $x_1$ units to $x_2$ units.

## ✔ QUICK CHECK EXERCISES 5.6 (See page 376 for answers.)

**1.** (a) If $F(x)$ is an antiderivative for $f(x)$, then

$$\int_a^b f(x)\,dx = _____$$

(b) $\displaystyle\int_a^b F'(x)\,dx = _____$

(c) $\displaystyle\frac{d}{dx}\left[\int_a^x f(t)\,dt\right] = _____$

**2.** (a) $\int_0^2 (3x^2 - 2x)\,dx =$ _____

(b) $\int_{-\pi}^{\pi} \cos x\,dx =$ _____

(c) $\int_0^{\frac{1}{2}\ln 5} e^x\,dx =$ _____

(d) $\int_{-1/2}^{1/2} \dfrac{1}{\sqrt{1-x^2}}\,dx =$ _____

**3.** For the function $f(x) = 3x^2 - 2x$ and an interval $[a, b]$, the point $x^*$ guaranteed by the Mean-Value Theorem for Integrals is $x^* = \frac{2}{3}$. It follows that

$$\int_a^b (3x^2 - 2x)\,dx = \text{_____}$$

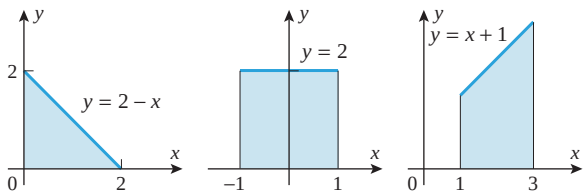
**4.** The area of an oil spill is increasing at a rate of $25t$ ft$^2$/s $t$ seconds after the spill. Between times $t = 2$ and $t = 4$ the area of the spill increases by _____ ft$^2$.

## EXERCISE SET 5.6

Graphing Utility C CAS

**1.** In each part, use a definite integral to find the area of the region, and check your answer using an appropriate formula from geometry.

(a) (b) (c)



**2.** In each part, use a definite integral to find the area under the curve $y = f(x)$ over the stated interval, and check your answer using an appropriate formula from geometry.

(a) $f(x) = x;\ [0, 5]$

(b) $f(x) = 5;\ [3, 9]$

(c) $f(x) = x + 3;\ [-1, 2]$

**3.** In each part, sketch the analogue of Figure 5.6.10 for the specified region. [Let $y = f(x)$ denote the upper boundary of the region. If $x^*$ is unique, label both it and $f(x^*)$ on your sketch. Otherwise, label $f(x^*)$ on your sketch, and determine all values of $x^*$ that satisfy Equation (8).]

(a) The region in part (a) of Exercise 1.

(b) The region in part (b) of Exercise 1.

(c) The region in part (c) of Exercise 1.

**4.** In each part, sketch the analogue of Figure 5.6.10 for the function and interval specified. [If $x^*$ is unique, label both it and $f(x^*)$ on your sketch. Otherwise, label $f(x^*)$ on your sketch, and determine all values of $x^*$ that satisfy Equation (8).]

(a) The function and interval in part (a) of Exercise 2.

(b) The function and interval in part (b) of Exercise 2.

(c) The function and interval in part (c) of Exercise 2.

**5–10** Find the area under the curve $y = f(x)$ over the stated interval. ■

**5.** $f(x) = x^3;\ [2, 3]$

**6.** $f(x) = x^4;\ [-1, 1]$

**7.** $f(x) = 3\sqrt{x};\ [1, 4]$

**8.** $f(x) = x^{-2/3};\ [1, 27]$

**9.** $f(x) = e^{2x};\ [0, \ln 2]$

**10.** $f(x) = \dfrac{1}{x};\ [1, 5]$

**11–12** Find all values of $x^*$ in the stated interval that satisfy Equation (8) in the Mean-Value Theorem for Integrals (5.6.2), and explain what these numbers represent. ■

**11.** (a) $f(x) = \sqrt{x};\ [0, 3]$

(b) $f(x) = x^2 + x;\ [-12, 0]$

**12.** (a) $f(x) = \sin x;\ [-\pi, \pi]$ (b) $f(x) = 1/x^2;\ [1, 3]$

**13–30** Evaluate the integrals using Part 1 of the Fundamental Theorem of Calculus. ■

# 5.7 RECTILINEAR MOTION REVISITED USING INTEGRATION

*In Section 4.6 we used the derivative to define the notions of instantaneous velocity and acceleration for a particle in rectilinear motion. In this section we will resume the study of such motion using the tools of integration.*

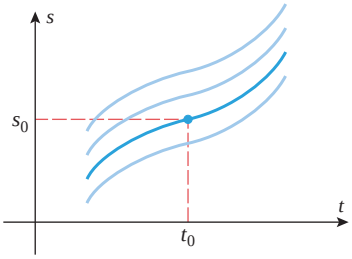
## FINDING POSITION AND VELOCITY BY INTEGRATION

Recall from Formulas (1) and (3) of Section 4.6 that if a particle in rectilinear motion has position function $s(t)$, then its instantaneous velocity and acceleration are given by the formulas

$$v(t) = s'(t) \quad \text{and} \quad a(t) = v'(t)$$

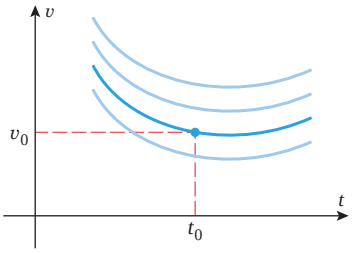
It follows from these formulas that $s(t)$ is an antiderivative of $v(t)$ and $v(t)$ is an antiderivative of $a(t)$; that is,

$$s(t) = \int v(t)\,dt \qquad \text{and} \qquad v(t) = \int a(t)\,dt \tag{1–2}$$



There is a unique position function such that $s(t_0) = s_0$.

▲ Figure 5.7.1



There is a unique velocity function such that $v(t_0) = v_0$.

▲ Figure 5.7.2

By Formula (1), if we know the velocity function $v(t)$ of a particle in rectilinear motion, then by integrating $v(t)$ we can produce a family of position functions with that velocity function. If, in addition, we know the position $s_0$ of the particle at any time $t_0$, then we have sufficient information to find the constant of integration and determine a unique position function (Figure 5.7.1). Similarly, if we know the acceleration function $a(t)$ of the particle, then by integrating $a(t)$ we can produce a family of velocity functions with that acceleration function. If, in addition, we know the velocity $v_0$ of the particle at any time $t_0$, then we have sufficient information to find the constant of integration and determine a unique velocity function (Figure 5.7.2).

▶ **Example 1** Suppose that a particle moves with velocity $v(t) = \cos \pi t$ along a coordinate line. Assuming that the particle has coordinate $s = 4$ at time $t = 0$, find its position function.

***Solution.*** The position function is

$$s(t) = \int v(t)\,dt = \int \cos \pi t\,dt = \frac{1}{\pi} \sin \pi t + C$$

Since $s = 4$ when $t = 0$, it follows that

$$4 = s(0) = \frac{1}{\pi} \sin 0 + C = C$$

Thus,

$$s(t) = \frac{1}{\pi} \sin \pi t + 4 \quad \blacktriangleleft$$

## COMPUTING DISPLACEMENT AND DISTANCE TRAVELED BY INTEGRATION

Recall that the displacement over a time interval of a particle in rectilinear motion is its final coordinate minus its initial coordinate. Thus, if the position function of the particle is $s(t)$,

then its displacement (or change in position) over the time interval $[t_0, t_1]$ is $s(t_1) - s(t_0)$. This can be written in integral form as

$$\begin{bmatrix}\text{displacement}\\ \text{over the time}\\ \text{interval } [t_0, t_1]\end{bmatrix} = \int_{t_0}^{t_1} v(t)\,dt = \int_{t_0}^{t_1} s'(t)\,dt = s(t_1) - s(t_0) \tag{3}$$

Recall that Formula (3) is a special case of the formula

$$\int_a^b F'(x)\,dx = F(b) - F(a)$$

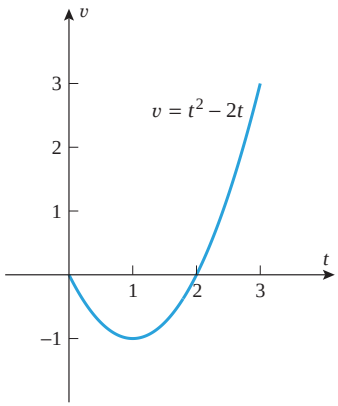
for integrating a rate of change.

In contrast, to find the distance traveled by the particle over the time interval $[t_0, t_1]$ (distance traveled in the positive direction plus the distance traveled in the negative direction), we must integrate the absolute value of the velocity function; that is,

$$\begin{bmatrix}\text{distance traveled}\\ \text{during time}\\ \text{interval } [t_0, t_1]\end{bmatrix} = \int_{t_0}^{t_1} |v(t)|\,dt \tag{4}$$

Since the absolute value of velocity is speed, Formulas (3) and (4) can be summarized informally as follows:

*Integrating velocity over a time interval produces displacement, and integrating speed over a time interval produces distance traveled.*



▲ Figure 5.7.3

**▶ Example 2** Suppose that a particle moves on a coordinate line so that its velocity at time $t$ is $v(t) = t^2 - 2t$ m/s (Figure 5.7.3).

(a) Find the displacement of the particle during the time interval $0 \le t \le 3$.

(b) Find the distance traveled by the particle during the time interval $0 \le t \le 3$.

***Solution (a).*** From (3) the displacement is

$$\int_0^3 v(t)\,dt = \int_0^3 (t^2 - 2t)\,dt = \left[\frac{t^3}{3} - t^2\right]_0^3 = 0$$

Thus, the particle is at the same position at time $t = 3$ as at $t = 0$.

***Solution (b).*** The velocity can be written as $v(t) = t^2 - 2t = t(t-2)$, from which we see that $v(t) \le 0$ for $0 \le t \le 2$ and $v(t) \ge 0$ for $2 \le t \le 3$. Thus, it follows from (4) that the distance traveled is

$$\begin{aligned}\int_0^3 |v(t)|\,dt &= \int_0^2 -v(t)\,dt + \int_2^3 v(t)\,dt\\ &= \int_0^2 -(t^2 - 2t)\,dt + \int_2^3 (t^2 - 2t)\,dt\\ &= -\left[\frac{t^3}{3} - t^2\right]_0^2 + \left[\frac{t^3}{3} - t^2\right]_2^3 = \frac{4}{3} + \frac{4}{3} = \frac{8}{3}\text{ m}\end{aligned}$$ ◀

In physical problems it is important to associate correct units with definite integrals. In general, the units for

$$\int_a^b f(x)\,dx$$

are units of $f(x)$ times units of $x$, since the integral is the limit of Riemann sums, each of whose terms has these units. For example, if $v(t)$ is in meters per second (m/s) and $t$ is in seconds (s), then

$$\int_a^b v(t)\,dt$$

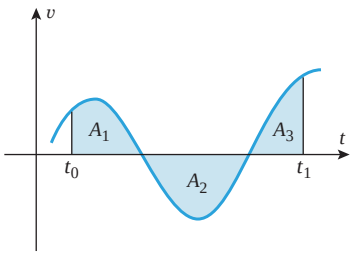
is in meters since

$$(\text{m/s}) \times \text{s} = \text{m}$$

## ANALYZING THE VELOCITY VERSUS TIME CURVE

In Section 4.6 we showed how to use the position versus time curve to obtain information about the behavior of a particle in rectilinear motion (Table 4.6.1). Similarly, there is valuable information that can be obtained from the velocity versus time curve. For example, the integral in (3) can be interpreted geometrically as the *net signed area* between the graph

of $v(t)$ and the interval $[t_0, t_1]$, and the integral in (4) can be interpreted as the *total area* between the graph of $v(t)$ and the interval $[t_0, t_1]$. Thus we have the following result.



$A_1 - A_2 + A_3$ = displacement
$A_1 + A_2 + A_3$ = distance traveled

▲ **Figure 5.7.4**

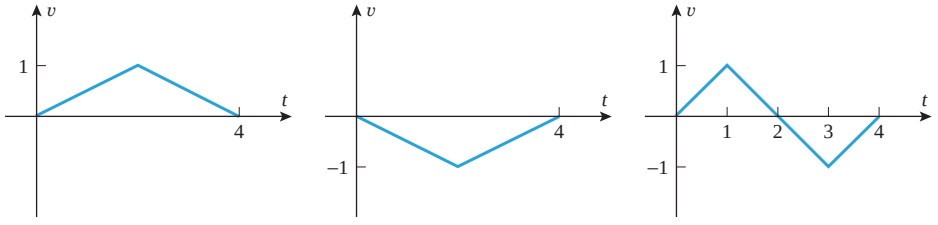
**5.7.1 FINDING DISPLACEMENT AND DISTANCE TRAVELED FROM THE VELOCITY VERSUS TIME CURVE** For a particle in rectilinear motion, the net signed area between the velocity versus time curve and the interval $[t_0, t_1]$ on the $t$-axis represents the displacement of the particle over that time interval, and the total area between the velocity versus time curve and the interval $[t_0, t_1]$ on the $t$-axis represents the distance traveled by the particle over that time interval (Figure 5.7.4).

▶ **Example 3** Figure 5.7.5 shows three velocity versus time curves for a particle in rectilinear motion along a horizontal line with the positive direction to the right. In each case find the displacement and the distance traveled over the time interval $0 \le t \le 4$, and explain what that information tells you about the motion of the particle.

***Solution (a).*** In part $(a)$ of the figure the area and the net signed area over the interval are both 2. Thus, at the end of the time period the particle is 2 units to the right of its starting point and has traveled a distance of 2 units.

***Solution (b).*** In part $(b)$ of the figure the net signed area is $-2$, and the total area is 2. Thus, at the end of the time period the particle is 2 units to the left of its starting point and has traveled a distance of 2 units.

***Solution (c).*** In part $(c)$ of the figure the net signed area is 0, and the total area is 2. Thus, at the end of the time period the particle is back at its starting point and has traveled a distance of 2 units. More specifically, it traveled 1 unit to the right over the time interval $0 \le t \le 1$ and then 1 unit to the left over the time interval $1 \le t \le 2$ (why?). ◀



▲ **Figure 5.7.5**

## CONSTANT ACCELERATION

One of the most important cases of rectilinear motion occurs when a particle has ***constant acceleration***. We will show that if a particle moves with constant acceleration along an $s$-axis, and if the position and velocity of the particle are known at some point in time, say when $t = 0$, then it is possible to derive formulas for the position $s(t)$ and the velocity $v(t)$ at any time $t$. To see how this can be done, suppose that the particle has constant acceleration

$$a(t) = a \tag{5}$$

and

$$s = s_0 \quad \text{when} \quad t = 0 \tag{6}$$
$$v = v_0 \quad \text{when} \quad t = 0 \tag{7}$$

where $s_0$ and $v_0$ are known. We call (6) and (7) the ***initial conditions***.

With (5) as a starting point, we can integrate $a(t)$ to obtain $v(t)$, and we can integrate $v(t)$ to obtain $s(t)$, using an initial condition in each case to determine the constant of integration. The computations are as follows:

$$v(t) = \int a(t)\,dt = \int a\,dt = at + C_1 \tag{8}$$

To determine the constant of integration $C_1$ we apply initial condition (7) to this equation to obtain

$$v_0 = v(0) = a \cdot 0 + C_1 = C_1$$

Substituting this in (8) and putting the constant term first yields

$$v(t) = v_0 + at$$

Since $v_0$ is constant, it follows that

$$s(t) = \int v(t)\,dt = \int (v_0 + at)\,dt = v_0 t + \tfrac{1}{2}at^2 + C_2 \tag{9}$$

To determine the constant $C_2$ we apply initial condition (6) to this equation to obtain

$$s_0 = s(0) = v_0 \cdot 0 + \tfrac{1}{2}a \cdot 0 + C_2 = C_2$$

Substituting this in (9) and putting the constant term first yields

$$s(t) = s_0 + v_0 t + \tfrac{1}{2}at^2$$

In summary, we have the following result.

**5.7.2 CONSTANT ACCELERATION** If a particle moves with constant acceleration $a$ along an $s$-axis, and if the position and velocity at time $t = 0$ are $s_0$ and $v_0$, respectively, then the position and velocity functions of the particle are

$$s(t) = s_0 + v_0 t + \tfrac{1}{2}at^2 \tag{10}$$

$$v(t) = v_0 + at \tag{11}$$

How can you tell from the graph of the velocity versus time curve whether a particle moving along a line has constant acceleration?

▶ **Example 4** Suppose that an intergalactic spacecraft uses a sail and the "solar wind" to produce a constant acceleration of $0.032\ \text{m/s}^2$. Assuming that the spacecraft has a velocity of 10,000 m/s when the sail is first raised, how far will the spacecraft travel in 1 hour, and what will its velocity be at the end of this hour?

***Solution.*** In this problem the choice of a coordinate axis is at our discretion, so we will choose it to make the computations as simple as possible. Accordingly, let us introduce an $s$-axis whose positive direction is in the direction of motion, and let us take the origin to coincide with the position of the spacecraft at the time $t = 0$ when the sail is raised. Thus, Formulas (10) and (11) apply with

$$s_0 = s(0) = 0, \quad v_0 = v(0) = 10{,}000, \quad \text{and} \quad a = 0.032$$

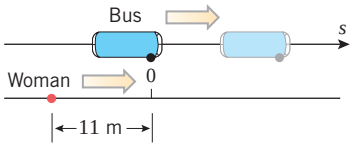
Since 1 hour corresponds to $t = 3600$ s, it follows from (10) that in 1 hour the spacecraft travels a distance of

$$s(3600) = 10{,}000(3600) + \tfrac{1}{2}(0.032)(3600)^2 \approx 36{,}200{,}000\ \text{m}$$

and it follows from (11) that after 1 hour its velocity is

$$v(3600) = 10{,}000 + (0.032)(3600) \approx 10{,}100\ \text{m/s}$$ ◀

▶ **Example 5** A bus has stopped to pick up riders, and a woman is running at a constant velocity of 5 m/s to catch it. When she is 11 m behind the front door the bus pulls away with a constant acceleration of 1 m/s$^2$. From that point in time, how long will it take for the woman to reach the front door of the bus if she keeps running with a velocity of 5 m/s?



▲ **Figure 5.7.6**

***Solution.*** As shown in Figure 5.7.6, choose the $s$-axis so that the bus and the woman are moving in the positive direction, and the front door of the bus is at the origin at the time $t = 0$ when the bus begins to pull away. To catch the bus at some later time $t$, the woman will have to cover a distance $s_w(t)$ that is equal to 11 m plus the distance $s_b(t)$ traveled by the bus; that is, the woman will catch the bus when

$$s_w(t) = s_b(t) + 11 \tag{12}$$

Since the woman has a constant velocity of 5 m/s, the distance she travels in $t$ seconds is $s_w(t) = 5t$. Thus, (12) can be written as

$$s_b(t) = 5t - 11 \tag{13}$$

Since the bus has a constant acceleration of $a = 1$ m/s$^2$, and since $s_0 = v_0 = 0$ at time $t = 0$ (why?), it follows from (10) that

$$s_b(t) = \tfrac{1}{2}t^2$$

Substituting this equation into (13) and reorganizing the terms yields the quadratic equation

$$\tfrac{1}{2}t^2 - 5t + 11 = 0 \quad \text{or} \quad t^2 - 10t + 22 = 0$$

Solving this equation for $t$ using the quadratic formula yields two solutions:

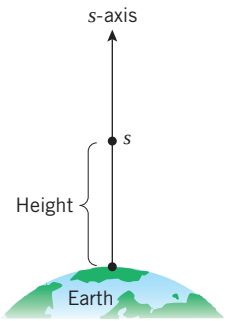
$$t = 5 - \sqrt{3} \approx 3.3 \quad \text{and} \quad t = 5 + \sqrt{3} \approx 6.7$$

(verify). Thus, the woman can reach the door at two different times, $t = 3.3$ s and $t = 6.7$ s. The reason that there are two solutions can be explained as follows: When the woman first reaches the door, she is running faster than the bus and can run past it if the driver does not see her. However, as the bus speeds up, it eventually catches up to her, and she has another chance to flag it down. ◀

## FREE-FALL MODEL

Motion that occurs when an object near the Earth is imparted some initial velocity (up or down) and thereafter moves along a vertical line is called ***free-fall motion***. In modeling free-fall motion we assume that the only force acting on the object is the Earth's gravity and that the object stays sufficiently close to the Earth that the gravitational force is constant. In particular, air resistance and the gravitational pull of other celestial bodies are neglected.

In our model we will ignore the physical size of the object by treating it as a particle, and we will assume that it moves along an $s$-axis whose origin is at the surface of the Earth and whose positive direction is up. With this convention, the $s$-coordinate of the particle is the height of the particle above the surface of the Earth (Figure 5.7.7).



▲ **Figure 5.7.7**

It is a fact of physics that a particle with free-fall motion has constant acceleration. The magnitude of this constant, denoted by the letter $g$, is called the ***acceleration due to gravity*** and is approximately 9.8 m/s$^2$ or 32 ft/s$^2$, depending on whether distance is measured in meters or feet.*

Recall that a particle is speeding up when its velocity and acceleration have the same sign and is slowing down when they have opposite signs. Thus, because we have chosen

* Strictly speaking, the constant $g$ varies with the latitude and the distance from the Earth's center. However, for motion at a fixed latitude and near the surface of the Earth, the assumption of a constant $g$ is satisfactory for many applications.

the positive direction to be up, it follows that the acceleration $a(t)$ of a particle in free fall is negative for all values of $t$. To see that this is so, observe that an upward-moving particle (positive velocity) is slowing down, so its acceleration must be negative; and a downward-moving particle (negative velocity) is speeding up, so its acceleration must also be negative. Thus, we conclude that

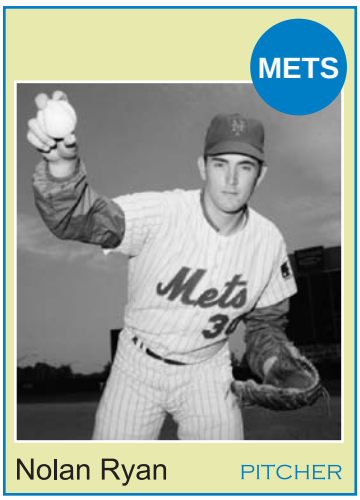
$$a(t) = -g \tag{14}$$

It now follows from this and Formulas (10) and (11) that the position and velocity functions for a particle in free-fall motion are

How would Formulas (14), (15), and (16) change if we choose the direction of the positive $s$-axis to be down?

$$s(t) = s_0 + v_0 t - \tfrac{1}{2} g t^2 \tag{15}$$

$$v(t) = v_0 - gt \tag{16}$$



Corbis.Bettmann

*Nolan Ryan as a rookie.*

▶ **Example 6** Nolan Ryan, a member of the Baseball Hall of Fame and one of the fastest baseball pitchers of all time, was able to throw a baseball 150 ft/s (over 102 mi/h). During his career, he had the opportunity to pitch in the Houston Astrodome, home to the Houston Astros Baseball Team from 1965 to 1999. The Astrodome was an indoor stadium with a ceiling 208 ft high. Could Nolan Ryan have hit the ceiling of the Astrodome if he were capable of giving a baseball an upward velocity of 100 ft/s from a height of 7 ft?

***Solution.*** Since distance is in feet, we take $g = 32$ ft/s$^2$. Initially, we have $s_0 = 7$ ft and $v_0 = 100$ ft/s, so from (15) and (16) we have

$$s(t) = 7 + 100t - 16t^2$$
$$v(t) = 100 - 32t$$

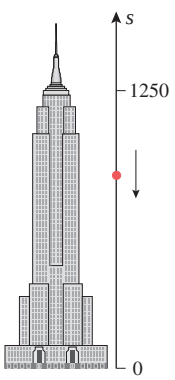
The ball will rise until $v(t) = 0$, that is, until $100 - 32t = 0$. Solving this equation we see that the ball is at its maximum height at time $t = \frac{25}{8}$. To find the height of the ball at this instant we substitute this value of $t$ into the position function to obtain

$$s\left(\tfrac{25}{8}\right) = 7 + 100\left(\tfrac{25}{8}\right) - 16\left(\tfrac{25}{8}\right)^2 = 163.25 \text{ ft}$$

which is roughly 45 ft short of hitting the ceiling. ◀

In Example 6 the ball is moving up when the velocity is positive and is moving down when the velocity is negative, so it makes sense physically that the velocity is zero when the ball reaches its peak.

▶ **Example 7** A penny is released from rest near the top of the Empire State Building at a point that is 1250 ft above the ground (Figure 5.7.8). Assuming that the free-fall model applies, how long does it take for the penny to hit the ground, and what is its speed at the time of impact?



▲ **Figure 5.7.8**

***Solution.*** Since distance is in feet, we take $g = 32$ ft/s$^2$. Initially, we have $s_0 = 1250$ and $v_0 = 0$, so from (15)

$$s(t) = 1250 - 16t^2 \tag{17}$$

Impact occurs when $s(t) = 0$. Solving this equation for $t$, we obtain

$$1250 - 16t^2 = 0$$
$$t^2 = \frac{1250}{16} = \frac{625}{8}$$
$$t = \pm\frac{25}{\sqrt{8}} \approx \pm 8.8 \text{ s}$$

Since $t \geq 0$, we can discard the negative solution and conclude that it takes $25/\sqrt{8} \approx 8.8$ s

for the penny to hit the ground. To obtain the velocity at the time of impact, we substitute $t = 25/\sqrt{8}$, $v_0 = 0$, and $g = 32$ in (16) to obtain

$$v\left(\frac{25}{\sqrt{8}}\right) = 0 - 32\left(\frac{25}{\sqrt{8}}\right) = -200\sqrt{2} \approx -282.8 \text{ ft/s}$$

Thus, the speed at the time of impact is

$$\left|v\left(\frac{25}{\sqrt{8}}\right)\right| = 200\sqrt{2} \approx 282.8 \text{ ft/s}$$

which is more than 192 mi/h. ◀

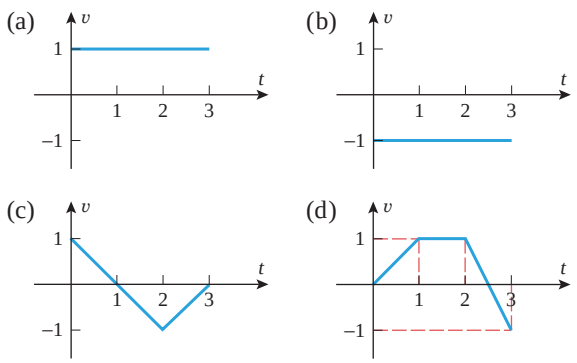
## ✔ QUICK CHECK EXERCISES 5.7 (See page 385 for answers.)

1. Suppose that a particle is moving along an $s$-axis with velocity $v(t) = 2t + 1$. If at time $t = 0$ the particle is at position $s = 2$, the position function of the particle is $s(t) =$ _____.
2. Let $v(t)$ denote the velocity function of a particle that is moving along an $s$-axis with constant acceleration $a = -2$. If $v(1) = 4$, then $v(t) =$ _____.
3. Let $v(t)$ denote the velocity function of a particle in rectilinear motion. Suppose that $v(0) = -1$, $v(3) = 2$, and the velocity versus time curve is a straight line. The displacement of the particle between times $t = 0$ and $t = 3$ is _____, and the distance traveled by the particle over this period of time is _____.
4. Based on the free-fall model, from what height must a coin be dropped so that it strikes the ground with speed 48 ft/s?

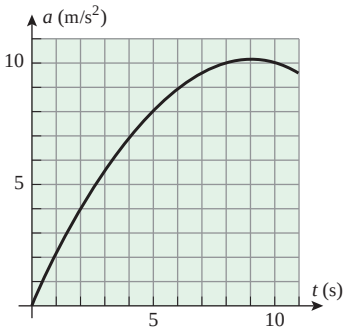
## EXERCISE SET 5.7 Graphing Utility C CAS

### FOCUS ON CONCEPTS

1. In each part, the velocity versus time curve is given for a particle moving along a line. Use the curve to find the displacement and the distance traveled by the particle over the time interval $0 \le t \le 3$.

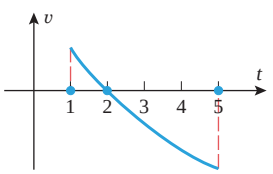


2. Given a push, a ball rolls up an inclined plane and returns to its original position after 4 s. If the total distance traveled by the ball is 16 ft, sketch a velocity versus time curve for the ball.
3. The accompanying figure shows the acceleration versus time curve for a particle moving along a coordinate line. If the initial velocity of the particle is 20 m/s, estimate
   (a) the velocity at time $t = 4$ s
   (b) the velocity at time $t = 6$ s.



◀ Figure Ex-3

4. The accompanying figure shows the velocity versus time curve over the time interval $1 \le t \le 5$ for a particle moving along a horizontal coordinate line.
   (a) What can you say about the sign of the acceleration over the time interval?
   (b) When is the particle speeding up? Slowing down?
   (c) What can you say about the location of the particle at time $t = 5$ relative to its location at time $t = 1$? Explain your reasoning.



◀ Figure Ex-4

**5–8** A particle moves along an $s$-axis. Use the given information to find the position function of the particle. ■

**5.** (a) $v(t) = 3t^2 - 2t;\ s(0) = 1$
(b) $a(t) = 3\sin 3t;\ v(0) = 3;\ s(0) = 3$

**6.** (a) $v(t) = 1 + \sin t;\ s(0) = -3$
(b) $a(t) = t^2 - 3t + 1;\ v(0) = 0;\ s(0) = 0$

**7.** (a) $v(t) = 3t + 1;\ s(2) = 4$
(b) $a(t) = t^{-2};\ v(1) = 0;\ s(1) = 2$

**8.** (a) $v(t) = t^{2/3};\ s(8) = 0$
(b) $a(t) = \sqrt{t};\ v(4) = 1;\ s(4) = -5$

**9–12** A particle moves with a velocity of $v(t)$ m/s along an $s$-axis. Find the displacement and the distance traveled by the particle during the given time interval. ■

**9.** (a) $v(t) = \sin t;\ 0 \le t \le \pi/2$
(b) $v(t) = \cos t;\ \pi/2 \le t \le 2\pi$

**10.** (a) $v(t) = 3t - 2;\ 0 \le t \le 2$
(b) $v(t) = |1 - 2t|;\ 0 \le t \le 2$

**11.** (a) $v(t) = t^3 - 3t^2 + 2t;\ 0 \le t \le 3$
(b) $v(t) = \sqrt{t} - 2;\ 0 \le t \le 3$

**12.** (a) $v(t) = t - \sqrt{t};\ 0 \le t \le 4$
(b) $v(t) = \dfrac{1}{\sqrt{t+1}};\ 0 \le t \le 3$

**13–16** A particle moves with acceleration $a(t)$ m/s$^2$ along an $s$-axis and has velocity $v_0$ m/s at time $t = 0$. Find the displacement and the distance traveled by the particle during the given time interval. ■

**13.** $a(t) = 3;\ v_0 = -1;\ 0 \le t \le 2$

**14.** $a(t) = t - 2;\ v_0 = 0;\ 1 \le t \le 5$

**15.** $a(t) = 1/\sqrt{3t+1};\ v_0 = \frac{4}{3};\ 1 \le t \le 5$

**16.** $a(t) = \sin t;\ v_0 = 1;\ \pi/4 \le t \le \pi/2$

**17.** In each part, use the given information to find the position, velocity, speed, and acceleration at time $t = 1$.
(a) $v = \sin \frac{1}{2}\pi t;\ s = 0$ when $t = 0$
(b) $a = -3t;\ s = 1$ and $v = 0$ when $t = 0$

**18.** In each part, use the given information to find the position, velocity, speed, and acceleration at time $t = 1$.
(a) $v = \cos \frac{1}{3}\pi t;\ s = 0$ when $t = \frac{3}{2}$
(b) $a = 4e^{2t-2};\ s = 1/e^2$ and $v = (2/e^2) - 3$ when $t = 0$

**19.** The velocity of an ant running along the edge of a shelf is modeled by the function

$$v(t) = \begin{cases} 5t, & 0 \le t < 1 \\ 6\sqrt{t} - \dfrac{1}{t}, & 1 \le t \le 2 \end{cases}$$

where $t$ is in seconds and $v$ is in centimeters per second. Estimate the time at which the ant is 4 cm from its starting position.

**20.** The velocity of a mouse running alongside the baseboard of a room is modeled by the function

$$v(t) = \frac{3}{t^2 + 1} - 0.5t, \quad 0 \le t \le 6$$

where $t$ is in seconds and $v$ is in meters per second. (Assume that positive values of $v$ indicate motion to the right.) Estimate the time(s) at which the mouse is 2 m from its starting position.

**21.** Suppose that the velocity function of a particle moving along an $s$-axis is $v(t) = 20t^2 - 110t + 120$ ft/s and that the particle is at the origin at time $t = 0$. Use a graphing utility to generate the graphs of $s(t)$, $v(t)$, and $a(t)$ for the first 6 s of motion.

**22.** Suppose that the acceleration function of a particle moving along an $s$-axis is $a(t) = 4t - 30$ m/s$^2$ and that the position and velocity at time $t = 0$ are $s_0 = -5$ m and $v_0 = 3$ m/s. Use a graphing utility to generate the graphs of $s(t)$, $v(t)$, and $a(t)$ for the first 25 s of motion.

**23–26 True–False** Determine whether the statement is true or false. Explain your answer. Each question refers to a particle in rectilinear motion. ■

**23.** If the particle has constant acceleration, the velocity versus time graph will be a straight line.

**24.** If the particle has constant nonzero acceleration, its position versus time curve will be a parabola.

**25.** If the total area between the velocity versus time curve and a time interval $[a, b]$ is positive, then the displacement of the particle over this time interval will be nonzero.

**26.** If $D(t)$ denotes the distance traveled by the particle over the time interval $[0, t]$, then $D(t)$ is an antiderivative for the speed of the particle.

C **27–30** For the given velocity function $v(t)$:
(a) Generate the velocity versus time curve, and use it to make a conjecture about the sign of the displacement over the given time interval.
(b) Use a CAS to find the displacement. ■

**27.** $v(t) = 0.5 - t\sin t;\ 0 \le t \le 5$

**28.** $v(t) = 0.5 - t\cos \pi t;\ 0 \le t \le 1$

**29.** $v(t) = 0.5 - te^{-t};\ 0 \le t \le 5$

**30.** $v(t) = t\ln(t + 0.1);\ 0 \le t \le 1$

**31.** Suppose that at time $t = 0$ a particle is at the origin of an $x$-axis and has a velocity of $v_0 = 25$ cm/s. For the first 4 s thereafter it has no acceleration, and then it is acted on by a retarding force that produces a constant negative acceleration of $a = -10$ cm/s$^2$.
(a) Sketch the acceleration versus time curve over the interval $0 \le t \le 12$.
(b) Sketch the velocity versus time curve over the time interval $0 \le t \le 12$.
(c) Find the $x$-coordinate of the particle at times $t = 8$ s and $t = 12$ s.

(cont.)

(d) What is the maximum $x$-coordinate of the particle over the time interval $0 \le t \le 12$?

**32–38** In these exercises assume that the object is moving with constant acceleration in the positive direction of a coordinate line, and apply Formulas (10) and (11) as appropriate. In some of these problems you will need the fact that 88 ft/s = 60 mi/h. ■

**32.** A car traveling 60 mi/h along a straight road decelerates at a constant rate of 11 ft/s$^2$.
(a) How long will it take until the speed is 45 mi/h?
(b) How far will the car travel before coming to a stop?

**33.** Spotting a police car, you hit the brakes on your new Porsche to reduce your speed from 90 mi/h to 60 mi/h at a constant rate over a distance of 200 ft.
(a) Find the acceleration in ft/s$^2$.
(b) How long does it take for you to reduce your speed to 55 mi/h?
(c) At the acceleration obtained in part (a), how long would it take for you to bring your Porsche to a complete stop from 90 mi/h?

**34.** A particle moving along a straight line is accelerating at a constant rate of 5 m/s$^2$. Find the initial velocity if the particle moves 60 m in the first 4 s.

**35.** A motorcycle, starting from rest, speeds up with a constant acceleration of 2.6 m/s$^2$. After it has traveled 120 m, it slows down with a constant acceleration of $-1.5$ m/s$^2$ until it attains a speed of 12 m/s. What is the distance traveled by the motorcycle at that point?

**36.** A sprinter in a 100 m race explodes out of the starting block with an acceleration of 4.0 m/s$^2$, which she sustains for 2.0 s. Her acceleration then drops to zero for the rest of the race.
(a) What is her time for the race?
(b) Make a graph of her distance from the starting block versus time.

**37.** A car that has stopped at a toll booth leaves the booth with a constant acceleration of 4 ft/s$^2$. At the time the car leaves the booth it is 2500 ft behind a truck traveling with a constant velocity of 50 ft/s. How long will it take for the car to catch the truck, and how far will the car be from the toll booth at that time?

**38.** In the final sprint of a rowing race the challenger is rowing at a constant speed of 12 m/s. At the point where the leader is 100 m from the finish line and the challenger is 15 m behind, the leader is rowing at 8 m/s but starts accelerating at a constant 0.5 m/s$^2$. Who wins?

**39–45** Assume that a free-fall model applies. Solve these exercises by applying Formulas (15) and (16). In these exercises take $g = 32$ ft/s$^2$ or $g = 9.8$ m/s$^2$, depending on the units. ■

**39.** A projectile is launched vertically upward from ground level with an initial velocity of 112 ft/s.
(a) Find the velocity at $t = 3$ s and $t = 5$ s.
(b) How high will the projectile rise?
(c) Find the speed of the projectile when it hits the ground.

**40.** A rock tossed downward from a height of 112 ft reaches the ground in 2 s. What is its initial velocity?

**41.** A projectile is fired vertically upward from ground level with an initial velocity of 16 ft/s.
(a) How long will it take for the projectile to hit the ground?
(b) How long will the projectile be moving upward?

**42.** In 1939, Joe Sprinz of the San Francisco Seals Baseball Club attempted to catch a ball dropped from a blimp at a height of 800 ft (for the purpose of breaking the record for catching a ball dropped from the greatest height set the preceding year by members of the Cleveland Indians).
(a) How long does it take for a ball to drop 800 ft?
(b) What is the velocity of a ball in miles per hour after an 800 ft drop (88 ft/s = 60 mi/h)?
[*Note:* As a practical matter, it is unrealistic to ignore wind resistance in this problem; however, even with the slowing effect of wind resistance, the impact of the ball slammed Sprinz's glove hand into his face, fractured his upper jaw in 12 places, broke five teeth, and knocked him unconscious. He dropped the ball!]

**43.** A model rocket is launched upward from ground level with an initial speed of 60 m/s.
(a) How long does it take for the rocket to reach its highest point?
(b) How high does the rocket go?
(c) How long does it take for the rocket to drop back to the ground from its highest point?
(d) What is the speed of the rocket when it hits the ground?

**44.** (a) Use the results in Exercise 43 to make a conjecture about the relationship between the initial and final speeds of a projectile that is launched upward from ground level and returns to ground level.
(b) Prove your conjecture.

**45.** A model rocket is fired vertically upward with an initial velocity of 49 m/s from a tower 150 m high.
(a) How long will it take for the rocket to reach its maximum height?
(b) What is the maximum height?
(c) How long will it take for the rocket to pass its starting point on the way down?
(d) What is the velocity when it passes the starting point on the way down?
(e) How long will it take for the rocket to hit the ground?
(f) What will be its speed at impact?

**46. Writing** Make a list of important features of a velocity versus time curve, and interpret each feature in terms of the motion.

**47. Writing** Use Riemann sums to argue informally that integrating speed over a time interval produces the distance traveled.

## ✔ QUICK CHECK ANSWERS 5.7

1. $t^2 + t + 2$ 2. $6 - 2t$ 3. $\frac{3}{2}; \frac{5}{2}$ 4. 36 ft

# 5.8 AVERAGE VALUE OF A FUNCTION AND ITS APPLICATIONS

*In this section we will define the notion of the "average value" of a function, and we will give various applications of this idea.*

## AVERAGE VELOCITY REVISITED

Let $s = s(t)$ denote the position function of a particle in rectilinear motion. In Section 2.1 we defined the average velocity $v_{\text{ave}}$ of the particle over the time interval $[t_0, t_1]$ to be

$$v_{\text{ave}} = \frac{s(t_1) - s(t_0)}{t_1 - t_0}$$

Let $v(t) = s'(t)$ denote the velocity function of the particle. We saw in Section 5.7 that integrating $s'(t)$ over a time interval gives the displacement of the particle over that interval. Thus,

$$\int_{t_0}^{t_1} v(t)\,dt = \int_{t_0}^{t_1} s'(t)\,dt = s(t_1) - s(t_0)$$

It follows that

$$v_{\text{ave}} = \frac{s(t_1) - s(t_0)}{t_1 - t_0} = \frac{1}{t_1 - t_0}\int_{t_0}^{t_1} v(t)\,dt \tag{1}$$

▶ **Example 1** Suppose that a particle moves along a coordinate line so that its velocity at time $t$ is $v(t) = 2 + \cos t$. Find the average velocity of the particle during the time interval $0 \le t \le \pi$.

***Solution.*** From (1) the average velocity is

$$\frac{1}{\pi - 0}\int_0^{\pi} (2 + \cos t)\,dt = \frac{1}{\pi}\left[2t + \sin t\right]_0^{\pi} = \frac{1}{\pi}(2\pi) = 2 \quad \blacktriangleleft$$

We will see that Formula (1) is a special case of a formula for what we will call the *average value* of a continuous function over a given interval.

## AVERAGE VALUE OF A CONTINUOUS FUNCTION

In scientific work, numerical information is often summarized by an *average value* or *mean value* of the observed data. There are various kinds of averages, but the most common is the ***arithmetic mean*** or ***arithmetic average***, which is formed by adding the data and dividing by the number of data points. Thus, the arithmetic average $\overline{a}$ of $n$ numbers $a_1, a_2, \ldots, a_n$ is

$$\overline{a} = \frac{1}{n}(a_1 + a_2 + \cdots + a_n) = \frac{1}{n}\sum_{k=1}^{n} a_k$$

In the case where the $a_k$'s are values of a function $f$, say,

$$a_1 = f(x_1), a_2 = f(x_2), \ldots, a_n = f(x_n)$$

then the arithmetic average $\overline{a}$ of these function values is

$$\overline{a} = \frac{1}{n}\sum_{k=1}^{n} f(x_k)$$

We will now show how to extend this concept so that we can compute not only the arithmetic average of finitely many function values but an average of *all* values of $f(x)$ as $x$ varies over a closed interval $[a, b]$. For this purpose recall the Mean-Value Theorem for Integrals (5.6.2), which states that if $f$ is continuous on the interval $[a, b]$, then there is at least one point $x^*$ in this interval such that

$$\int_a^b f(x)\,dx = f(x^*)(b-a)$$

The quantity

$$f(x^*) = \frac{1}{b-a}\int_a^b f(x)\,dx$$

will be our candidate for the average value of $f$ over the interval $[a, b]$. To explain what motivates this, divide the interval $[a, b]$ into $n$ subintervals of equal length

$$\Delta x = \frac{b-a}{n} \tag{2}$$

and choose arbitrary points $x_1^*, x_2^*, \ldots, x_n^*$ in successive subintervals. Then the arithmetic average of the values $f(x_1^*), f(x_2^*), \ldots, f(x_n^*)$ is

$$\text{ave} = \frac{1}{n}[f(x_1^*) + f(x_2^*) + \cdots + f(x_n^*)]$$

or from (2)

$$\text{ave} = \frac{1}{b-a}[f(x_1^*)\Delta x + f(x_2^*)\Delta x + \cdots + f(x_n^*)\Delta x] = \frac{1}{b-a}\sum_{k=1}^{n} f(x_k^*)\Delta x$$

Taking the limit as $n \to +\infty$ yields

$$\lim_{n\to+\infty} \frac{1}{b-a}\sum_{k=1}^{n} f(x_k^*)\Delta x = \frac{1}{b-a}\int_a^b f(x)\,dx$$

Since this equation describes what happens when we compute the average of "more and more" values of $f(x)$, we are led to the following definition.

Note that the Mean-Value Theorem for Integrals, when expressed in form (3), ensures that there is always at least one point $x^*$ in $[a, b]$ at which the value of $f$ is equal to the average value of $f$ over the interval.

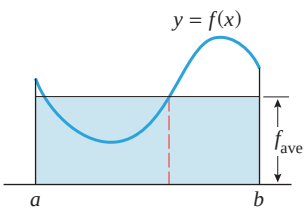
**5.8.1 DEFINITION** If $f$ is continuous on $[a, b]$, then the ***average value*** (or ***mean value***) of $f$ on $[a, b]$ is defined to be

$$f_{\text{ave}} = \frac{1}{b-a}\int_a^b f(x)\,dx \tag{3}$$

**REMARK** When $f$ is nonnegative on $[a, b]$, the quantity $f_{\text{ave}}$ has a simple geometric interpretation, which can be seen by writing (3) as

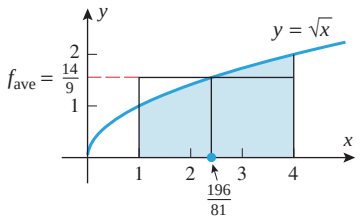
$$f_{\text{ave}} \cdot (b-a) = \int_a^b f(x)\,dx$$

The left side of this equation is the area of a rectangle with a height of $f_{\text{ave}}$ and base of length $b-a$, and the right side is the area under $y = f(x)$ over $[a, b]$. Thus, $f_{\text{ave}}$ is the height of a rectangle constructed over the interval $[a, b]$, whose area is the same as the area under the graph of $f$ over that interval (Figure 5.8.1).



▲ Figure 5.8.1

▶ **Example 2** Find the average value of the function $f(x) = \sqrt{x}$ over the interval $[1, 4]$, and find all points in the interval at which the value of $f$ is the same as the average.



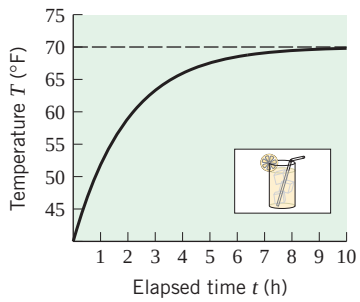
▲ Figure 5.8.2

***Solution.***

$$f_{\text{ave}} = \frac{1}{b-a}\int_a^b f(x)\,dx = \frac{1}{4-1}\int_1^4 \sqrt{x}\,dx = \frac{1}{3}\left[\frac{2x^{3/2}}{3}\right]_1^4$$

$$= \frac{1}{3}\left[\frac{16}{3} - \frac{2}{3}\right] = \frac{14}{9} \approx 1.6$$

The $x$-values at which $f(x) = \sqrt{x}$ is the same as this average satisfy $\sqrt{x} = 14/9$, from which we obtain $x = 196/81 \approx 2.4$ (Figure 5.8.2). ◀



▲ Figure 5.8.3

**▶ Example 3** A glass of lemonade with a temperature of 40°F is left to sit in a room whose temperature is a constant 70°F. Using a principle of physics called ***Newton's Law of Cooling***, one can show that if the temperature of the lemonade reaches 52°F in 1 hour, then the temperature $T$ of the lemonade as a function of the elapsed time $t$ is modeled by the equation

$$T = 70 - 30e^{-0.5t}$$

where $T$ is in degrees Fahrenheit and $t$ is in hours. The graph of this equation, shown in Figure 5.8.3, conforms to our everyday experience that the temperature of the lemonade gradually approaches the temperature of the room. Find the average temperature $T_{\text{ave}}$ of the lemonade over the first 5 hours.

In Example 3, the temperature $T$ of the lemonade rises from an initial temperature of 40°F toward the room temperature of 70°F. Explain why the formula

$$T = 70 - 30e^{-0.5t}$$

is a good model for this situation.

***Solution.*** From Definition 5.8.1 the average value of $T$ over the time interval $[0, 5]$ is

$$T_{\text{ave}} = \frac{1}{5}\int_0^5 (70 - 30e^{-0.5t})\,dt \tag{4}$$

To evaluate the definite integral, we first find the indefinite integral

$$\int (70 - 30e^{-0.5t})\,dt$$

by making the substitution

$$u = -0.5t \quad \text{so that} \quad du = -0.5\,dt \quad (\text{or } dt = -2\,du)$$

Thus,

$$\int (70 - 30e^{-0.5t})\,dt = \int (70 - 30e^{u})(-2)\,du = -2(70u - 30e^{u}) + C$$

$$= -2[70(-0.5t) - 30e^{-0.5t}] + C = 70t + 60e^{-0.5t} + C$$

and (4) can be expressed as

$$T_{\text{ave}} = \frac{1}{5}\left[70t + 60e^{-0.5t}\right]_0^5 = \frac{1}{5}\left[\left(350 + 60e^{-2.5}\right) - 60\right]$$

$$= 58 + 12e^{-2.5} \approx 59°\text{F} \quad ◀$$

## AVERAGE VALUE AND AVERAGE VELOCITY

We now have two ways to calculate the average velocity of a particle in rectilinear motion, since

$$\frac{s(t_1) - s(t_0)}{t_1 - t_0} = \frac{1}{t_1 - t_0}\int_{t_0}^{t_1} v(t)\,dt \tag{5}$$

and both of these expressions are equal to the average velocity. The left side of (5) gives the average rate of change of $s$ over $[t_0, t_1]$, while the right side gives the average value of

$v = s'$ over the interval $[t_0, t_1]$. That is, *the average velocity of the particle over the time interval $[t_0, t_1]$ is the same as the average value of the velocity function over that interval.*

Since velocity functions are generally continuous, it follows from the marginal note associated with Definition 5.8.1 that a particle's average velocity over a time interval matches the particle's velocity at some time in the interval.

▶ **Example 4** Show that if a body released from rest (initial velocity zero) is in free fall, then its average velocity over a time interval $[0, T]$ during its fall is its velocity at time $t = T/2$.

***Solution.*** It follows from Formula (16) of Section 5.7 with $v_0 = 0$ that the velocity function of the body is $v(t) = -gt$. Thus, its average velocity over a time interval $[0, T]$ is

$$\begin{aligned} v_{\text{ave}} &= \frac{1}{T-0}\int_0^T v(t)\,dt \\ &= \frac{1}{T}\int_0^T -gt\,dt \\ &= -\frac{g}{T}\left[\frac{1}{2}t^2\right]_0^T = -g\cdot\frac{T}{2} = v\left(\frac{T}{2}\right) \end{aligned}$$ ◀

The result of Example 4 can be generalized to show that the average velocity of a particle with constant acceleration during a time interval $[a, b]$ is the velocity at time $t = (a + b)/2$. (See Exercise 18.)

## ✔ QUICK CHECK EXERCISES 5.8 (See page 390 for answers.)

1. The arithmetic average of $n$ numbers, $a_1, a_2, \ldots, a_n$ is _____.
2. If $f$ is continuous on $[a, b]$, then the average value of $f$ on $[a, b]$ is _____.
3. If $f$ is continuous on $[a, b]$, then the Mean-Value Theorem for Integrals guarantees that for at least one point $x^*$ in $[a, b]$ _____ equals the average value of $f$ on $[a, b]$.
4. The average value of $f(x) = 4x^3$ on $[1, 3]$ is _____.

## EXERCISE SET 5.8 C CAS

1. (a) Find $f_{\text{ave}}$ of $f(x) = 2x$ over $[0, 4]$.
   (b) Find a point $x^*$ in $[0, 4]$ such that $f(x^*) = f_{\text{ave}}$.
   (c) Sketch a graph of $f(x) = 2x$ over $[0, 4]$, and construct a rectangle over the interval whose area is the same as the area under the graph of $f$ over the interval.
2. (a) Find $f_{\text{ave}}$ of $f(x) = x^2$ over $[0, 2]$.
   (b) Find a point $x^*$ in $[0, 2]$ such that $f(x^*) = f_{\text{ave}}$.
   (c) Sketch a graph of $f(x) = x^2$ over $[0, 2]$, and construct a rectangle over the interval whose area is the same as the area under the graph of $f$ over the interval.

**3–12** Find the average value of the function over the given interval. ■

3. $f(x) = 3x;\ [1, 3]$
4. $f(x) = \sqrt[3]{x};\ [-1, 8]$
5. $f(x) = \sin x;\ [0, \pi]$
6. $f(x) = \sec x \tan x;\ [0, \pi/3]$
7. $f(x) = 1/x;\ [1, e]$
8. $f(x) = e^x;\ [-1, \ln 5]$
9. $f(x) = \dfrac{1}{1+x^2};\ [1, \sqrt{3}]$
10. $f(x) = \dfrac{1}{\sqrt{1-x^2}};\ \left[-\frac{1}{2}, 0\right]$
11. $f(x) = e^{-2x};\ [0, 4]$
12. $f(x) = \sec^2 x;\ [-\pi/4, \pi/4]$

**FOCUS ON CONCEPTS**

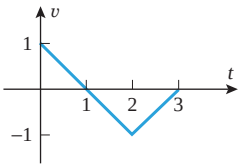
13. Let $f(x) = 3x^2$.
   (a) Find the arithmetic average of the values $f(0.4)$, $f(0.8)$, $f(1.2)$, $f(1.6)$, and $f(2.0)$.
   (b) Find the arithmetic average of the values $f(0.1)$, $f(0.2)$, $f(0.3)$, $\ldots$, $f(2.0)$.
   (c) Find the average value of $f$ on $[0, 2]$.
   (d) Explain why the answer to part (c) is less than the answers to parts (a) and (b).
14. In parts (a)–(d), let $f(x) = 1 + (1/x)$.
   (a) Find the arithmetic average of the values $f\left(\frac{6}{5}\right)$, $f\left(\frac{7}{5}\right)$, $f\left(\frac{8}{5}\right)$, $f\left(\frac{9}{5}\right)$, and $f(2)$.
   (b) Find the arithmetic average of the values $f(1.1)$, $f(1.2)$, $f(1.3)$, $\ldots$, $f(2)$.

(cont.)

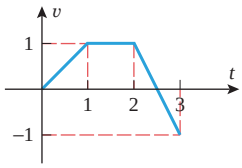
(c) Find the average value of $f$ on $[1, 2]$.
(d) Explain why the answer to part (c) is greater than the answers to parts (a) and (b).

**15.** In each part, the velocity versus time curve is given for a particle moving along a line. Use the curve to find the average velocity of the particle over the time interval $0 \le t \le 3$.

(a)



(b)



**16.** Suppose that a particle moving along a line starts from rest and has an average velocity of 2 ft/s over the time interval $0 \le t \le 5$. Sketch a velocity versus time curve for the particle assuming that the particle is also at rest at time $t = 5$. Explain how your curve satisfies the required properties.

**17.** Suppose that $f$ is a linear function. Using the graph of $f$, explain why the average value of $f$ on $[a, b]$ is

$$f\left(\frac{a+b}{2}\right)$$

**18.** Suppose that a particle moves along a coordinate line with constant acceleration. Show that the average velocity of the particle during a time interval $[a, b]$ matches the velocity of the particle at the midpoint of the interval.

**19–22 True–False** Determine whether the statement is true or false. Explain your answer. (Assume that $f$ and $g$ denote continuous functions on an interval $[a, b]$ and that $f_{\text{ave}}$ and $g_{\text{ave}}$ denote the respective average values of $f$ and $g$ on $[a, b]$.) ■

**19.** If $g_{\text{ave}} < f_{\text{ave}}$, then $g(x) \le f(x)$ on $[a, b]$.

**20.** The average value of a constant multiple of $f$ is the same multiple of $f_{\text{ave}}$; that is, if $c$ is any constant,

$$(c \cdot f)_{\text{ave}} = c \cdot f_{\text{ave}}$$

**21.** The average of the sum of two functions on an interval is the sum of the average values of the two functions on the interval; that is,

$$(f + g)_{\text{ave}} = f_{\text{ave}} + g_{\text{ave}}$$

**22.** The average of the product of two functions on an interval is the product of the average values of the two functions on the interval; that is,

$$(f \cdot g)_{\text{ave}} = f_{\text{ave}} \cdot g_{\text{ave}}$$

**23.** (a) Suppose that the velocity function of a particle moving along a coordinate line is $v(t) = 3t^3 + 2$. Find the average velocity of the particle over the time interval $1 \le t \le 4$ by integrating.

(b) Suppose that the position function of a particle moving along a coordinate line is $s(t) = 6t^2 + t$. Find the average velocity of the particle over the time interval $1 \le t \le 4$ algebraically.

**24.** (a) Suppose that the acceleration function of a particle moving along a coordinate line is $a(t) = t + 1$. Find the average acceleration of the particle over the time interval $0 \le t \le 5$ by integrating.
(b) Suppose that the velocity function of a particle moving along a coordinate line is $v(t) = \cos t$. Find the average acceleration of the particle over the time interval $0 \le t \le \pi/4$ algebraically.

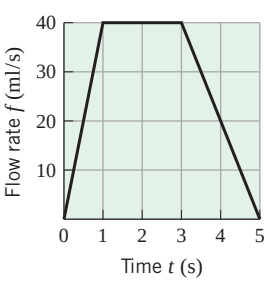
**25.** Water is run at a constant rate of 1 $\text{ft}^3/\text{min}$ to fill a cylindrical tank of radius 3 ft and height 5 ft. Assuming that the tank is initially empty, make a conjecture about the average weight of the water in the tank over the time period required to fill it, and then check your conjecture by integrating. [Take the weight density of water to be 62.4 $\text{lb}/\text{ft}^3$.]

**26.** (a) The temperature of a 10 m long metal bar is 15°C at one end and 30°C at the other end. Assuming that the temperature increases linearly from the cooler end to the hotter end, what is the average temperature of the bar?
(b) Explain why there must be a point on the bar where the temperature is the same as the average, and find it.

**27.** A traffic engineer monitors the rate at which cars enter the main highway during the afternoon rush hour. From her data she estimates that between 4:30 P.M. and 5:30 P.M. the rate $R(t)$ at which cars enter the highway is given by the formula $R(t) = 100(1 - 0.0001t^2)$ cars per minute, where $t$ is the time (in minutes) since 4:30 P.M. Find the average rate, in cars per minute, at which cars enter the highway during the first half hour of rush hour.

**28.** Suppose that the value of a yacht in dollars after $t$ years of use is $V(t) = 275{,}000e^{-0.17t}$. What is the average value of the yacht over its first 10 years of use?

**29.** A large juice glass containing 60 ml of orange juice is replenished by a server. The accompanying figure shows the rate at which orange juice is poured into the glass in milliliters per second (ml/s). Show that the average rate of change of the volume of juice in the glass during these 5 s is equal to the average value of the rate of flow of juice into the glass.



◀ **Figure Ex-29**

C **30.** The function $J_0$ defined by

$$J_0(x) = \frac{1}{\pi}\int_0^{\pi} \cos(x \sin t)\, dt$$

is called the ***Bessel function of order zero***.

(a) Find a function $f$ and an interval $[a, b]$ for which $J_0(1)$ is the average value of $f$ over $[a, b]$.

(b) Estimate $J_0(1)$.

(c) Use a CAS to graph the equation $y = J_0(x)$ over the interval $0 \le x \le 8$.

(d) Estimate the smallest positive zero of $J_0$.

**31.** Find a positive value of $k$ such that the average value of $f(x) = \sqrt{3x}$ over the interval $[0, k]$ is 6.

**32.** Suppose that a tumor grows at the rate of $r(t) = kt$ grams per week for some positive constant $k$, where $t$ is the number of weeks since the tumor appeared. When, during the second 26 weeks of growth, is the mass of the tumor the same as its average mass during that period?

**33.** **Writing** Consider the following statement: *The average value of the rate of change of a function over an interval is equal to the average rate of change of the function over that interval.* Write a short paragraph that explains why this statement may be interpreted as a rewording of Part 1 of the Fundamental Theorem of Calculus.

**34.** **Writing** If an automobile gets an average of 25 miles per gallon of gasoline, then it is also the case that on average the automobile expends $1/25$ gallon of gasoline per mile. Interpret this statement using the concept of the average value of a function over an interval.

## ✔ QUICK CHECK ANSWERS 5.8

**1.** $\frac{1}{n}\sum_{k=1}^{n} a_k$ **2.** $\frac{1}{b-a}\int_a^b f(x)\, dx$ **3.** $f(x^*)$ **4.** 40

# 5.9 EVALUATING DEFINITE INTEGRALS BY SUBSTITUTION

*In this section we will discuss two methods for evaluating definite integrals in which a substitution is required.*

## TWO METHODS FOR MAKING SUBSTITUTIONS IN DEFINITE INTEGRALS

Recall from Section 5.3 that indefinite integrals of the form

$$\int f(g(x))g'(x)\, dx$$

can sometimes be evaluated by making the $u$-substitution

$$u = g(x), \quad du = g'(x)\, dx \tag{1}$$

which converts the integral to the form

$$\int f(u)\, du$$

To apply this method to a definite integral of the form

$$\int_a^b f(g(x))g'(x)\, dx$$

we need to account for the effect that the substitution has on the $x$-limits of integration. There are two ways of doing this.

### Method 1.

First evaluate the indefinite integral

$$\int f(g(x))g'(x)\, dx$$

by substitution, and then use the relationship

$$\int_a^b f(g(x))g'(x)\,dx = \left[\int f(g(x))g'(x)\,dx\right]_a^b$$

to evaluate the definite integral. This procedure does not require any modification of the $x$-limits of integration.

**Method 2.**

Make the substitution (1) directly in the definite integral, and then use the relationship $u = g(x)$ to replace the $x$-limits, $x = a$ and $x = b$, by corresponding $u$-limits, $u = g(a)$ and $u = g(b)$. This produces a new definite integral

$$\int_{g(a)}^{g(b)} f(u)\,du$$

that is expressed entirely in terms of $u$.

▶ **Example 1** Use the two methods above to evaluate $\displaystyle\int_0^2 x(x^2+1)^3\,dx$.

***Solution by Method 1.*** If we let

$$u = x^2 + 1 \quad \text{so that} \quad du = 2x\,dx \tag{2}$$

then we obtain

$$\int x(x^2+1)^3\,dx = \frac{1}{2}\int u^3\,du = \frac{u^4}{8} + C = \frac{(x^2+1)^4}{8} + C$$

Thus,

$$\int_0^2 x(x^2+1)^3\,dx = \left[\int x(x^2+1)^3\,dx\right]_{x=0}^2$$

$$= \left.\frac{(x^2+1)^4}{8}\right]_{x=0}^2 = \frac{625}{8} - \frac{1}{8} = 78$$

***Solution by Method 2.*** If we make the substitution $u = x^2 + 1$ in (2), then

$$\text{if} \quad x = 0, \quad u = 1$$
$$\text{if} \quad x = 2, \quad u = 5$$

Thus,

$$\int_0^2 x(x^2+1)^3\,dx = \frac{1}{2}\int_1^5 u^3\,du$$

$$= \left.\frac{u^4}{8}\right]_{u=1}^5 = \frac{625}{8} - \frac{1}{8} = 78$$

which agrees with the result obtained by Method 1. ◀

The following theorem states precise conditions under which Method 2 can be used.

**5.9.1 THEOREM** *If $g'$ is continuous on $[a, b]$ and $f$ is continuous on an interval containing the values of $g(x)$ for $a \le x \le b$, then*

$$\int_a^b f(g(x))g'(x)\,dx = \int_{g(a)}^{g(b)} f(u)\,du$$

**PROOF** Since $f$ is continuous on an interval containing the values of $g(x)$ for $a \le x \le b$, it follows that $f$ has an antiderivative $F$ on that interval. If we let $u = g(x)$, then the chain rule implies that

$$\frac{d}{dx}F(g(x)) = \frac{d}{dx}F(u) = \frac{dF}{du}\frac{du}{dx} = f(u)\frac{du}{dx} = f(g(x))g'(x)$$

for each $x$ in $[a, b]$. Thus, $F(g(x))$ is an antiderivative of $f(g(x))g'(x)$ on $[a, b]$. Therefore, by Part 1 of the Fundamental Theorem of Calculus (5.6.1)

$$\int_a^b f(g(x))g'(x)\,dx = F(g(x))\Big]_a^b = F(g(b)) - F(g(a)) = \int_{g(a)}^{g(b)} f(u)\,du \quad \blacksquare$$

The choice of methods for evaluating definite integrals by substitution is generally a matter of taste, but in the following examples we will use the second method, since the idea is new.

**▶ Example 2** Evaluate

$$\text{(a)} \int_0^{\pi/8} \sin^5 2x \cos 2x\,dx \qquad \text{(b)} \int_2^5 (2x-5)(x-3)^9\,dx$$

***Solution (a).*** Let

$$u = \sin 2x \quad \text{so that} \quad du = 2\cos 2x\,dx \quad \left(\text{or } \tfrac{1}{2}\,du = \cos 2x\,dx\right)$$

With this substitution,

$$\text{if} \quad x = 0, \quad u = \sin(0) = 0$$
$$\text{if} \quad x = \pi/8, \quad u = \sin(\pi/4) = 1/\sqrt{2}$$

so

$$\int_0^{\pi/8} \sin^5 2x \cos 2x\,dx = \frac{1}{2}\int_0^{1/\sqrt{2}} u^5\,du$$
$$= \frac{1}{2}\cdot\frac{u^6}{6}\Big]_{u=0}^{1/\sqrt{2}} = \frac{1}{2}\left[\frac{1}{6(\sqrt{2})^6} - 0\right] = \frac{1}{96}$$

***Solution (b).*** Let

$$u = x - 3 \quad \text{so that} \quad du = dx$$

This leaves a factor of $2x - 5$ unresolved in the integrand. However,

$$x = u + 3, \quad \text{so} \quad 2x - 5 = 2(u+3) - 5 = 2u + 1$$

With this substitution,

$$\text{if} \quad x = 2, \quad u = 2 - 3 = -1$$
$$\text{if} \quad x = 5, \quad u = 5 - 3 = 2$$

so

$$\int_2^5 (2x-5)(x-3)^9\,dx = \int_{-1}^2 (2u+1)u^9\,du = \int_{-1}^2 (2u^{10} + u^9)\,du$$
$$= \left[\frac{2u^{11}}{11} + \frac{u^{10}}{10}\right]_{u=-1}^2 = \left(\frac{2^{12}}{11} + \frac{2^{10}}{10}\right) - \left(-\frac{2}{11} + \frac{1}{10}\right)$$
$$= \frac{52{,}233}{110} \approx 474.8 \quad \blacktriangleleft$$

**▶ Example 3** Evaluate

$$\text{(a)}\ \int_0^{3/4} \frac{dx}{1-x} \qquad \text{(b)}\ \int_0^{\ln 3} e^x(1+e^x)^{1/2}\,dx$$

***Solution (a).*** Let

$$u = 1 - x \quad \text{so that} \quad du = -dx$$

With this substitution,

$$\text{if} \quad x = 0, \quad u = 1$$
$$\text{if} \quad x = \tfrac{3}{4}, \quad u = \tfrac{1}{4}$$

Thus,

$$\int_0^{3/4} \frac{dx}{1-x} = -\int_1^{1/4} \frac{du}{u}$$
$$= -\ln|u|\Big]_{u=1}^{1/4} = -\left[\ln\left(\frac{1}{4}\right) - \ln(1)\right] = \ln 4$$

***Solution (b).*** Make the $u$-substitution

$$u = 1 + e^x, \quad du = e^x\,dx$$

and change the $x$-limits of integration ($x = 0, x = \ln 3$) to the $u$-limits

$$u = 1 + e^0 = 2, \quad u = 1 + e^{\ln 3} = 1 + 3 = 4$$

This yields

$$\int_0^{\ln 3} e^x(1+e^x)^{1/2}\,dx = \int_2^4 u^{1/2}\,du$$
$$= \frac{2}{3}u^{3/2}\Big]_{u=2}^{4} = \frac{2}{3}[4^{3/2} - 2^{3/2}] = \frac{16 - 4\sqrt{2}}{3} \quad ◀$$

The $u$-substitution in Example 3(a) produces an integral in which the upper $u$-limit is smaller than the lower $u$-limit. Use Definition 5.5.3(b) to convert this integral to one whose lower limit is smaller than the upper limit and verify that it produces an integral with the same value as that in the example.

## ✔ QUICK CHECK EXERCISES 5.9 (See page 396 for answers.)

**1.** Assume that $g'$ is continuous on $[a, b]$ and that $f$ is continuous on an interval containing the values of $g(x)$ for $a \le x \le b$. If $F$ is an antiderivative for $f$, then

$$\int_a^b f(g(x))g'(x)\,dx = _____$$

**2.** In each part, use the substitution to replace the given integral with an integral involving the variable $u$. (Do not evaluate the integral.)

(a) $\displaystyle\int_0^2 3x^2(1+x^3)^3\,dx;\ u = 1 + x^3$

(b) $\displaystyle\int_0^2 \frac{x}{\sqrt{5-x^2}}\,dx;\ u = 5 - x^2$

(c) $\displaystyle\int_0^1 \frac{e^{\sqrt{x}}}{\sqrt{x}}\,dx;\ u = \sqrt{x}$

**3.** Evaluate the integral by making an appropriate substitution.

(a) $\displaystyle\int_{-\pi}^{0} \sin(3x - \pi)\,dx =$ _____

(b) $\displaystyle\int_2^3 \frac{x}{x^2 - 2}\,dx =$ _____

(c) $\displaystyle\int_0^{\pi/2} \sqrt[3]{\sin x}\cos x\,dx =$ _____

## EXERCISE SET 5.9 Graphing Utility C CAS

**1–4** Express the integral in terms of the variable $u$, but do not evaluate it. ■

**1.** (a) $\displaystyle\int_1^3 (2x-1)^3\,dx;\ u = 2x - 1$

(b) $\displaystyle\int_0^4 3x\sqrt{25 - x^2}\,dx;\ u = 25 - x^2$

(c) $\displaystyle\int_{-1/2}^{1/2} \cos(\pi\theta)\,d\theta;\ u = \pi\theta$

(d) $\displaystyle\int_0^1 (x+2)(x+1)^5\,dx;\ u = x + 1$

**2.** (a) $\int_{-1}^{4} (5-2x)^8\,dx;\ u = 5-2x$

(b) $\int_{-\pi/3}^{2\pi/3} \frac{\sin x}{\sqrt{2+\cos x}}\,dx;\ u = 2+\cos x$

(c) $\int_{0}^{\pi/4} \tan^2 x \sec^2 x\,dx;\ u = \tan x$

(d) $\int_{0}^{1} x^3\sqrt{x^2+3}\,dx;\ u = x^2+3$

**3.** (a) $\int_{0}^{1} e^{2x-1}\,dx;\ u = 2x-1$

(b) $\int_{e}^{e^2} \frac{\ln x}{x}\,dx;\ u = \ln x$

**4.** (a) $\int_{1}^{\sqrt{3}} \frac{\sqrt{\tan^{-1} x}}{1+x^2}\,dx;\ u = \tan^{-1} x$

(b) $\int_{1}^{\sqrt{e}} \frac{dx}{x\sqrt{1-(\ln x)^2}};\ u = \ln x$

**5–18** Evaluate the definite integral two ways: first by a $u$-substitution in the definite integral and then by a $u$-substitution in the corresponding indefinite integral. ■

**5.** $\int_{0}^{1} (2x+1)^3\,dx$

**6.** $\int_{1}^{2} (4x-2)^3\,dx$

**7.** $\int_{0}^{1} (2x-1)^3\,dx$

**8.** $\int_{1}^{2} (4-3x)^8\,dx$

**50.** $\int_{1}^{\sqrt{2}} \frac{x}{3+x^4}\,dx$

C **51.** (a) Use a CAS to find the exact value of the integral

$$\int_{0}^{\pi/6} \sin^4 x\cos^3 x\,dx$$

(b) Confirm the exact value by hand calculation. [*Hint:* Use the identity $\cos^2 x = 1-\sin^2 x$.]

C **52.** (a) Use a CAS to find the exact value of the integral

$$\int_{-\pi/4}^{\pi/4} \tan^4 x\, dx$$

(b) Confirm the exact value by hand calculation. [*Hint:* Use the identity $1 + \tan^2 x = \sec^2 x$.]

**53.** (a) Find $\int_0^1 f(3x+1)\,dx$ if $\int_1^4 f(x)\,dx = 5$.

(b) Find $\int_0^3 f(3x)\,dx$ if $\int_0^9 f(x)\,dx = 5$.

(c) Find $\int_{-2}^0 xf(x^2)\,dx$ if $\int_0^4 f(x)\,dx = 1$.

**54.** Given that $m$ and $n$ are positive integers, show that

$$\int_0^1 x^m(1-x)^n\,dx = \int_0^1 x^n(1-x)^m\,dx$$

by making a substitution. Do not attempt to evaluate the integrals.

**55.** Given that $n$ is a positive integer, show that

$$\int_0^{\pi/2} \sin^n x\,dx = \int_0^{\pi/2} \cos^n x\,dx$$

by using a trigonometric identity and making a substitution. Do not attempt to evaluate the integrals.

**56.** Given that $n$ is a positive integer, evaluate the integral

$$\int_0^1 x(1-x)^n\,dx$$

**57–60** Medication can be administered to a patient in different ways. For a given method, let $c(t)$ denote the concentration of medication in the patient's bloodstream (measured in mg/L) $t$ hours after the dose is given. Over the time interval $0 \le t \le b$, the area between the graph of $c = c(t)$ and the interval $[0, b]$ indicates the "availability" of the medication for the patient's body over that time period. Determine which method provides the greater availability over the given interval. ■

**57.** Method 1: $c(t) = 5(e^{-0.2t} - e^{-t})$,
Method 2: $c(t) = 4(e^{-0.2t} - e^{-3t})$; $[0, 4]$

**58.** Method 1: $c(t) = 5(e^{-0.2t} - e^{-t})$,

**65.** Find a positive value of $k$ such that the area under the graph of $y = e^{2x}$ over the interval $[0, k]$ is 3 square units.

**66.** Use a graphing utility to estimate the value of $k$ ($k > 0$) so that the region enclosed by $y = 1/(1 + kx^2)$, $y = 0$, $x = 0$, and $x = 2$ has an area of 0.6 square unit.

**67.** (a) Find the limit

$$\lim_{n \to +\infty} \sum_{k=1}^{n} \frac{\sin(k\pi/n)}{n}$$

by evaluating an appropriate definite integral over the interval $[0, 1]$.

(b) Check your answer to part (a) by evaluating the limit directly with a CAS.

**FOCUS ON CONCEPTS**

**68.** Let

$$I = \int_{-1}^{1} \frac{1}{1 + x^2}\, dx$$

(a) Explain why $I > 0$.

(b) Show that the substitution $x = 1/u$ results in

$$I = -\int_{-1}^{1} \frac{1}{1 + x^2}\, dx = -I$$

Thus, $2I = 0$, which implies that $I = 0$. But this contradicts part (a). What is the error?

**69.** (a) Prove that if $f$ is an odd function, then

$$\int_{-a}^{a} f(x)\, dx = 0$$

and give a geometric explanation of this result. [*Hint:* One way to prove that a quantity $q$ is zero is to show that $q = -q$.]

(b) Prove that if $f$ is an even function, then

$$\int_{-a}^{a} f(x)\, dx = 2\int_{0}^{a} f(x)\, dx$$

and give a geometric explanation of this result. [*Hint:* Split the interval of integration from $-a$ to $a$ into two parts at 0.]

**70.** Show that if $f$ and $g$ are continuous functions, then

$$\int_0^t f(t - x)g(x)\, dx = \int_0^t f(x)g(t - x)\, dx$$

**71.** (a) Let

$$I = \int_0^a \frac{f(x)}{f(x) + f(a - x)}\, dx$$

Show that $I = a/2$.

[*Hint:* Let $u = a - x$, and then note the difference between the resulting integrand and 1.]

(b) Use the result of part (a) to find

$$\int_0^3 \frac{\sqrt{x}}{\sqrt{x} + \sqrt{3 - x}}\, dx$$

(c) Use the result of part (a) to find

$$\int_0^{\pi/2} \frac{\sin x}{\sin x + \cos x}\, dx$$

**72.** Evaluate

(a) $\displaystyle\int_{-1}^{1} x\sqrt{\cos(x^2)}\, dx$

(b) $\displaystyle\int_0^{\pi} \sin^8 x \cos^5 x\, dx$.

[*Hint:* Use the substitution $u = x - (\pi/2)$.]

**73.** **Writing** The two substitution methods discussed in this section yield the same result when used to evaluate a definite integral. Write a short paragraph that carefully explains why this is the case.

**74.** **Writing** In some cases, the second method for the evaluation of definite integrals has distinct advantages over the first. Provide some illustrations, and write a short paragraph that discusses the advantages of the second method in each case. [*Hint:* To get started, consider the results in Exercises 54–56, 69, and 71.]

# 5.10 LOGARITHMIC AND OTHER FUNCTIONS DEFINED BY INTEGRALS

*In Section 0.5 we defined the natural logarithm function* $\ln x$ *to be the inverse of* $e^x$. *Although this was convenient and enabled us to deduce many properties of* $\ln x$, *the mathematical foundation was shaky in that we accepted the continuity of* $e^x$ *and of all exponential functions without proof. In this section we will show that* $\ln x$ *can be defined as a certain integral, and we will use this new definition to prove that exponential functions are continuous. This integral definition is also important in applications because it provides a way of recognizing when integrals that appear in solutions of problems can be expressed as natural logarithms.*

## THE CONNECTION BETWEEN NATURAL LOGARITHMS AND INTEGRALS

The connection between natural logarithms and integrals was made in the middle of the seventeenth century in the course of investigating areas under the curve $y = 1/t$. The problem being considered was to find values of $t_1, t_2, t_3, \ldots, t_n, \ldots$ for which the areas $A_1, A_2, A_3, \ldots, A_n, \ldots$ in Figure 5.10.1*a* would be equal. Through the combined work of Isaac Newton, the Belgian Jesuit priest Gregory of St. Vincent (1584–1667), and Gregory's student Alfons A. de Sarasa (1618–1667), it was shown that by taking the points to be

$$t_1 = e, \quad t_2 = e^2, \quad t_3 = e^3, \ldots, \quad t_n = e^n, \ldots$$

each of the areas would be 1 (Figure 5.10.1*b*). Thus, in modern integral notation

$$\int_1^{e^n} \frac{1}{t}\,dt = n$$

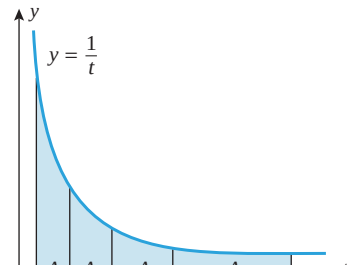
which can be expressed as

$$\int_1^{e^n} \frac{1}{t}\,dt = \ln(e^n)$$

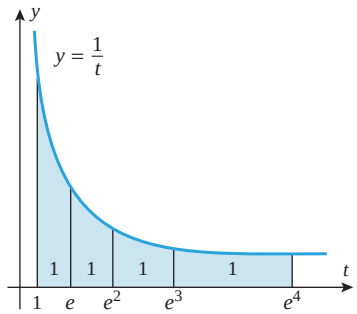
By comparing the upper limit of the integral and the expression inside the logarithm, it is a natural leap to the more general result

$$\int_1^{x} \frac{1}{t}\,dt = \ln x$$

which today we take as the formal definition of the natural logarithm.



(*a*)



(*b*)

*Not drawn to scale*

▲ **Figure 5.10.1**

**5.10.1 DEFINITION** The ***natural logarithm*** of $x$ is denoted by $\ln x$ and is defined by the integral

$$\ln x = \int_1^x \frac{1}{t}\,dt, \quad x > 0 \tag{1}$$

Review Theorem 5.5.8 and then explain why $x$ is required to be positive in Definition 5.10.1.

None of the properties of $\ln x$ obtained in this section should be new, but now, for the first time, we give them a sound mathematical footing.

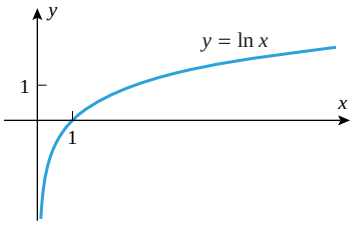
Our strategy for putting the study of logarithmic and exponential functions on a sound mathematical footing is to use (1) as a starting point and then define $e^x$ as the inverse of $\ln x$. This is the exact opposite of our previous approach in which we defined $\ln x$ to be the inverse of $e^x$. However, whereas previously we had to *assume* that $e^x$ is continuous, the continuity of $e^x$ will now follow from our definitions as a *theorem*. Our first challenge is to demonstrate that the properties of $\ln x$ resulting from Definition 5.10.1 are consistent with those obtained earlier. To start, observe that Part 2 of the Fundamental Theorem of Calculus (5.6.3) implies that $\ln x$ is differentiable and

$$\frac{d}{dx}[\ln x] = \frac{d}{dx}\left[\int_1^x \frac{1}{t}\,dt\right] = \frac{1}{x} \quad (x > 0) \tag{2}$$

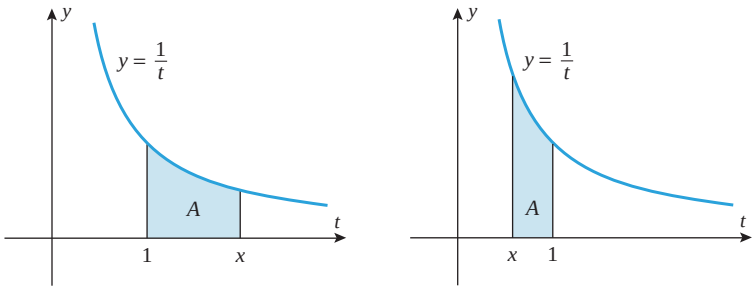
This is consistent with the derivative formula for $\ln x$ that we obtained previously. Moreover, because differentiability implies continuity, it follows that $\ln x$ is a continuous function on the interval $(0, +\infty)$.

Other properties of $\ln x$ can be obtained by interpreting the integral in (1) geometrically: In the case where $x > 1$, this integral represents the area under the curve $y = 1/t$ from $t = 1$ to $t = x$ (Figure 5.10.2*a*); in the case where $0 < x < 1$, the integral represents the negative of the area under the curve $y = 1/t$ from $t = x$ to $t = 1$ (Figure 5.10.2*b*); and in the case where $x = 1$, the integral has value 0 because its upper and lower limits of integration are the same. These geometric observations imply that

$$\begin{aligned} &\ln x > 0 \quad \text{if} \quad x > 1 \\ &\ln x < 0 \quad \text{if} \quad 0 < x < 1 \\ &\ln x = 0 \quad \text{if} \quad x = 1 \end{aligned}$$



▲ Figure 5.10.3



$$\ln x = \int_1^x \frac{1}{t}\,dt = A \qquad \ln x = \int_1^x \frac{1}{t}\,dt = -\int_x^1 \frac{1}{t}\,dt = -A$$

(a) (b)

▶ Figure 5.10.2

Also, since $1/x$ is positive for $x > 0$, it follows from (2) that $\ln x$ is an increasing function on the interval $(0, +\infty)$. This is all consistent with the graph of $\ln x$ in Figure 5.10.3.

## ALGEBRAIC PROPERTIES OF ln *x*

We can use (1) to show that Definition 5.10.1 produces the standard algebraic properties of logarithms.

**5.10.2 THEOREM** *For any positive numbers $a$ and $c$ and any rational number $r$:*

(a) $\ln ac = \ln a + \ln c$ (b) $\ln \dfrac{1}{c} = -\ln c$

(c) $\ln \dfrac{a}{c} = \ln a - \ln c$ (d) $\ln a^r = r \ln a$

**PROOF (*a*)** Treating $a$ as a constant, consider the function $f(x) = \ln(ax)$. Then

$$f'(x) = \frac{1}{ax} \cdot \frac{d}{dx}(ax) = \frac{1}{ax} \cdot a = \frac{1}{x}$$

Thus, $\ln ax$ and $\ln x$ have the same derivative on $(0, +\infty)$, so these functions must differ by a constant on this interval. That is, there is a constant $k$ such that

$$\ln ax - \ln x = k \tag{3}$$

on $(0, +\infty)$. Substituting $x = 1$ into this equation we conclude that $\ln a = k$ (verify). Thus, (3) can be written as

$$\ln ax - \ln x = \ln a$$

Setting $x = c$ establishes that

$$\ln ac - \ln c = \ln a \quad \text{or} \quad \ln ac = \ln a + \ln c$$

**PROOFS (*b*) AND (*c*)** Part $(b)$ follows immediately from part $(a)$ by substituting $1/c$ for $a$ (verify). Then

$$\ln \frac{a}{c} = \ln\left(a \cdot \frac{1}{c}\right) = \ln a + \ln \frac{1}{c} = \ln a - \ln c$$

**PROOF (*d*)** First, we will argue that part $(d)$ is satisfied if $r$ is any nonnegative integer. If $r = 1$, then $(d)$ is clearly satisfied; if $r = 0$, then $(d)$ follows from the fact that $\ln 1 = 0$. Suppose that we know $(d)$ is satisfied for $r$ equal to some integer $n$. It then follows from part $(a)$ that

$$\ln a^{n+1} = \ln[a \cdot a^n] = \ln a + \ln a^n = \ln a + n \ln a = (n+1) \ln a$$

How is the proof of Theorem 5.10.2(*d*) for the case where $r$ is a nonnegative integer analogous to a row of falling dominos? (This "domino" argument uses an informal version of a property of the integers known as the *principle of mathematical induction*.)

That is, if $(d)$ is valid for $r$ equal to some integer $n$, then it is also valid for $r = n + 1$. However, since we know $(d)$ is satisfied if $r = 1$, it follows that $(d)$ is valid for $r = 2$. But this implies that $(d)$ is satisfied for $r = 3$, which in turn implies that $(d)$ is valid for $r = 4$, and so forth. We conclude that $(d)$ is satisfied if $r$ is any nonnegative integer.

Next, suppose that $r = -m$ is a negative integer. Then

$$\begin{aligned} \ln a^r = \ln a^{-m} = \ln \frac{1}{a^m} &= -\ln a^m && \text{By part } (b) \\ &= -m \ln a && \text{Part } (d) \text{ is valid for positive powers.} \\ &= r \ln a \end{aligned}$$

which shows that $(d)$ is valid for any negative integer $r$. Combining this result with our previous conclusion that $(d)$ is satisfied for a nonnegative integer $r$ shows that $(d)$ is valid if $r$ is *any* integer.

Finally, suppose that $r = m/n$ is any rational number, where $m \neq 0$ and $n \neq 0$ are integers. Then

$$\begin{aligned} \ln a^r = \frac{n \ln a^r}{n} &= \frac{\ln[(a^r)^n]}{n} && \text{Part } (d) \text{ is valid for integer powers.} \\ &= \frac{\ln a^{rn}}{n} && \text{Property of exponents} \\ &= \frac{\ln a^m}{n} && \text{Definition of } r \\ &= \frac{m \ln a}{n} && \text{Part } (d) \text{ is valid for integer powers.} \\ &= \frac{m}{n} \ln a = r \ln a \end{aligned}$$

which shows that $(d)$ is valid for any rational number $r$. ■

## APPROXIMATING ln *x* NUMERICALLY

For specific values of $x$, the value of $\ln x$ can be approximated numerically by approximating the definite integral in (1), say by using the midpoint approximation that was discussed in Section 5.4.

**Table 5.10.1**

$n = 10$
$\Delta t = (b - a)/n = (2 - 1)/10 = 0.1$

| $k$ | $t_k^*$ | $1/t_k^*$ |
|---|---|---|
| 1 | 1.05 | 0.952381 |
| 2 | 1.15 | 0.869565 |
| 3 | 1.25 | 0.800000 |
| 4 | 1.35 | 0.740741 |
| 5 | 1.45 | 0.689655 |
| 6 | 1.55 | 0.645161 |
| 7 | 1.65 | 0.606061 |
| 8 | 1.75 | 0.571429 |
| 9 | 1.85 | 0.540541 |
| 10 | 1.95 | 0.512821 |
| | | 6.928355 |

$$\Delta t \sum_{k=1}^{n} f(t_k^*) \approx (0.1)(6.928355) \approx 0.692836$$

**▶ Example 1** Approximate $\ln 2$ using the midpoint approximation with $n = 10$.

***Solution.*** From (1), the exact value of $\ln 2$ is represented by the integral

$$\ln 2 = \int_1^2 \frac{1}{t}\, dt$$

The midpoint rule is given in Formulas (5) and (6) of Section 5.4. Expressed in terms of $t$, the latter formula is

$$\int_a^b f(t)\, dt \approx \Delta t \sum_{k=1}^{n} f(t_k^*)$$

where $\Delta t$ is the common width of the subintervals and $t_1^*, t_2^*, \ldots, t_n^*$ are the midpoints. In this case we have 10 subintervals, so $\Delta t = (2 - 1)/10 = 0.1$. The computations to six decimal places are shown in Table 5.10.1. By comparison, a calculator set to display six decimal places gives $\ln 2 \approx 0.693147$, so the magnitude of the error in the midpoint approximation is about 0.000311. Greater accuracy in the midpoint approximation can be obtained by increasing $n$. For example, the midpoint approximation with $n = 100$ yields $\ln 2 \approx 0.693144$, which is correct to five decimal places. ◀

## DOMAIN, RANGE, AND END BEHAVIOR OF ln *x*

**5.10.3 THEOREM**

(*a*) *The domain of* $\ln x$ *is* $(0, +\infty)$.

(*b*) $\lim_{x \to 0^+} \ln x = -\infty$ *and* $\lim_{x \to +\infty} \ln x = +\infty$

(*c*) *The range of* $\ln x$ *is* $(-\infty, +\infty)$.

**PROOFS (*a*) AND (*b*)** We have already shown that $\ln x$ is defined and increasing on the interval $(0, +\infty)$. To prove that $\ln x \to +\infty$ as $x \to +\infty$, we must show that given any number $M > 0$, the value of $\ln x$ exceeds $M$ for sufficiently large values of $x$. To do this, let $N$ be any integer. If $x > 2^N$, then

$$\ln x > \ln 2^N = N \ln 2 \tag{4}$$

by Theorem 5.10.2(*d*). Since

$$\ln 2 = \int_1^2 \frac{1}{t}\, dt > 0$$

it follows that $N \ln 2$ can be made arbitrarily large by choosing $N$ sufficiently large. In particular, we can choose $N$ so that $N \ln 2 > M$. It now follows from (4) that if $x > 2^N$, then $\ln x > M$, and this proves that

$$\lim_{x \to +\infty} \ln x = +\infty$$

Furthermore, by observing that $v = 1/x \to +\infty$ as $x \to 0^+$, we can use the preceding limit and Theorem 5.10.2(*b*) to conclude that

$$\lim_{x \to 0^+} \ln x = \lim_{v \to +\infty} \ln \frac{1}{v} = \lim_{v \to +\infty} (-\ln v) = -\infty$$

**PROOF (*c*)** It follows from part (*a*), the continuity of $\ln x$, and the Intermediate-Value Theorem (1.5.7) that $\ln x$ assumes every real value as $x$ varies over the interval $(0, +\infty)$ (why?). ■

## DEFINITION OF $e^x$

In Chapter 0 we defined $\ln x$ to be the inverse of the natural exponential function $e^x$. Now that we have a formal definition of $\ln x$ in terms of an integral, we will define the natural exponential function to be the inverse of $\ln x$.

Since $\ln x$ is increasing and continuous on $(0, +\infty)$ with range $(-\infty, +\infty)$, there is exactly one (positive) solution to the equation $\ln x = 1$. We *define* $e$ to be the unique solution to $\ln x = 1$, so

$$\ln e = 1 \tag{5}$$

Furthermore, if $x$ is any real number, there is a unique positive solution $y$ to $\ln y = x$, so for irrational values of $x$ we *define* $e^x$ to be this solution. That is, when $x$ is irrational, $e^x$ is defined by

$$\ln e^x = x \tag{6}$$

Note that for rational values of $x$, we also have $\ln e^x = x \ln e = x$ from Theorem 5.10.2(*d*). Moreover, it follows immediately that $e^{\ln x} = x$ for any $x > 0$. Thus, (6) defines the exponential function for all real values of $x$ as the inverse of the natural logarithm function.

**5.10.4 DEFINITION** The inverse of the natural logarithm function $\ln x$ is denoted by $e^x$ and is called the ***natural exponential function***.

We can now establish the differentiability of $e^x$ and confirm that

$$\frac{d}{dx}[e^x] = e^x$$

**5.10.5 THEOREM** *The natural exponential function $e^x$ is differentiable, and hence continuous, on $(-\infty, +\infty)$, and its derivative is*

$$\frac{d}{dx}[e^x] = e^x$$

**PROOF** Because $\ln x$ is differentiable and

$$\frac{d}{dx}[\ln x] = \frac{1}{x} > 0$$

for all $x$ in $(0, +\infty)$, it follows from Theorem 3.3.1, with $f(x) = \ln x$ and $f^{-1}(x) = e^x$, that $e^x$ is differentiable on $(-\infty, +\infty)$ and its derivative is

$$\frac{d}{dx}\underbrace{[e^x]}_{f^{-1}(x)} = \underbrace{\frac{1}{1/e^x}}_{f'(f^{-1}(x))} = e^x \quad \blacksquare$$

## IRRATIONAL EXPONENTS

Recall from Theorem 5.10.2(*d*) that if $a > 0$ and $r$ is a rational number, then $\ln a^r = r \ln a$. Then $a^r = e^{\ln a^r} = e^{r \ln a}$ for any positive value of $a$ and any rational number $r$. But the expression $e^{r \ln a}$ makes sense for *any* real number $r$, whether rational or irrational, so it is a good candidate to give meaning to $a^r$ for any real number $r$.

**5.10.6 DEFINITION** If $a > 0$ and $r$ is a real number, $a^r$ is defined by

$$a^r = e^{r \ln a} \tag{7}$$

Use Definition 5.10.6 to prove that if $a > 0$ and $r$ is a real number, then $\ln a^r = r \ln a$.

With this definition it can be shown that the standard algebraic properties of exponents, such as

$$a^p a^q = a^{p+q}, \quad \frac{a^p}{a^q} = a^{p-q}, \quad (a^p)^q = a^{pq}, \quad (a^p)(b^p) = (ab)^p$$

hold for any real values of $a$, $b$, $p$, and $q$, where $a$ and $b$ are positive. In addition, using (7) for a real exponent $r$, we can define the power function $x^r$ whose domain consists of all positive real numbers, and for a positive base $b$ we can define the ***base b exponential function $b^x$*** whose domain consists of all real numbers.

**5.10.7 THEOREM**

(*a*) *For any real number $r$, the power function $x^r$ is differentiable on $(0, +\infty)$ and its derivative is*

$$\frac{d}{dx}[x^r] = rx^{r-1}$$

(*b*) *For $b > 0$ and $b \neq 1$, the base $b$ exponential function $b^x$ is differentiable on $(-\infty, +\infty)$ and its derivative is*

$$\frac{d}{dx}[b^x] = b^x \ln b$$

**PROOF** The differentiability of $x^r = e^{r \ln x}$ and $b^x = e^{x \ln b}$ on their domains follows from the differentiability of $\ln x$ on $(0, +\infty)$ and of $e^x$ on $(-\infty, +\infty)$:

$$\frac{d}{dx}[x^r] = \frac{d}{dx}[e^{r \ln x}] = e^{r \ln x} \cdot \frac{d}{dx}[r \ln x] = x^r \cdot \frac{r}{x} = r x^{r-1}$$

$$\frac{d}{dx}[b^x] = \frac{d}{dx}[e^{x \ln b}] = e^{x \ln b} \cdot \frac{d}{dx}[x \ln b] = b^x \ln b \quad \blacksquare$$

We expressed $e$ as the value of a limit in Formulas (7) and (8) of Section 1.3 and in Formula (1) of Section 3.2. We now have the mathematical tools necessary to prove the existence of these limits.

**5.10.8 THEOREM**

$$(a) \quad \lim_{x \to 0} (1 + x)^{1/x} = e \qquad (b) \quad \lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x = e \qquad (c) \quad \lim_{x \to -\infty} \left(1 + \frac{1}{x}\right)^x = e$$

**PROOF** We will prove part $(a)$; the proofs of parts $(b)$ and $(c)$ follow from this limit and are left as exercises. We first observe that

$$\frac{d}{dx}[\ln(x + 1)]\bigg|_{x=0} = \frac{1}{x + 1} \cdot 1\bigg|_{x=0} = 1$$

However, using the definition of the derivative, we obtain

$$1 = \frac{d}{dx}[\ln(x + 1)]\bigg|_{x=0} = \lim_{h \to 0} \frac{\ln(0 + h + 1) - \ln(0 + 1)}{h}$$

$$= \lim_{h \to 0} \left[\frac{1}{h} \cdot \ln(1 + h)\right]$$

or, equivalently,

$$\lim_{x \to 0} \frac{1}{x} \cdot \ln(1 + x) = 1 \tag{8}$$

Now

$$\lim_{x \to 0} (1 + x)^{1/x} = \lim_{x \to 0} e^{(\ln(1+x))/x} \qquad \text{Definition 5.10.6}$$

$$= e^{\lim_{x \to 0}[(\ln(1+x))/x]} \qquad \text{Theorem 1.5.5}$$

$$= e^1 \qquad \text{Equation (8)}$$

$$= e \quad \blacksquare$$

## GENERAL LOGARITHMS

We note that for $b > 0$ and $b \neq 1$, the function $b^x$ is one-to-one and so has an inverse function. Using the definition of $b^x$, we can solve $y = b^x$ for $x$ as a function of $y$:

$$y = b^x = e^{x \ln b}$$

$$\ln y = \ln(e^{x \ln b}) = x \ln b$$

$$\frac{\ln y}{\ln b} = x$$

Thus, the inverse function for $b^x$ is $(\ln x)/(\ln b)$.

**5.10.9 DEFINITION** For $b > 0$ and $b \neq 1$, the ***base b logarithm*** function, denoted $\log_b x$, is defined by

$$\log_b x = \frac{\ln x}{\ln b} \tag{9}$$

It follows immediately from this definition that $\log_b x$ is the inverse function for $b^x$ and satisfies the properties in Table 0.5.3. Furthermore, $\log_b x$ is differentiable, and hence continuous, on $(0, +\infty)$, and its derivative is

$$\frac{d}{dx}[\log_b x] = \frac{1}{x \ln b}$$

As a final note of consistency, we observe that $\log_e x = \ln x$.

## FUNCTIONS DEFINED BY INTEGRALS

The functions we have dealt with thus far in this text are called ***elementary functions***; they include polynomial, rational, power, exponential, logarithmic, trigonometric, and inverse trigonometric functions, and all other functions that can be obtained from these by addition, subtraction, multiplication, division, root extraction, and composition.

However, there are many important functions that do not fall into this category. Such functions occur in many ways, but they commonly arise in the course of solving initial-value problems of the form

$$\frac{dy}{dx} = f(x), \quad y(x_0) = y_0 \tag{10}$$

Recall from Example 6 of Section 5.2 and the discussion preceding it that the basic method for solving (10) is to integrate $f(x)$, and then use the initial condition to determine the constant of integration. It can be proved that if $f$ is continuous, then (10) has a unique solution and that this procedure produces it. However, there is another approach: Instead of solving each initial-value problem individually, we can find a general formula for the solution of (10), and then apply that formula to solve specific problems. We will now show that

$$y(x) = y_0 + \int_{x_0}^{x} f(t)\,dt \tag{11}$$

is a formula for the solution of (10). To confirm this we must show that $dy/dx = f(x)$ and that $y(x_0) = y_0$. The computations are as follows:

$$\frac{dy}{dx} = \frac{d}{dx}\left[y_0 + \int_{x_0}^{x} f(t)\,dt\right] = 0 + f(x) = f(x)$$

$$y(x_0) = y_0 + \int_{x_0}^{x_0} f(t)\,dt = y_0 + 0 = y_0$$

**▶ Example 2** In Example 6 of Section 5.2 we showed that the solution of the initial-value problem

$$\frac{dy}{dx} = \cos x, \quad y(0) = 1$$

is $y(x) = 1 + \sin x$. This initial-value problem can also be solved by applying Formula (11) with $f(x) = \cos x$, $x_0 = 0$, and $y_0 = 1$. This yields

$$y(x) = 1 + \int_0^x \cos t\,dt = 1 + \left[\sin t\right]_{t=0}^{x} = 1 + \sin x \quad \blacktriangleleft$$

In the last example we were able to perform the integration in Formula (11) and express the solution of the initial-value problem as an elementary function. However, sometimes this will not be possible, in which case the solution of the initial-value problem must be left in terms of an "unevaluated" integral. For example, from (11), the solution of the

initial-value problem $\dfrac{dy}{dx} = e^{-x^2}, \quad y(0) = 1$

is $$y(x) = 1 + \int_0^x e^{-t^2}\,dt$$

However, it can be shown that there is no way to express the integral in this solution as an elementary function. Thus, we have encountered a *new* function, which we regard to be *defined* by the integral. A close relative of this function, known as the ***error function***, plays an important role in probability and statistics; it is denoted by $\operatorname{erf}(x)$ and is defined as

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2}\,dt \tag{12}$$

Indeed, many of the most important functions in science and engineering are defined as integrals that have special names and notations associated with them. For example, the functions defined by

$$S(x) = \int_0^x \sin\left(\frac{\pi t^2}{2}\right) dt \quad \text{and} \quad C(x) = \int_0^x \cos\left(\frac{\pi t^2}{2}\right) dt \tag{13–14}$$

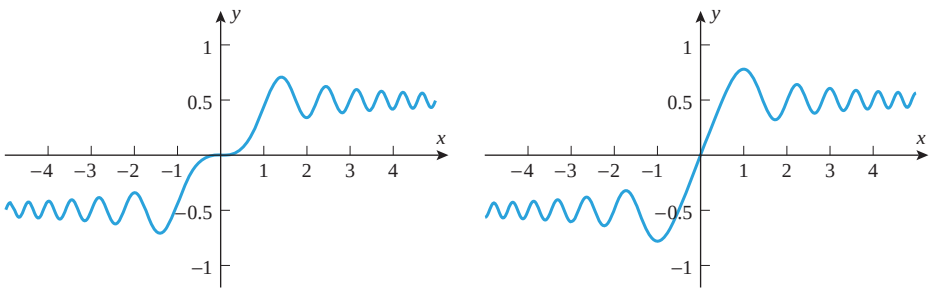
are called the ***Fresnel sine and cosine functions***, respectively, in honor of the French physicist Augustin Fresnel (1788–1827), who first encountered them in his study of diffraction of light waves.

## EVALUATING AND GRAPHING FUNCTIONS DEFINED BY INTEGRALS

The following values of $S(1)$ and $C(1)$ were produced by a CAS that has a built-in algorithm for approximating definite integrals:

$$S(1) = \int_0^1 \sin\left(\frac{\pi t^2}{2}\right) dt \approx 0.438259, \qquad C(1) = \int_0^1 \cos\left(\frac{\pi t^2}{2}\right) dt \approx 0.779893$$

To generate graphs of functions defined by integrals, computer programs choose a set of $x$-values in the domain, approximate the integral for each of those values, and then plot the resulting points. Thus, there is a lot of computation involved in generating such graphs, since each plotted point requires the approximation of an integral. The graphs of the Fresnel functions in Figure 5.10.4 were generated in this way using a CAS.



Fresnel sine function | Fresnel cosine function

▶ **Figure 5.10.4**

**REMARK** Although it required a considerable amount of computation to generate the graphs of the Fresnel functions, the derivatives of $S(x)$ and $C(x)$ are easy to obtain using Part 2 of the Fundamental Theorem of Calculus (5.6.3); they are

$$S'(x) = \sin\left(\frac{\pi x^2}{2}\right) \quad \text{and} \quad C'(x) = \cos\left(\frac{\pi x^2}{2}\right) \tag{15–16}$$

These derivatives can be used to determine the locations of the relative extrema and inflection points and to investigate other properties of $S(x)$ and $C(x)$.

## INTEGRALS WITH FUNCTIONS AS LIMITS OF INTEGRATION

Various applications can lead to integrals in which at least one of the limits of integration is a function of $x$. Some examples are

$$\int_x^1 \sqrt{\sin t}\,dt, \quad \int_{x^2}^{\sin x} \sqrt{t^3+1}\,dt, \quad \int_{\ln x}^{\pi} \frac{dt}{t^7-8}$$

We will complete this section by showing how to differentiate integrals of the form

$$\int_a^{g(x)} f(t)\,dt \tag{17}$$

where $a$ is constant. Derivatives of other kinds of integrals with functions as limits of integration will be discussed in the exercises.

To differentiate (17) we can view the integral as a composition $F(g(x))$, where

$$F(x) = \int_a^x f(t)\,dt$$

If we now apply the chain rule, we obtain

$$\frac{d}{dx}\left[\int_a^{g(x)} f(t)\,dt\right] = \frac{d}{dx}[F(g(x))] = F'(g(x))g'(x) = f(g(x))g'(x)$$

Theorem 5.6.3

Thus,

$$\frac{d}{dx}\left[\int_a^{g(x)} f(t)\,dt\right] = f(g(x))g'(x) \tag{18}$$

In words:

*To differentiate an integral with a constant lower limit and a function as the upper limit, substitute the upper limit into the integrand, and multiply by the derivative of the upper limit.*

### ▶ Example 3

$$\frac{d}{dx}\left[\int_1^{\sin x} (1-t^2)\,dt\right] = (1-\sin^2 x)\cos x = \cos^3 x \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 5.10 (See page 408 for answers.)

1. $\displaystyle\int_1^{1/e} \frac{1}{t}\,dt =$ _____
2. Estimate ln 2 using Definition 5.10.1 and
   (a) a left endpoint approximation with $n = 2$
   (b) a right endpoint approximation with $n = 2$.
3. $\pi^{1/(\ln \pi)} =$ _____
4. A solution to the initial-value problem
$$\frac{dy}{dx} = \cos x^3, \quad y(0) = 2$$
that is defined by an integral is $y =$ _____.
5. $\displaystyle\frac{d}{dx}\left[\int_0^{e^{-x}} \frac{1}{1+t^4}\,dt\right] =$ _____

## EXERCISE SET 5.10 Graphing Utility CAS

**1.** Sketch the curve $y = 1/t$, and shade a region under the curve whose area is
(a) $\ln 2$ (b) $-\ln 0.5$ (c) 2.

**2.** Sketch the curve $y = 1/t$, and shade two different regions under the curve whose areas are $\ln 1.5$.

**3.** Given that $\ln a = 2$ and $\ln c = 5$, find
(a) $\displaystyle\int_1^{ac} \frac{1}{t}\,dt$ (b) $\displaystyle\int_1^{1/c} \frac{1}{t}\,dt$
(c) $\displaystyle\int_1^{a/c} \frac{1}{t}\,dt$ (d) $\displaystyle\int_1^{a^3} \frac{1}{t}\,dt$.

**4.** Given that $\ln a = 9$, find
(a) $\displaystyle\int_1^{\sqrt{a}} \frac{1}{t}\,dt$ (b) $\displaystyle\int_1^{2a} \frac{1}{t}\,dt$
(c) $\displaystyle\int_1^{2/a} \frac{1}{t}\,dt$ (d) $\displaystyle\int_2^{a} \frac{1}{t}\,dt$.

**5.** Approximate $\ln 5$ using the midpoint rule with $n = 10$, and estimate the magnitude of the error by comparing your answer to that produced directly by a calculating utility.

**6.** Approximate $\ln 3$ using the midpoint rule with $n = 20$, and estimate the magnitude of the error by comparing your answer to that produced directly by a calculating utility.

**7.** Simplify the expression and state the values of $x$ for which your simplification is valid.
(a) $e^{-\ln x}$ (b) $e^{\ln x^2}$
(c) $\ln\left(e^{-x^2}\right)$ (d) $\ln(1/e^x)$
(e) $\exp(3\ln x)$ (f) $\ln(xe^x)$
(g) $\ln\left(e^{x-\sqrt[3]{x}}\right)$ (h) $e^{x-\ln x}$

**8.** (a) Let $f(x) = e^{-2x}$. Find the simplest exact value of the function $f(\ln 3)$.
(b) Let $f(x) = e^x + 3e^{-x}$. Find the simplest exact value of the function $f(\ln 2)$.

**9–10** Express the given quantity as a power of $e$.

**9.** (a) $3^{\pi}$ (b) $2^{\sqrt{2}}$

**10.** (a) $\pi^{-x}$ (b) $x^{2x}$, $x > 0$

**11–12** Find the limits by making appropriate substitutions in the limits given in Theorem 5.10.8.

**11.** (a) $\displaystyle\lim_{x\to+\infty}\left(1+\frac{1}{2x}\right)^x$ (b) $\displaystyle\lim_{x\to 0}(1+2x)^{1/x}$

**12.** (a) $\displaystyle\lim_{x\to+\infty}\left(1+\frac{3}{x}\right)^x$ (b) $\displaystyle\lim_{x\to 0}(1+x)^{1/(3x)}$

**13–14** Find $g'(x)$ using Part 2 of the Fundamental Theorem of Calculus, and check your answer by evaluating the integral and then differentiating.

**13.** $g(x) = \displaystyle\int_1^x (t^2 - t)\,dt$ **14.** $g(x) = \displaystyle\int_{\pi}^x (1 - \cos t)\,dt$

**15–16** Find the derivative using Formula (18), and check your answer by evaluating the integral and then differentiating the result.

**15.** (a) $\displaystyle\frac{d}{dx}\int_1^{x^3} \frac{1}{t}\,dt$ (b) $\displaystyle\frac{d}{dx}\int_1^{\ln x} e^t\,dt$

**16.** (a) $\displaystyle\frac{d}{dx}\int_{-1}^{x^2} \sqrt{t+1}\,dt$ (b) $\displaystyle\frac{d}{dx}\int_{\pi}^{1/x} \sin t\,dt$

**17.** Let $F(x) = \displaystyle\int_0^x \frac{\sin t}{t^2+1}\,dt$. Find
(a) $F(0)$ (b) $F'(0)$ (c) $F''(0)$.

**18.** Let $F(x) = \displaystyle\int_2^x \sqrt{3t^2+1}\,dt$. Find
(a) $F(2)$ (b) $F'(2)$ (c) $F''(2)$.

**19–22 True–False** Determine whether the equation is true or false. Explain your answer.

**19.** $\displaystyle\int_1^{1/a} \frac{1}{t}\,dt = -\int_1^a \frac{1}{t}\,dt$, for $0 < a$

**20.** $\displaystyle\int_1^{\sqrt{a}} \frac{1}{t}\,dt = \frac{1}{2}\int_1^a \frac{1}{t}\,dt$, for $0 < a$

**21.** $\displaystyle\int_{-1}^{e} \frac{1}{t}\,dt = 1$

**22.** $\displaystyle\int \frac{2x}{1+x^2}\,dx = \int_1^{1+x^2} \frac{1}{t}\,dt + C$

**23.** (a) Use Formula (18) to find

$$\frac{d}{dx}\int_1^{x^2} t\sqrt{1+t}\,dt$$

(b) Use a CAS to evaluate the integral and differentiate the resulting function.
(c) Use the simplification command of the CAS, if necessary, to confirm that the answers in parts (a) and (b) are the same.

**24.** Show that
(a) $\displaystyle\frac{d}{dx}\left[\int_x^a f(t)\,dt\right] = -f(x)$
(b) $\displaystyle\frac{d}{dx}\left[\int_{g(x)}^a f(t)\,dt\right] = -f(g(x))g'(x)$.

**25–26** Use the results in Exercise 24 to find the derivative.

**25.** (a) $\displaystyle\frac{d}{dx}\int_x^{\pi} \cos(t^3)\,dt$ (b) $\displaystyle\frac{d}{dx}\int_{\tan x}^3 \frac{t^2}{1+t^2}\,dt$

**26.** (a) $\displaystyle\frac{d}{dx}\int_x^0 \frac{1}{(t^2+1)^2}\,dt$ (b) $\displaystyle\frac{d}{dx}\int_{1/x}^{\pi} \cos^3 t\,dt$

**27.** Find

$$\frac{d}{dx}\left[\int_{3x}^{x^2} \frac{t-1}{t^2+1}\,dt\right]$$

by writing

$$\int_{3x}^{x^2} \frac{t-1}{t^2+1}\,dt = \int_{3x}^{0} \frac{t-1}{t^2+1}\,dt + \int_0^{x^2} \frac{t-1}{t^2+1}\,dt$$

**28.** Use Exercise 24(b) and the idea in Exercise 27 to show that

$$\frac{d}{dx}\int_{h(x)}^{g(x)} f(t)\,dt = f(g(x))g'(x) - f(h(x))h'(x)$$

**29.** Use the result obtained in Exercise 28 to perform the following differentiations:

(a) $\dfrac{d}{dx}\displaystyle\int_{x^2}^{x^3} \sin^2 t\,dt$ (b) $\dfrac{d}{dx}\displaystyle\int_{-x}^{x} \frac{1}{1+t}\,dt.$

**30.** Prove that the function

$$F(x) = \int_{x}^{5x} \frac{1}{t}\,dt$$

is constant on the interval $(0, +\infty)$ by using Exercise 28 to find $F'(x)$. What is that constant?

**FOCUS ON CONCEPTS**

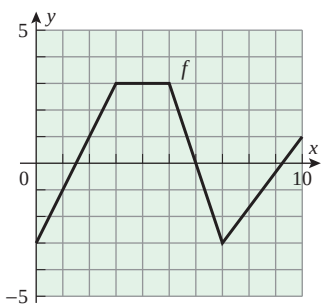
**31.** Let $F(x) = \int_0^x f(t)\,dt$, where $f$ is the function whose graph is shown in the accompanying figure.

(a) Find $F(0)$, $F(3)$, $F(5)$, $F(7)$, and $F(10)$.

(b) On what subintervals of the interval $[0, 10]$ is $F$ increasing? Decreasing?

(c) Where does $F$ have its maximum value? Its minimum value?

(d) Sketch the graph of $F$.



◀ **Figure Ex-31**

**32.** Determine the inflection point(s) for the graph of $F$ in Exercise 31.

**33–34** Express $F(x)$ in a piecewise form that does not involve an integral. ■

**33.** $F(x) = \displaystyle\int_{-1}^{x} |t|\,dt$

**34.** $F(x) = \displaystyle\int_{0}^{x} f(t)\,dt$, where $f(x) = \begin{cases} x, & 0 \le x \le 2 \\ 2, & x > 2 \end{cases}$

**35–38** Use Formula (11) to solve the initial-value problem. ■

**35.** $\dfrac{dy}{dx} = \dfrac{2x^2+1}{x}$, $y(1) = 2$ **36.** $\dfrac{dy}{dx} = \dfrac{x+1}{\sqrt{x}}$, $y(1) = 0$

**37.** $\dfrac{dy}{dx} = \sec^2 x - \sin x$, $y(\pi/4) = 1$

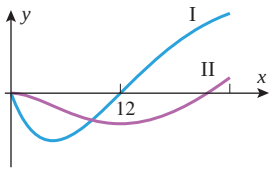
**38.** $\dfrac{dy}{dx} = \dfrac{1}{x \ln x}$, $y(e) = 1$

**39.** Suppose that at time $t = 0$ there are $P_0$ individuals who have disease X, and suppose that a certain model for the spread of the disease predicts that the disease will spread at the rate of $r(t)$ individuals per day. Write a formula for the number of individuals who will have disease X after $x$ days.

**40.** Suppose that $v(t)$ is the velocity function of a particle moving along an $s$-axis. Write a formula for the coordinate of the particle at time $T$ if the particle is at $s_1$ at time $t = 1$.

**FOCUS ON CONCEPTS**

**41.** The accompanying figure shows the graphs of $y = f(x)$ and $y = \int_0^x f(t)\,dt$. Determine which graph is which, and explain your reasoning.



◀ **Figure Ex-41**

**42.** (a) Make a conjecture about the value of the limit

$$\lim_{k\to 0}\int_1^b t^{k-1}\,dt \quad (b > 0)$$

(b) Check your conjecture by evaluating the integral and finding the limit. [*Hint:* Interpret the limit as the definition of the derivative of an exponential function.]

**43.** Let $F(x) = \int_0^x f(t)\,dt$, where $f$ is the function graphed in the accompanying figure.

(a) Where do the relative minima of $F$ occur?

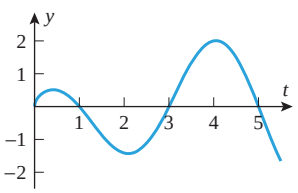
(b) Where do the relative maxima of $F$ occur?

(c) Where does the absolute maximum of $F$ on the interval $[0, 5]$ occur?

(d) Where does the absolute minimum of $F$ on the interval $[0, 5]$ occur?

(e) Where is $F$ concave up? Concave down?

(f) Sketch the graph of $F$.



◀ **Figure Ex-43**

C **44.** CAS programs have commands for working with most of the important nonelementary functions. Check your CAS documentation for information about the error function $\text{erf}(x)$ [see Formula (12)], and then complete the following.

(a) Generate the graph of $\text{erf}(x)$.

(b) Use the graph to make a conjecture about the existence and location of any relative maxima and minima of $\text{erf}(x)$.

(c) Check your conjecture in part (b) using the derivative of $\text{erf}(x)$.

(cont.)

(d) Use the graph to make a conjecture about the existence and location of any inflection points of $\operatorname{erf}(x)$.
(e) Check your conjecture in part (d) using the second derivative of $\operatorname{erf}(x)$.
(f) Use the graph to make a conjecture about the existence of horizontal asymptotes of $\operatorname{erf}(x)$.
(g) Check your conjecture in part (f) by using the CAS to find the limits of $\operatorname{erf}(x)$ as $x \to \pm\infty$.

**45.** The Fresnel sine and cosine functions $S(x)$ and $C(x)$ were defined in Formulas (13) and (14) and graphed in Figure 5.10.4. Their derivatives were given in Formulas (15) and (16).
(a) At what points does $C(x)$ have relative minima? Relative maxima?
(b) Where do the inflection points of $C(x)$ occur?
(c) Confirm that your answers in parts (a) and (b) are consistent with the graph of $C(x)$.

**46.** Find the limit

$$\lim_{h \to 0} \frac{1}{h} \int_x^{x+h} \ln t \, dt$$

**47.** Find a function $f$ and a number $a$ such that

$$4 + \int_a^x f(t)\, dt = e^{2x}$$

**48.** (a) Give a geometric argument to show that

$$\frac{1}{x+1} < \int_x^{x+1} \frac{1}{t}\, dt < \frac{1}{x}, \quad x > 0$$

(b) Use the result in part (a) to prove that

$$\frac{1}{x+1} < \ln\left(1 + \frac{1}{x}\right) < \frac{1}{x}, \quad x > 0$$

(c) Use the result in part (b) to prove that

$$e^{x/(x+1)} < \left(1 + \frac{1}{x}\right)^x < e, \quad x > 0$$

and hence that

$$\lim_{x \to +\infty} \left(1 + \frac{1}{x}\right)^x = e$$

(d) Use the result in part (b) to prove that

$$\left(1 + \frac{1}{x}\right)^x < e < \left(1 + \frac{1}{x}\right)^{x+1}, \quad x > 0$$

**49.** Use a graphing utility to generate the graph of

$$y = \left(1 + \frac{1}{x}\right)^{x+1} - \left(1 + \frac{1}{x}\right)^x$$

in the window $[0, 100] \times [0, 0.2]$, and use that graph and part (d) of Exercise 48 to make a rough estimate of the error in the approximation

$$e \approx \left(1 + \frac{1}{50}\right)^{50}$$

**50.** Prove: If $f$ is continuous on an open interval and $a$ is any point in that interval, then

$$F(x) = \int_a^x f(t)\, dt$$

is continuous on the interval.

**51.** **Writing** A student objects that it is circular reasoning to make the definition

$$\ln x = \int_1^x \frac{1}{t}\, dt$$

since to evaluate the integral we need to know the value of $\ln x$. Write a short paragraph that answers this student's objection.

**52.** **Writing** Write a short paragraph that compares Definition 5.10.1 with the definition of the natural logarithm function given in Chapter 0. Be sure to discuss the issues surrounding continuity and differentiability.

## ✔ QUICK CHECK ANSWERS 5.10

**1.** $-1$ **2.** (a) $\frac{5}{6}$ (b) $\frac{7}{12}$ **3.** $e$ **4.** $y = 2 + \int_0^x \cos t^3\, dt$ **5.** $-\dfrac{e^{-x}}{1 + e^{-4x}}$

## CHAPTER 5 REVIEW EXERCISES

Graphing Utility CAS

**1–8** Evaluate the integrals. ■

**1.** $\displaystyle\int \left[\frac{1}{2x^3} + 4\sqrt{x}\right] dx$

**2.** $\displaystyle\int [u^3 - 2u + 7]\, du$

**3.** $\displaystyle\int [4 \sin x + 2 \cos x]\, dx$

**4.** $\displaystyle\int \sec x (\tan x + \cos x)\, dx$

**5.** $\displaystyle\int [x^{-2/3} - 5e^x]\, dx$

**6.** $\displaystyle\int \left[\frac{3}{4x} - \sec^2 x\right] dx$

**7.** $\displaystyle\int \left[\frac{1}{1+x^2} + \frac{2}{\sqrt{1-x^2}}\right] dx$

**8.** $\displaystyle\int \left[\frac{12}{x\sqrt{x^2-1}} + \frac{1-x^4}{1+x^2}\right] dx$

**9.** Solve the initial-value problems.

(a) $\dfrac{dy}{dx} = \dfrac{1-x}{\sqrt{x}}, \; y(1) = 0$

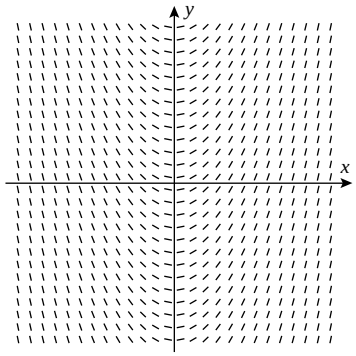
(b) $\dfrac{dy}{dx} = \cos x - 5e^x, \; y(0) = 0$

(c) $\dfrac{dy}{dx} = \sqrt[3]{x}, \; y(1) = 2$ (d) $\dfrac{dy}{dx} = xe^{x^2}, \; y(0) = 0$

**10.** The accompanying figure shows the slope field for a differential equation $dy/dx = f(x)$. Which of the following functions is most likely to be $f(x)$?

$$\sqrt{x}, \quad \sin x, \quad x^4, \quad x$$

Explain your reasoning.



◀ **Figure Ex-10**

**11.** (a) Show that the substitutions $u = \sec x$ and $u = \tan x$ produce different values for the integral

$$\int \sec^2 x \tan x \, dx$$

(b) Explain why both are correct.

**12.** Use the two substitutions in Exercise 11 to evaluate the definite integral

$$\int_0^{\pi/4} \sec^2 x \tan x \, dx$$

and confirm that they produce the same result.

**13.** Evaluate the integral

$$\int \frac{x}{(x^2-1)\sqrt{x^4-2x^2}}\, dx$$

by making the substitution $u = x^2 - 1$.

**14.** Evaluate the integral

$$\int \sqrt{1 + x^{-2/3}}\, dx$$

by making the substitution $u = 1 + x^{2/3}$.

C **15–18** Evaluate the integrals by hand, and check your answers with a CAS if you have one. ■

**15.** $\displaystyle\int \frac{\cos 3x}{\sqrt{5 + 2\sin 3x}}\, dx$ **16.** $\displaystyle\int \frac{\sqrt{3+\sqrt{x}}}{\sqrt{x}}\, dx$

**17.** $\displaystyle\int \frac{x^2}{(ax^3+b)^2}\, dx$ **18.** $\displaystyle\int x \sec^2(ax^2)\, dx$

**19.** Express

$$\sum_{k=4}^{18} k(k-3)$$

in sigma notation with
(a) $k = 0$ as the lower limit of summation
(b) $k = 5$ as the lower limit of summation.

**20.** (a) Fill in the blank:

$$1 + 3 + 5 + \cdots + (2n-1) = \sum_{k=1}^{n} _____$$

(b) Use part (a) to prove that the sum of the first $n$ consecutive odd integers is a perfect square.

**21.** Find the area under the graph of $f(x) = 4x - x^2$ over the interval $[0, 4]$ using Definition 5.4.3 with $x_k^*$ as the *right* endpoint of each subinterval.

**22.** Find the area under the graph of $f(x) = 5x - x^2$ over the interval $[0, 5]$ using Definition 5.4.3 with $x_k^*$ as the *left* endpoint of each subinterval.

**23–24** Use a calculating utility to find the left endpoint, right endpoint, and midpoint approximations to the area under the curve $y = f(x)$ over the stated interval using $n = 10$ subintervals. ■

**23.** $y = \ln x$; $[1, 2]$ **24.** $y = e^x$; $[0, 1]$

**25.** The *definite integral* of $f$ over the interval $[a, b]$ is defined as the limit

$$\int_a^b f(x)\, dx = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k$$

Explain what the various symbols on the right side of this equation mean.

**26.** Use a geometric argument to evaluate

$$\int_0^1 |2x - 1|\, dx$$

**27.** Suppose that

$$\int_0^1 f(x)\, dx = \tfrac{1}{2}, \quad \int_1^2 f(x)\, dx = \tfrac{1}{4},$$
$$\int_0^3 f(x)\, dx = -1, \quad \int_0^1 g(x)\, dx = 2$$

In each part, use this information to evaluate the given integral, if possible. If there is not enough information to evaluate the integral, then say so.

(a) $\displaystyle\int_0^2 f(x)\, dx$ (b) $\displaystyle\int_1^3 f(x)\, dx$ (c) $\displaystyle\int_2^3 5f(x)\, dx$

(d) $\displaystyle\int_1^0 g(x)\, dx$ (e) $\displaystyle\int_0^1 g(2x)\, dx$ (f) $\displaystyle\int_0^1 [g(x)]^2\, dx$

**28.** In parts (a)–(d), use the information in Exercise 27 to evaluate the given integral. If there is not enough information to evaluate the integral, then say so. *(cont.)*

(a) $\int_0^1 [f(x)+g(x)]\,dx$ (b) $\int_0^1 f(x)g(x)\,dx$

(c) $\int_0^1 \frac{f(x)}{g(x)}\,dx$ (d) $\int_0^1 [4g(x)-3f(x)]\,dx$

**29.** In each part, evaluate the integral. Where appropriate, you may use a geometric formula.

(a) $\int_{-1}^1 (1+\sqrt{1-x^2})\,dx$

(b) $\int_0^3 (x\sqrt{x^2+1}-\sqrt{9-x^2})\,dx$

(c) $\int_0^1 x\sqrt{1-x^4}\,dx$

**30.** In each part, find the limit by interpreting it as a limit of Riemann sums in which the interval $[0, 1]$ is divided into $n$ subintervals of equal length.

(a) $\lim_{n\to+\infty} \dfrac{\sqrt{1}+\sqrt{2}+\sqrt{3}+\cdots+\sqrt{n}}{n^{3/2}}$

(b) $\lim_{n\to+\infty} \dfrac{1^4+2^4+3^4+\cdots+n^4}{n^5}$

(c) $\lim_{n\to+\infty} \dfrac{e^{1/n}+e^{2/n}+e^{3/n}+\cdots+e^{n/n}}{n}$

**31–38** Evaluate the integrals using the Fundamental Theorem of Calculus and (if necessary) properties of the definite integral. ■

**31.** $\int_{-3}^0 (x^2-4x+7)\,dx$ **32.** $\int_{-1}^2 x(1+x^3)\,dx$

**33.** $\int_1^3 \frac{1}{x^2}\,dx$ **34.** $\int_1^8 (5x^{2/3}-4x^{-2})\,dx$

**35.** $\int_0^1 (x-\sec x\tan x)\,dx$

**36.** $\int_1^4 \left(\frac{3}{\sqrt{t}}-5\sqrt{t}-t^{-3/2}\right)dt$

**37.** $\int_0^2 |2x-3|\,dx$ **38.** $\int_0^{\pi/2} \left|\tfrac{1}{2}-\sin x\right|\,dx$

**39–42** Find the area under the curve $y=f(x)$ over the stated interval. ■

**39.** $f(x)=\sqrt{x}$; $[1, 9]$ **40.** $f(x)=x^{-3/5}$; $[1, 4]$

**41.** $f(x)=e^x$; $[1, 3]$ **42.** $f(x)=\frac{1}{x}$; $[1, e^3]$

**43.** Find the area that is above the $x$-axis but below the curve $y=(1-x)(x-2)$. Make a sketch of the region.

C **44.** Use a CAS to find the area of the region in the first quadrant that lies below the curve $y=x+x^2-x^3$ and above the $x$-axis.

**45–46** Sketch the curve and find the total area between the curve and the given interval on the $x$-axis. ■

**45.** $y=x^2-1$; $[0, 3]$ **46.** $y=\sqrt{x+1}-1$; $[-1, 1]$

**47.** Define $F(x)$ by

$$F(x)=\int_1^x (t^3+1)\,dt$$

(a) Use Part 2 of the Fundamental Theorem of Calculus to find $F'(x)$.

(b) Check the result in part (a) by first integrating and then differentiating.

**48.** Define $F(x)$ by

$$F(x)=\int_4^x \frac{1}{\sqrt{t}}\,dt$$

(a) Use Part 2 of the Fundamental Theorem of Calculus to find $F'(x)$.

(b) Check the result in part (a) by first integrating and then differentiating.

**49–54** Use Part 2 of the Fundamental Theorem of Calculus and (where necessary) Formula (18) of Section 5.10 to find the derivatives. ■

**49.** $\dfrac{d}{dx}\left[\int_0^x e^{t^2}\,dt\right]$ **50.** $\dfrac{d}{dx}\left[\int_0^x \dfrac{t}{\cos t^2}\,dt\right]$

**51.** $\dfrac{d}{dx}\left[\int_0^x |t-1|\,dt\right]$ **52.** $\dfrac{d}{dx}\left[\int_\pi^x \cos\sqrt{t}\,dt\right]$

**53.** $\dfrac{d}{dx}\left[\int_2^{\sin x} \dfrac{1}{1+t^3}\,dt\right]$ **54.** $\dfrac{d}{dx}\left[\int_e^{\sqrt{x}} (\ln t)^2\,dt\right]$

**55.** State the two parts of the Fundamental Theorem of Calculus, and explain what is meant by the statement "Differentiation and integration are inverse processes."

C **56.** Let $F(x)=\int_0^x \dfrac{t^2-3}{t^4+7}\,dt$.

(a) Find the intervals on which $F$ is increasing and those on which $F$ is decreasing.

(b) Find the open intervals on which $F$ is concave up and those on which $F$ is concave down.

(c) Find the $x$-values, if any, at which the function $F$ has absolute extrema.

(d) Use a CAS to graph $F$, and confirm that the results in parts (a), (b), and (c) are consistent with the graph.

**57.** (a) Use differentiation to prove that the function

$$F(x)=\int_0^x \frac{1}{1+t^2}\,dt+\int_0^{1/x} \frac{1}{1+t^2}\,dt$$

is constant on the interval $(0, +\infty)$.

(b) Determine the constant value of the function in part (a) and then interpret (a) as an identity involving the inverse tangent function.

**58.** What is the natural domain of the function

$$F(x)=\int_1^x \frac{1}{t^2-9}\,dt?$$

Explain your reasoning.

**59.** In each part, determine the values of $x$ for which $F(x)$ is positive, negative, or zero without performing the integration; explain your reasoning.

(a) $F(x) = \displaystyle\int_1^x \frac{t^4}{t^2+3}\,dt$ (b) $F(x) = \displaystyle\int_{-1}^x \sqrt{4-t^2}\,dt$

C **60.** Use a CAS to approximate the largest and smallest values of the integral

$$\int_{-1}^{x} \frac{t}{\sqrt{2+t^3}}\,dt$$

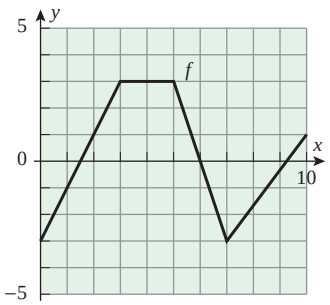
for $1 \le x \le 3$.

**61.** Find all values of $x^*$ in the stated interval that are guaranteed to exist by the Mean-Value Theorem for Integrals, and explain what these numbers represent.

(a) $f(x) = \sqrt{x}$; $[0, 3]$ (b) $f(x) = 1/x$; $[1, e]$

**62.** A 10-gram tumor is discovered in a laboratory rat on March 1. The tumor is growing at a rate of $r(t) = t/7$ grams per week, where $t$ denotes the number of weeks since March 1. What will be the mass of the tumor on June 7?

**63.** Use the graph of $f$ shown in the accompanying figure to find the average value of $f$ on the interval $[0, 10]$.



◀ **Figure Ex-63**

**64.** Find the average value of $f(x) = e^x + e^{-x}$ over the interval $\left[\ln\frac{1}{2}, \ln 2\right]$.

**65.** Derive the formulas for the position and velocity functions of a particle that moves with constant acceleration along a coordinate line.

**66.** The velocity of a particle moving along an $s$-axis is measured at 5 s intervals for 40 s, and the velocity function is modeled by a smooth curve. (The curve and the data points are shown in the accompanying figure.) Use this model in each part.

(a) Does the particle have constant acceleration? Explain your reasoning.

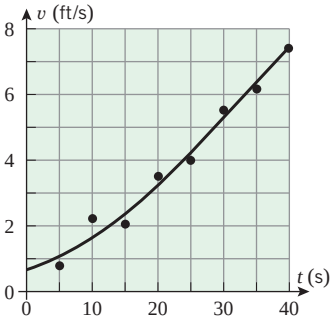
(b) Is there any 15 s time interval during which the acceleration is constant? Explain your reasoning.

(c) Estimate the distance traveled by the particle from time $t = 0$ to time $t = 40$.

(d) Estimate the average velocity of the particle over the 40 s time period.

(e) Is the particle ever slowing down during the 40 s time period? Explain your reasoning.

(f) Is there sufficient information for you to determine the $s$-coordinate of the particle at time $t = 10$? If so, find it. If not, explain what additional information you need.



◀ **Figure Ex-66**

**67–70** A particle moves along an $s$-axis. Use the given information to find the position function of the particle. ■

**67.** $v(t) = t^3 - 2t^2 + 1$; $s(0) = 1$

**68.** $a(t) = 4\cos 2t$; $v(0) = -1, s(0) = -3$

**69.** $v(t) = 2t - 3$; $s(1) = 5$

**70.** $a(t) = \cos t - 2t$; $v(0) = 0, s(0) = 0$

**71–74** A particle moves with a velocity of $v(t)$ m/s along an $s$-axis. Find the displacement and the distance traveled by the particle during the given time interval. ■

**71.** $v(t) = 2t - 4$; $0 \le t \le 6$

**72.** $v(t) = |t - 3|$; $0 \le t \le 5$

**73.** $v(t) = \dfrac{1}{2} - \dfrac{1}{t^2}$; $1 \le t \le 3$

**74.** $v(t) = \dfrac{3}{\sqrt{t}}$; $4 \le t \le 9$

**75–76** A particle moves with acceleration $a(t)$ m/s$^2$ along an $s$-axis and has velocity $v_0$ m/s at time $t = 0$. Find the displacement and the distance traveled by the particle during the given time interval. ■

**75.** $a(t) = -2$; $v_0 = 3$; $1 \le t \le 4$

**76.** $a(t) = \dfrac{1}{\sqrt{5t+1}}$; $v_0 = 2$; $0 \le t \le 3$

**77.** A car traveling 60 mi/h (= 88 ft/s) along a straight road decelerates at a constant rate of 10 ft/s$^2$.

(a) How long will it take until the speed is 45 mi/h?

(b) How far will the car travel before coming to a stop?

**78.** Suppose that the velocity function of a particle moving along an $s$-axis is $v(t) = 20t^2 - 100t + 50$ ft/s and that the particle is at the origin at time $t = 0$. Use a graphing utility to generate the graphs of $s(t)$, $v(t)$, and $a(t)$ for the first 6 s of motion.

**79.** A ball is thrown vertically upward from a height of $s_0$ ft with an initial velocity of $v_0$ ft/s. If the ball is caught at height $s_0$, determine its average speed through the air using the free-fall model.

**80.** A rock, dropped from an unknown height, strikes the ground with a speed of 24 m/s. Find the height from which the rock was dropped.

**81–88** Evaluate the integrals by making an appropriate substitution. ■

**81.** $\int_0^1 (2x+1)^4\,dx$

**82.** $\int_{-5}^0 x\sqrt{4-x}\,dx$

**83.** $\int_0^1 \frac{dx}{\sqrt{3x+1}}$

**84.** $\int_0^{\sqrt{\pi}} x\sin x^2\,dx$

**85.** $\int_0^1 \sin^2(\pi x)\cos(\pi x)\,dx$

**86.** $\int_e^{e^2} \frac{dx}{x\ln x}$

**87.** $\int_0^1 \frac{dx}{\sqrt{e^x}}$

**88.** $\int_0^{2/\sqrt{3}} \frac{1}{4+9x^2}\,dx$

**89.** Evaluate the limits.

(a) $\lim_{x\to+\infty}\left(1+\frac{1}{x}\right)^{2x}$ (b) $\lim_{x\to+\infty}\left(1+\frac{1}{3x}\right)^{x}$

**90.** Find a function $f$ and a number $a$ such that

$$2+\int_a^x f(t)\,dt = e^{3x}$$

## CHAPTER 5 MAKING CONNECTIONS

**1.** Consider a Riemann sum

$$\sum_{k=1}^{n} 2x_k^*\Delta x_k$$

for the integral of $f(x)=2x$ over an interval $[a,b]$.

(a) Show that if $x_k^*$ is the midpoint of the $k$th subinterval, the Riemann sum is a telescoping sum. (See Exercises 57–60 of Section 5.4 for other examples of telescoping sums.)

(b) Use part (a), Definition 5.5.1, and Theorem 5.5.2 to evaluate the definite integral of $f(x)=2x$ over $[a,b]$.

**2.** The function $f(x)=\sqrt{x}$ is continuous on $[0,4]$ and therefore integrable on this interval. Evaluate

$$\int_0^4 \sqrt{x}\,dx$$

by using Definition 5.5.1. Use subintervals of unequal length given by the partition

$$0 < 4(1)^2/n^2 < 4(2)^2/n^2 < \cdots < 4(n-1)^2/n^2 < 4$$

and let $x_k^*$ be the right endpoint of the $k$th subinterval.

**3.** Make appropriate modifications and repeat Exercise 2 for

$$\int_0^8 \sqrt[3]{x}\,dx$$

**4.** Given a continuous function $f$ and a positive real number $m$, let $g$ denote the function defined by the composition $g(x)=f(mx)$.

(a) Suppose that

$$\sum_{k=1}^{n} g(x_k^*)\Delta x_k$$

is any Riemann sum for the integral of $g$ over $[0,1]$. Use the correspondence $u_k = mx_k$, $u_k^* = mx_k^*$ to create a Riemann sum for the integral of $f$ over $[0,m]$. How are the values of the two Riemann sums related?

(b) Use part (a), Definition 5.5.1, and Theorem 5.5.2 to find an equation that relates the integral of $g$ over $[0,1]$ with the integral of $f$ over $[0,m]$.

(c) How is your answer to part (b) related to Theorem 5.9.1?

**5.** Given a continuous function $f$, let $g$ denote the function defined by $g(x)=2xf(x^2)$.

(a) Suppose that

$$\sum_{k=1}^{n} g(x_k^*)\Delta x_k$$

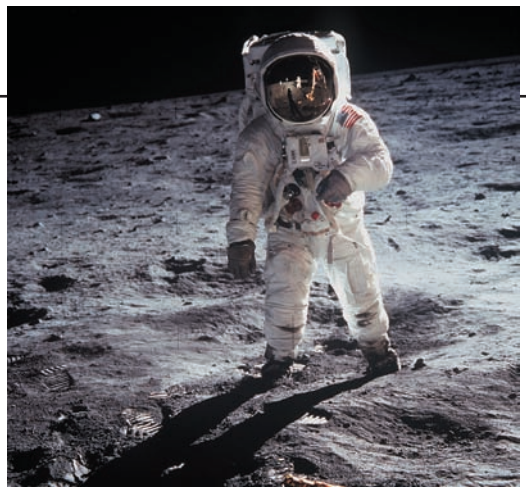
is any Riemann sum for the integral of $g$ over $[2,3]$, with $x_k^* = (x_k + x_{k-1})/2$ the midpoint of the $k$th subinterval. Use the correspondence $u_k = x_k^2$, $u_k^* = (x_k^*)^2$ to create a Riemann sum for the integral of $f$ over $[4,9]$. How are the values of the two Riemann sums related?

(b) Use part (a), Definition 5.5.1, and Theorem 5.5.2 to find an equation that relates the integral of $g$ over $[2,3]$ with the integral of $f$ over $[4,9]$.

(c) How is your answer to part (b) related to Theorem 5.9.1?

# 6

# APPLICATIONS OF THE DEFINITE INTEGRAL IN GEOMETRY, SCIENCE, AND ENGINEERING



Courtesy NASA

*Calculus is essential for the computations required to land an astronaut on the Moon.*

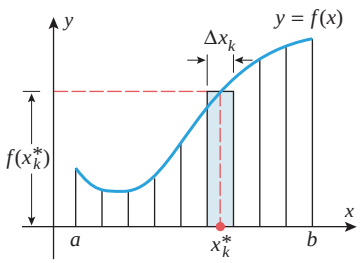
In the last chapter we introduced the definite integral as the limit of Riemann sums in the context of finding areas. However, Riemann sums and definite integrals have applications that extend far beyond the area problem. In this chapter we will show how Riemann sums and definite integrals arise in such problems as finding the volume and surface area of a solid, finding the length of a plane curve, calculating the work done by a force, finding the center of gravity of a planar region, finding the pressure and force exerted by a fluid on a submerged object, and finding properties of suspended cables.

Although these problems are diverse, the required calculations can all be approached by the same procedure that we used to find areas—breaking the required calculation into "small parts," making an approximation for each part, adding the approximations from the parts to produce a Riemann sum that approximates the entire quantity to be calculated, and then taking the limit of the Riemann sums to produce an exact result.

## 6.1 AREA BETWEEN TWO CURVES

*In the last chapter we showed how to find the area between a curve $y = f(x)$ and an interval on the $x$-axis. Here we will show how to find the area between two curves.*

### A REVIEW OF RIEMANN SUMS

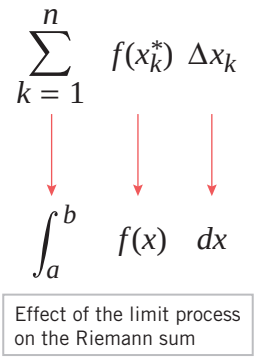


▲ **Figure 6.1.1**

Before we consider the problem of finding the area between two curves it will be helpful to review the basic principle that underlies the calculation of area as a definite integral. Recall that if $f$ is continuous and nonnegative on $[a, b]$, then the definite integral for the area $A$ under $y = f(x)$ over the interval $[a, b]$ is obtained in four steps (Figure 6.1.1):

- Divide the interval $[a, b]$ into $n$ subintervals, and use those subintervals to divide the region under the curve $y = f(x)$ into $n$ strips.
- Assuming that the width of the $k$th strip is $\Delta x_k$, approximate the area of that strip by the area $f(x_k^*)\Delta x_k$ of a rectangle of width $\Delta x_k$ and height $f(x_k^*)$, where $x_k^*$ is a point in the $k$th subinterval.
- Add the approximate areas of the strips to approximate the entire area $A$ by the Riemann sum:

$$A \approx \sum_{k=1}^{n} f(x_k^*)\Delta x_k$$



▲ **Figure 6.1.2**

- Take the limit of the Riemann sums as the number of subintervals increases and all their widths approach zero. This causes the error in the approximations to approach zero and produces the following definite integral for the exact area $A$:

$$A = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} f(x_k^*)\Delta x_k = \int_a^b f(x)\,dx$$

Figure 6.1.2 illustrates the effect that the limit process has on the various parts of the Riemann sum:

- The quantity $x_k^*$ in the Riemann sum becomes the variable $x$ in the definite integral.
- The interval width $\Delta x_k$ in the Riemann sum becomes the $dx$ in the definite integral.
- The interval $[a, b]$, which is the union of the subintervals with widths $\Delta x_1, \Delta x_2, \ldots, \Delta x_n$, does not appear explicitly in the Riemann sum but is represented by the upper and lower limits of integration in the definite integral.

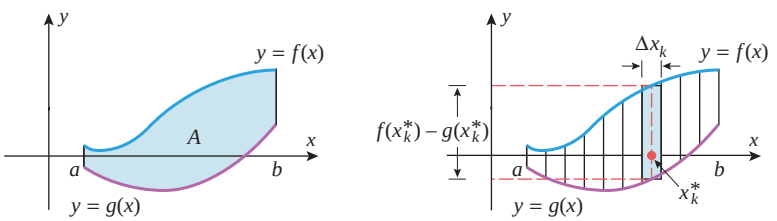
## AREA BETWEEN $y = f(x)$ AND $y = g(x)$

We will now consider the following extension of the area problem.

**6.1.1 FIRST AREA PROBLEM** Suppose that $f$ and $g$ are continuous functions on an interval $[a, b]$ and

$$f(x) \geq g(x) \quad \text{for} \quad a \leq x \leq b$$

[This means that the curve $y = f(x)$ lies above the curve $y = g(x)$ and that the two can touch but not cross.] Find the area $A$ of the region bounded above by $y = f(x)$, below by $y = g(x)$, and on the sides by the lines $x = a$ and $x = b$ (Figure 6.1.3*a*).



▶ **Figure 6.1.3**

To solve this problem we divide the interval $[a, b]$ into $n$ subintervals, which has the effect of subdividing the region into $n$ strips (Figure 6.1.3*b*). If we assume that the width of the $k$th strip is $\Delta x_k$, then the area of the strip can be approximated by the area of a rectangle of width $\Delta x_k$ and height $f(x_k^*) - g(x_k^*)$, where $x_k^*$ is a point in the $k$th subinterval. Adding these approximations yields the following Riemann sum that approximates the area $A$:

$$A \approx \sum_{k=1}^{n} [f(x_k^*) - g(x_k^*)]\Delta x_k$$

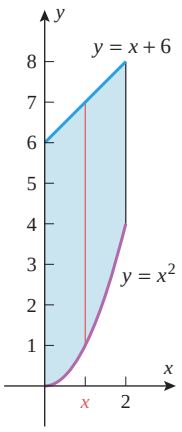
Taking the limit as $n$ increases and the widths of all the subintervals approach zero yields the following definite integral for the area $A$ between the curves:

$$A = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} [f(x_k^*) - g(x_k^*)]\Delta x_k = \int_a^b [f(x) - g(x)]\,dx$$

In summary, we have the following result.

**6.1.2 AREA FORMULA** If $f$ and $g$ are continuous functions on the interval $[a, b]$, and if $f(x) \geq g(x)$ for all $x$ in $[a, b]$, then the area of the region bounded above by $y = f(x)$, below by $y = g(x)$, on the left by the line $x = a$, and on the right by the line $x = b$ is

$$A = \int_a^b [f(x) - g(x)]\,dx \tag{1}$$



▲ Figure 6.1.4

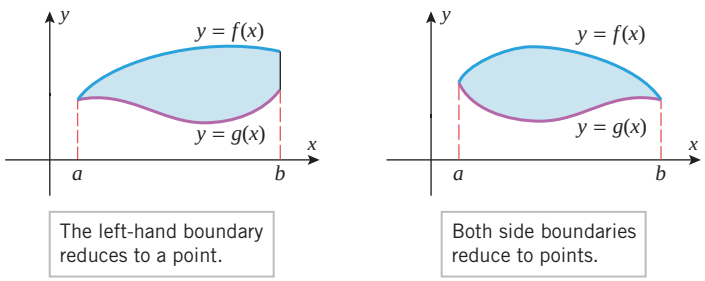
What does the integral in (1) represent if the graphs of $f$ and $g$ cross each other over the interval $[a, b]$? How would you find the area between the curves in this case?

▶ **Example 1** Find the area of the region bounded above by $y = x + 6$, bounded below by $y = x^2$, and bounded on the sides by the lines $x = 0$ and $x = 2$.

***Solution.*** The region and a cross section are shown in Figure 6.1.4. The cross section extends from $g(x) = x^2$ on the bottom to $f(x) = x + 6$ on the top. If the cross section is moved through the region, then its leftmost position will be $x = 0$ and its rightmost position will be $x = 2$. Thus, from (1)

$$A = \int_0^2 [(x + 6) - x^2]\,dx = \left[\frac{x^2}{2} + 6x - \frac{x^3}{3}\right]_0^2 = \frac{34}{3} - 0 = \frac{34}{3} \quad \blacktriangleleft$$

It is possible that the upper and lower boundaries of a region may intersect at one or both endpoints, in which case the sides of the region will be points, rather than vertical line segments (Figure 6.1.5). When that occurs you will have to determine the points of intersection to obtain the limits of integration.



▶ Figure 6.1.5

▶ **Example 2** Find the area of the region that is enclosed between the curves $y = x^2$ and $y = x + 6$.

***Solution.*** A sketch of the region (Figure 6.1.6) shows that the lower boundary is $y = x^2$ and the upper boundary is $y = x + 6$. At the endpoints of the region, the upper and lower boundaries have the same $y$-coordinates; thus, to find the endpoints we equate

$$y = x^2 \quad \text{and} \quad y = x + 6 \tag{2}$$

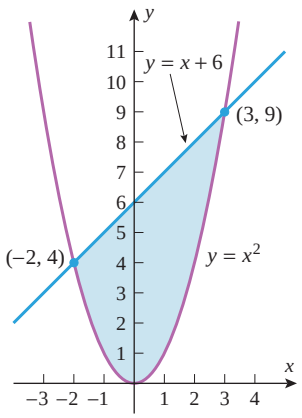
This yields

$$x^2 = x + 6 \quad \text{or} \quad x^2 - x - 6 = 0 \quad \text{or} \quad (x + 2)(x - 3) = 0$$

from which we obtain

$$x = -2 \quad \text{and} \quad x = 3$$

Although the $y$-coordinates of the endpoints are not essential to our solution, they may be obtained from (2) by substituting $x = -2$ and $x = 3$ in either equation. This yields $y = 4$ and $y = 9$, so the upper and lower boundaries intersect at $(-2, 4)$ and $(3, 9)$.



▲ Figure 6.1.6

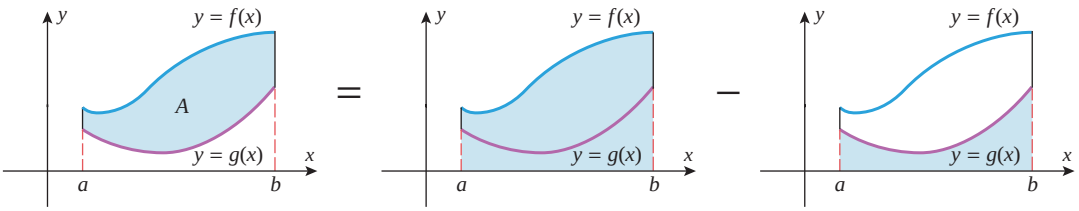
From (1) with $f(x) = x + 6$, $g(x) = x^2$, $a = -2$, and $b = 3$, we obtain the area

$$A = \int_{-2}^{3} [(x + 6) - x^2]\,dx = \left[\frac{x^2}{2} + 6x - \frac{x^3}{3}\right]_{-2}^{3} = \frac{27}{2} - \left(-\frac{22}{3}\right) = \frac{125}{6} \quad \blacktriangleleft$$

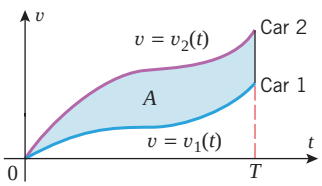
In the case where $f$ and $g$ are *nonnegative* on the interval $[a, b]$, the formula

$$A = \int_a^b [f(x) - g(x)]\,dx = \int_a^b f(x)\,dx - \int_a^b g(x)\,dx$$

states that the area $A$ between the curves can be obtained by subtracting the area under $y = g(x)$ from the area under $y = f(x)$ (Figure 6.1.7).



▲ **Figure 6.1.7**



▲ **Figure 6.1.8**

► **Example 3** Figure 6.1.8 shows velocity versus time curves for two race cars that move along a straight track, starting from rest at the same time. Give a physical interpretation of the area $A$ between the curves over the interval $0 \le t \le T$.

***Solution.*** From (1)

$$A = \int_0^T [v_2(t) - v_1(t)]\,dt = \int_0^T v_2(t)\,dt - \int_0^T v_1(t)\,dt$$

Since $v_1$ and $v_2$ are nonnegative functions on $[0, T]$, it follows from Formula (4) of Section 5.7 that the integral of $v_1$ over $[0, T]$ is the distance traveled by car 1 during the time interval $0 \le t \le T$, and the integral of $v_2$ over $[0, T]$ is the distance traveled by car 2 during the same time interval. Since $v_1(t) \le v_2(t)$ on $[0, T]$, car 2 travels farther than car 1 does over the time interval $0 \le t \le T$, and the area $A$ represents the distance by which car 2 is ahead of car 1 at time $T$. ◄

Some regions may require careful thought to determine the integrand and limits of integration in (1). Here is a systematic procedure that you can follow to set up this formula.

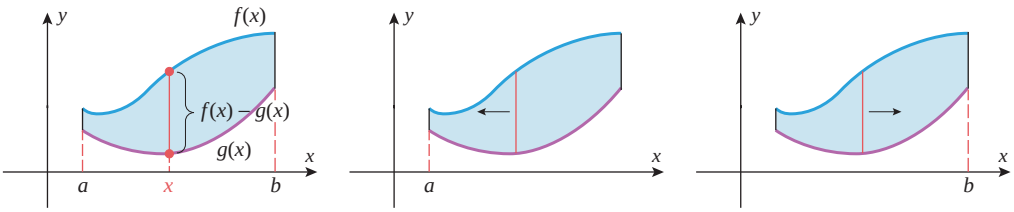
It is not necessary to make an extremely accurate sketch in Step 1; the only purpose of the sketch is to determine which curve is the upper boundary and which is the lower boundary.

***Finding the Limits of Integration for the Area Between Two Curves***

**Step 1.** Sketch the region and then draw a vertical line segment through the region at an arbitrary point $x$ on the $x$-axis, connecting the top and bottom boundaries (Figure 6.1.9*a*).

**Step 2.** The $y$-coordinate of the top endpoint of the line segment sketched in Step 1 will be $f(x)$, the bottom one $g(x)$, and the length of the line segment will be $f(x) - g(x)$. This is the integrand in (1).

**Step 3.** To determine the limits of integration, imagine moving the line segment left and then right. The leftmost position at which the line segment intersects the region is $x = a$ and the rightmost is $x = b$ (Figures 6.1.9*b* and 6.1.9*c*).



▲ **Figure 6.1.9**

There is a useful way of thinking about this procedure:

*If you view the vertical line segment as the "cross section" of the region at the point x, then Formula (1) states that the area between the curves is obtained by integrating the length of the cross section over the interval* $[a, b]$.

It is possible for the upper or lower boundary of a region to consist of two or more different curves, in which case it will be convenient to subdivide the region into smaller pieces in order to apply Formula (1). This is illustrated in the next example.

▶ **Example 4** Find the area of the region enclosed by $x = y^2$ and $y = x - 2$.

***Solution.*** To determine the appropriate boundaries of the region, we need to know where the curves $x = y^2$ and $y = x - 2$ intersect. In Example 2 we found intersections by equating the expressions for $y$. Here it is easier to rewrite the latter equation as $x = y + 2$ and equate the expressions for $x$, namely,

$$x = y^2 \quad \text{and} \quad x = y + 2 \tag{3}$$

This yields

$$y^2 = y + 2 \quad \text{or} \quad y^2 - y - 2 = 0 \quad \text{or} \quad (y + 1)(y - 2) = 0$$

from which we obtain $y = -1$, $y = 2$. Substituting these values in either equation in (3) we see that the corresponding $x$-values are $x = 1$ and $x = 4$, respectively, so the points of intersection are $(1, -1)$ and $(4, 2)$ (Figure 6.1.10*a*).

To apply Formula (1), the equations of the boundaries must be written so that $y$ is expressed explicitly as a function of $x$. The upper boundary can be written as $y = \sqrt{x}$ (rewrite $x = y^2$ as $y = \pm\sqrt{x}$ and choose the $+$ for the upper portion of the curve). The lower boundary consists of two parts:

$$y = -\sqrt{x} \quad \text{for} \quad 0 \le x \le 1 \qquad \text{and} \qquad y = x - 2 \quad \text{for} \quad 1 \le x \le 4$$

(Figure 6.1.10*b*). Because of this change in the formula for the lower boundary, it is necessary to divide the region into two parts and find the area of each part separately.

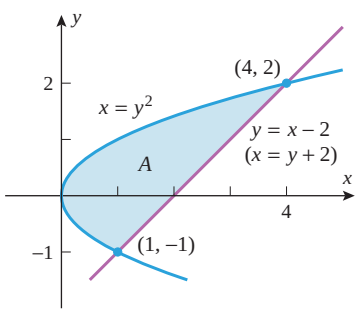
From (1) with $f(x) = \sqrt{x}$, $g(x) = -\sqrt{x}$, $a = 0$, and $b = 1$, we obtain

$$A_1 = \int_0^1 [\sqrt{x} - (-\sqrt{x})]\,dx = 2\int_0^1 \sqrt{x}\,dx = 2\left[\frac{2}{3}x^{3/2}\right]_0^1 = \frac{4}{3} - 0 = \frac{4}{3}$$

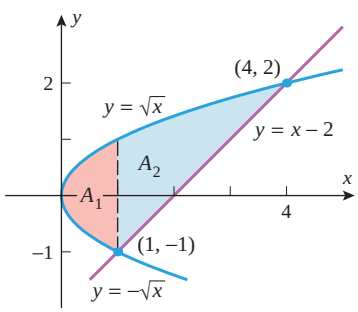
From (1) with $f(x) = \sqrt{x}$, $g(x) = x - 2$, $a = 1$, and $b = 4$, we obtain

$$A_2 = \int_1^4 [\sqrt{x} - (x - 2)]\,dx = \int_1^4 (\sqrt{x} - x + 2)\,dx$$

$$= \left[\frac{2}{3}x^{3/2} - \frac{1}{2}x^2 + 2x\right]_1^4 = \left(\frac{16}{3} - 8 + 8\right) - \left(\frac{2}{3} - \frac{1}{2} + 2\right) = \frac{19}{6}$$



(*a*)



(*b*)

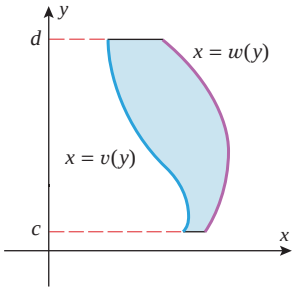
▲ **Figure 6.1.10**

Thus, the area of the entire region is

$$A = A_1 + A_2 = \frac{4}{3} + \frac{19}{6} = \frac{9}{2} \quad \blacktriangleleft$$

## REVERSING THE ROLES OF $x$ AND $y$

Sometimes it is much easier to find the area of a region by integrating with respect to $y$ rather than $x$. We will now show how this can be done.



▲ Figure 6.1.11

**6.1.3 SECOND AREA PROBLEM** Suppose that $w$ and $v$ are continuous functions of $y$ on an interval $[c, d]$ and that

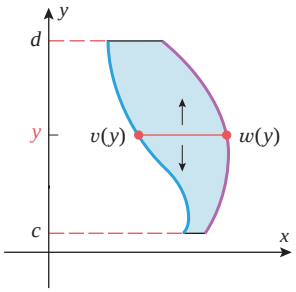
$$w(y) \geq v(y) \quad \text{for} \quad c \leq y \leq d$$

[This means that the curve $x = w(y)$ lies to the right of the curve $x = v(y)$ and that the two can touch but not cross.] Find the area $A$ of the region bounded on the left by $x = v(y)$, on the right by $x = w(y)$, and above and below by the lines $y = d$ and $y = c$ (Figure 6.1.11).

Proceeding as in the derivation of (1), but with the roles of $x$ and $y$ reversed, leads to the following analog of 6.1.2.

**6.1.4 AREA FORMULA** If $w$ and $v$ are continuous functions and if $w(y) \geq v(y)$ for all $y$ in $[c, d]$, then the area of the region bounded on the left by $x = v(y)$, on the right by $x = w(y)$, below by $y = c$, and above by $y = d$ is

$$A = \int_c^d [w(y) - v(y)]\, dy \tag{4}$$



▲ Figure 6.1.12

The guiding principle in applying this formula is the same as with (1): The integrand in (4) can be viewed as the length of the horizontal cross section at an arbitrary point $y$ on the $y$-axis, in which case Formula (4) states that the area can be obtained by integrating the length of the horizontal cross section over the interval $[c, d]$ on the $y$-axis (Figure 6.1.12).

In Example 4, we split the region into two parts to facilitate integrating with respect to $x$. In the next example we will see that splitting this region can be avoided if we integrate with respect to $y$.

**▶ Example 5** Find the area of the region enclosed by $x = y^2$ and $y = x - 2$, integrating with respect to $y$.

***Solution.*** As indicated in Figure 6.1.10 the left boundary is $x = y^2$, the right boundary is $y = x - 2$, and the region extends over the interval $-1 \leq y \leq 2$. However, to apply (4) the equations for the boundaries must be written so that $x$ is expressed explicitly as a function of $y$. Thus, we rewrite $y = x - 2$ as $x = y + 2$. It now follows from (4) that

$$A = \int_{-1}^{2} [(y + 2) - y^2]\, dy = \left[\frac{y^2}{2} + 2y - \frac{y^3}{3}\right]_{-1}^{2} = \frac{9}{2}$$

which agrees with the result obtained in Example 4. ◀

The choice between Formulas (1) and (4) is usually dictated by the shape of the region and which formula requires the least amount of splitting. However, sometimes one might choose the formula that requires more splitting because it is easier to evaluate the resulting integrals.

## ✔ QUICK CHECK EXERCISES 6.1 (See page 421 for answers.)

1. An integral expression for the area of the region between the curves $y = 20 - 3x^2$ and $y = e^x$ and bounded on the sides by $x = 0$ and $x = 2$ is _____.
2. An integral expression for the area of the parallelogram bounded by $y = 2x + 8$, $y = 2x - 3$, $x = -1$, and $x = 5$ is _____. The value of this integral is _____.
3. (a) The points of intersection for the circle $x^2 + y^2 = 4$ and the line $y = x + 2$ are _____ and _____.
   (b) Expressed as a definite integral with respect to $x$, _____ gives the area of the region inside the circle $x^2 + y^2 = 4$ and above the line $y = x + 2$.
   (c) Expressed as a definite integral with respect to $y$, _____ gives the area of the region described in part (b).
4. The area of the region enclosed by the curves $y = x^2$ and $y = \sqrt[3]{x}$ is _____.

## EXERCISE SET 6.1 Graphing Utility CAS

**1–4** Find the area of the shaded region.

1. 

2. 

3. 

4. 

**5–6** Find the area of the shaded region by (a) integrating with respect to $x$ and (b) integrating with respect to $y$.

5. 

6. 

**7–18** Sketch the region enclosed by the curves and find its area.

7. $y = x^2$, $y = \sqrt{x}$, $x = \frac{1}{4}$, $x = 1$
8. $y = x^3 - 4x$, $y = 0$, $x = 0$, $x = 2$
9. $y = \cos 2x$, $y = 0$, $x = \pi/4$, $x = \pi/2$
10. $y = \sec^2 x$, $y = 2$, $x = -\pi/4$, $x = \pi/4$
11. $x = \sin y$, $x = 0$, $y = \pi/4$, $y = 3\pi/4$
12. $x^2 = y$, $x = y - 2$
13. $y = e^x$, $y = e^{2x}$, $x = 0$, $x = \ln 2$
14. $x = 1/y$, $x = 0$, $y = 1$, $y = e$
15. $y = \dfrac{2}{1 + x^2}$, $y = |x|$
16. $y = \dfrac{1}{\sqrt{1 - x^2}}$, $y = 2$
17. $y = 2 + |x - 1|$, $y = -\frac{1}{5}x + 7$
18. $y = x$, $y = 4x$, $y = -x + 2$

**19–26** Use a graphing utility, where helpful, to find the area of the region enclosed by the curves.

19. $y = x^3 - 4x^2 + 3x$, $y = 0$
20. $y = x^3 - 2x^2$, $y = 2x^2 - 3x$
21. $y = \sin x$, $y = \cos x$, $x = 0$, $x = 2\pi$
22. $y = x^3 - 4x$, $y = 0$
23. $x = y^3 - y$, $x = 0$
24. $x = y^3 - 4y^2 + 3y$, $x = y^2 - y$
25. $y = xe^{x^2}$, $y = 2|x|$
26. $y = \dfrac{1}{x\sqrt{1 - (\ln x)^2}}$, $y = \dfrac{3}{x}$

**27–30 True–False** Determine whether the statement is true or false. Explain your answer. [In each exercise, assume that $f$ and $g$ are distinct continuous functions on $[a, b]$ and that $A$ denotes the area of the region bounded by the graphs of $y = f(x)$, $y = g(x)$, $x = a$, and $x = b$.]

27. If $f$ and $g$ differ by a positive constant $c$, then $A = c(b - a)$.
28. If $$\int_a^b [f(x) - g(x)]\,dx = -3$$ then $A = 3$.
29. If $$\int_a^b [f(x) - g(x)]\,dx = 0$$ then the graphs of $y = f(x)$ and $y = g(x)$ cross at least once on $[a, b]$.
30. If $$A = \left| \int_a^b [f(x) - g(x)]\,dx \right|$$ then the graphs of $y = f(x)$ and $y = g(x)$ don't cross on $[a, b]$.

**31.** Estimate the value of $k$ $(0 < k < 1)$ so that the region enclosed by $y = 1/\sqrt{1 - x^2}$, $y = x$, $x = 0$, and $x = k$ has an area of 1 square unit.

**32.** Estimate the area of the region in the first quadrant enclosed by $y = \sin 2x$ and $y = \sin^{-1} x$.

**C 33.** Use a CAS to find the area enclosed by $y = 3 - 2x$ and $y = x^6 + 2x^5 - 3x^4 + x^2$.

**C 34.** Use a CAS to find the exact area enclosed by the curves $y = x^5 - 2x^3 - 3x$ and $y = x^3$.

**35.** Find a horizontal line $y = k$ that divides the area between $y = x^2$ and $y = 9$ into two equal parts.

**36.** Find a vertical line $x = k$ that divides the area enclosed by $x = \sqrt{y}$, $x = 2$, and $y = 0$ into two equal parts.

**37.** (a) Find the area of the region enclosed by the parabola $y = 2x - x^2$ and the $x$-axis.

(b) Find the value of $m$ so that the line $y = mx$ divides the region in part (a) into two regions of equal area.

**38.** Find the area between the curve $y = \sin x$ and the line segment joining the points $(0, 0)$ and $(5\pi/6, 1/2)$ on the curve.

**39–42** Use Newton's Method (Section 4.7), where needed, to approximate the $x$-coordinates of the intersections of the curves to at least four decimal places, and then use those approximations to approximate the area of the region. ■

**39.** The region that lies below the curve $y = \sin x$ and above the line $y = 0.2x$, where $x \geq 0$.

**40.** The region enclosed by the graphs of $y = x^2$ and $y = \cos x$.

**41.** The region enclosed by the graphs of $y = (\ln x)/x$ and $y = x - 2$.

**42.** The region enclosed by the graphs of $y = 3 - 2\cos x$ and $y = 2/(1 + x^2)$.

**43.** Find the area of the region that is enclosed by the curves $y = x^2 - 1$ and $y = 2\sin x$.

**C 44.** Referring to the accompanying figure, use a CAS to estimate the value of $k$ so that the areas of the shaded regions are equal.

***Source:*** This exercise is based on Problem A1 that was posed in the Fifty-Fourth Annual William Lowell Putnam Mathematical Competition.

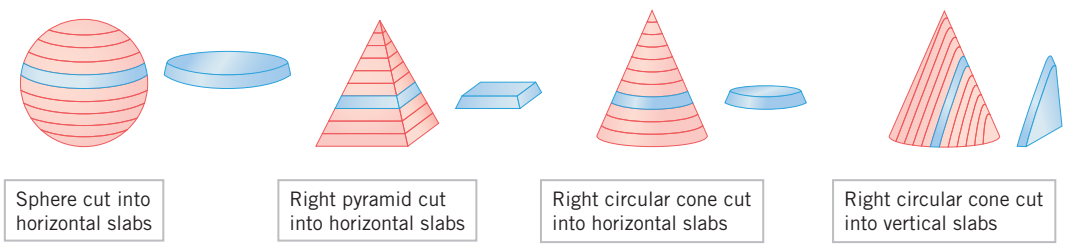
# 6.2 VOLUMES BY SLICING; DISKS AND WASHERS

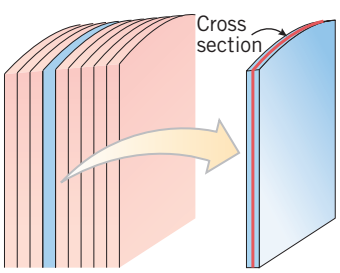
*In the last section we showed that the area of a plane region bounded by two curves can be obtained by integrating the length of a general cross section over an appropriate interval. In this section we will see that the same basic principle can be used to find volumes of certain three-dimensional solids.*

## VOLUMES BY SLICING

Recall that the underlying principle for finding the area of a plane region is to divide the region into thin strips, approximate the area of each strip by the area of a rectangle, add the approximations to form a Riemann sum, and take the limit of the Riemann sums to produce an integral for the area. Under appropriate conditions, the same strategy can be used to find the volume of a solid. The idea is to divide the solid into thin slabs, approximate the volume of each slab, add the approximations to form a Riemann sum, and take the limit of the Riemann sums to produce an integral for the volume (Figure 6.2.1).



▲ **Figure 6.2.1**



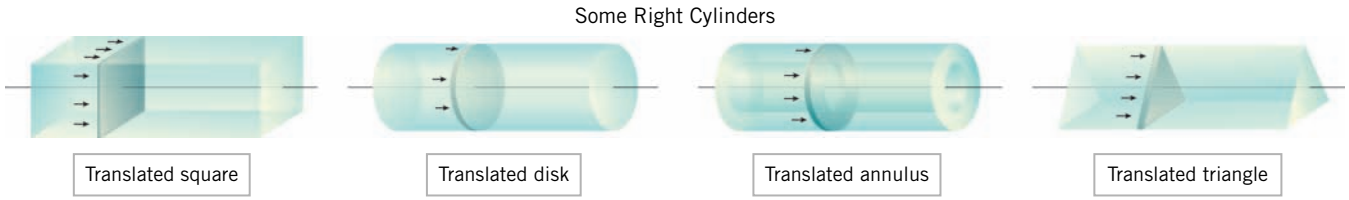
▲ **Figure 6.2.2**

What makes this method work is the fact that a *thin* slab has a cross section that does not vary much in size or shape, which, as we will see, makes its volume easy to approximate (Figure 6.2.2). Moreover, the thinner the slab, the less variation in its cross sections and the better the approximation. Thus, once we approximate the volumes of the slabs, we can set up a Riemann sum whose limit is the volume of the entire solid. We will give the details shortly, but first we need to discuss how to find the volume of a solid whose cross sections do not vary in size and shape (i.e., are congruent).

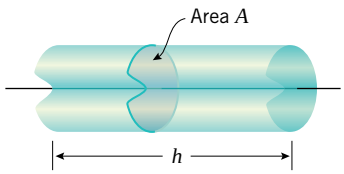
One of the simplest examples of a solid with congruent cross sections is a right circular cylinder of radius $r$, since all cross sections taken perpendicular to the central axis are circular regions of radius $r$. The volume $V$ of a right circular cylinder of radius $r$ and height $h$ can be expressed in terms of the height and the area of a cross section as

$$V = \pi r^2 h = [\text{area of a cross section}] \times [\text{height}] \qquad (1)$$

This is a special case of a more general volume formula that applies to solids called right cylinders. A ***right cylinder*** is a solid that is generated when a plane region is translated along a line or ***axis*** that is perpendicular to the region (Figure 6.2.3).



▲ **Figure 6.2.3**



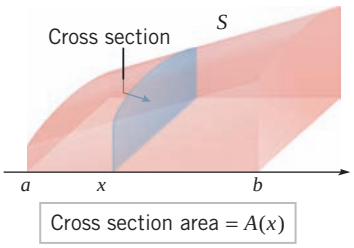
▲ **Figure 6.2.4**

If a right cylinder is generated by translating a region of area $A$ through a distance $h$, then $h$ is called the ***height*** (or sometimes the ***width***) of the cylinder, and the volume $V$ of the cylinder is defined to be

$$V = A \cdot h = [\text{area of a cross section}] \times [\text{height}] \tag{2}$$

(Figure 6.2.4). Note that this is consistent with Formula (1) for the volume of a right *circular* cylinder.

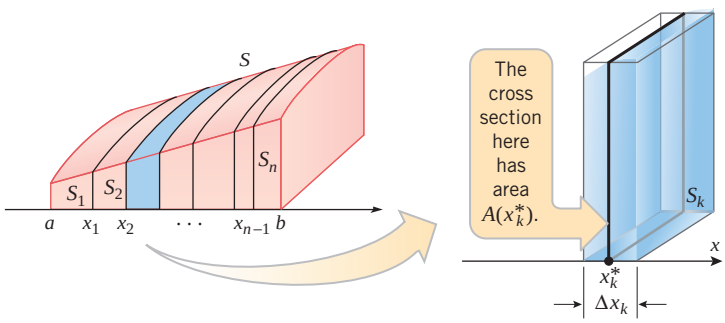
We now have all of the tools required to solve the following problem.



▲ **Figure 6.2.5**

**6.2.1 PROBLEM** Let $S$ be a solid that extends along the $x$-axis and is bounded on the left and right, respectively, by the planes that are perpendicular to the $x$-axis at $x = a$ and $x = b$ (Figure 6.2.5). Find the volume $V$ of the solid, assuming that its cross-sectional area $A(x)$ is known at each $x$ in the interval $[a, b]$.

To solve this problem we begin by dividing the interval $[a, b]$ into $n$ subintervals, thereby dividing the solid into $n$ slabs as shown in the left part of Figure 6.2.6. If we assume that the width of the $k$th subinterval is $\Delta x_k$, then the volume of the $k$th slab can be approximated by the volume $A(x_k^*)\Delta x_k$ of a right cylinder of width (height) $\Delta x_k$ and cross-sectional area $A(x_k^*)$, where $x_k^*$ is a point in the $k$th subinterval (see the right part of Figure 6.2.6).



▶ **Figure 6.2.6**

Adding these approximations yields the following Riemann sum that approximates the volume $V$:

$$V \approx \sum_{k=1}^{n} A(x_k^*)\Delta x_k$$

Taking the limit as $n$ increases and the widths of all the subintervals approach zero yields the definite integral

$$V = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} A(x_k^*)\Delta x_k = \int_a^b A(x)\,dx$$

In summary, we have the following result.

It is understood in our calculations of volume that the units of volume are the cubed units of length [e.g., cubic inches ($in^3$) or cubic meters ($m^3$)].

**6.2.2 VOLUME FORMULA** Let $S$ be a solid bounded by two parallel planes perpendicular to the $x$-axis at $x = a$ and $x = b$. If, for each $x$ in $[a, b]$, the cross-sectional area of $S$ perpendicular to the $x$-axis is $A(x)$, then the volume of the solid is

$$V = \int_a^b A(x)\,dx \tag{3}$$

provided $A(x)$ is integrable.

There is a similar result for cross sections perpendicular to the $y$-axis.

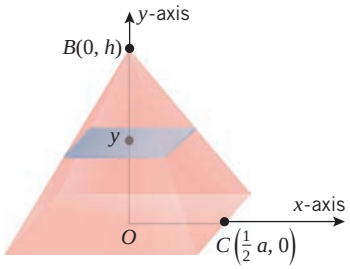
**6.2.3 VOLUME FORMULA** Let $S$ be a solid bounded by two parallel planes perpendicular to the $y$-axis at $y = c$ and $y = d$. If, for each $y$ in $[c, d]$, the cross-sectional area of $S$ perpendicular to the $y$-axis is $A(y)$, then the volume of the solid is

$$V = \int_c^d A(y)\,dy \tag{4}$$

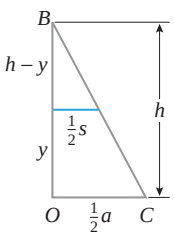
provided $A(y)$ is integrable.

In words, these formulas state:

*The volume of a solid can be obtained by integrating the cross-sectional area from one end of the solid to the other.*



(a)



(b)

▲ Figure 6.2.7

▶ **Example 1** Derive the formula for the volume of a right pyramid whose altitude is $h$ and whose base is a square with sides of length $a$.

***Solution.*** As illustrated in Figure 6.2.7*a*, we introduce a rectangular coordinate system in which the $y$-axis passes through the apex and is perpendicular to the base, and the $x$-axis passes through the base and is parallel to a side of the base.

At any $y$ in the interval $[0, h]$ on the $y$-axis, the cross section perpendicular to the $y$-axis is a square. If $s$ denotes the length of a side of this square, then by similar triangles (Figure 6.2.7*b*)

$$\frac{\frac{1}{2}s}{\frac{1}{2}a} = \frac{h - y}{h} \quad \text{or} \quad s = \frac{a}{h}(h - y)$$

Thus, the area $A(y)$ of the cross section at $y$ is

$$A(y) = s^2 = \frac{a^2}{h^2}(h - y)^2$$

and by (4) the volume is

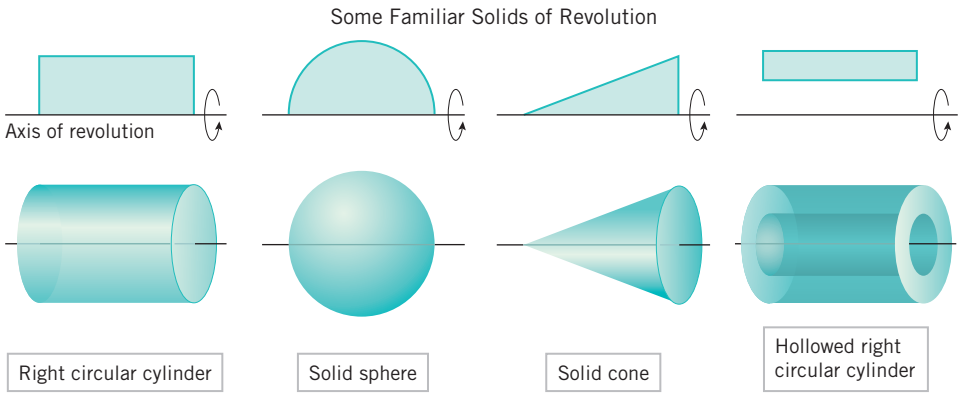
$$V = \int_0^h A(y)\,dy = \int_0^h \frac{a^2}{h^2}(h-y)^2\,dy = \frac{a^2}{h^2}\int_0^h (h-y)^2\,dy$$

$$= \frac{a^2}{h^2}\left[-\frac{1}{3}(h-y)^3\right]_{y=0}^{h} = \frac{a^2}{h^2}\left[0+\frac{1}{3}h^3\right] = \frac{1}{3}a^2h$$

That is, the volume is $\frac{1}{3}$ of the area of the base times the altitude. ◀

## SOLIDS OF REVOLUTION

A ***solid of revolution*** is a solid that is generated by revolving a plane region about a line that lies in the same plane as the region; the line is called the ***axis of revolution***. Many familiar solids are of this type (Figure 6.2.8).

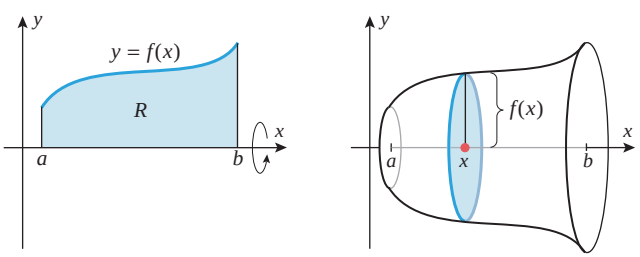


▶ **Figure 6.2.8**

## VOLUMES BY DISKS PERPENDICULAR TO THE *x*-AXIS

We will be interested in the following general problem.

**6.2.4 PROBLEM** Let $f$ be continuous and nonnegative on $[a, b]$, and let $R$ be the region that is bounded above by $y = f(x)$, below by the $x$-axis, and on the sides by the lines $x = a$ and $x = b$ (Figure 6.2.9*a*). Find the volume of the solid of revolution that is generated by revolving the region $R$ about the $x$-axis.



▶ **Figure 6.2.9**

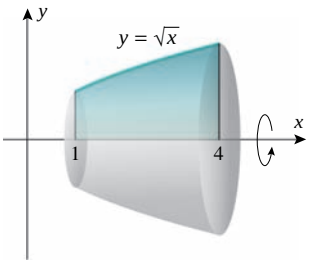
We can solve this problem by slicing. For this purpose, observe that the cross section of the solid taken perpendicular to the $x$-axis at the point $x$ is a circular disk of radius $f(x)$ (Figure 6.2.9*b*). The area of this region is

$$A(x) = \pi[f(x)]^2$$

Thus, from (3) the volume of the solid is

$$V = \int_a^b \pi[f(x)]^2\,dx \tag{5}$$

Because the cross sections are disk shaped, the application of this formula is called the ***method of disks***.

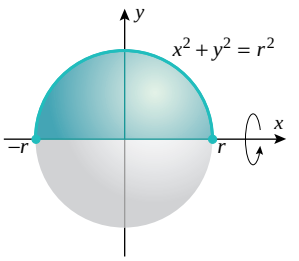


▲ Figure 6.2.10

▶ **Example 2** Find the volume of the solid that is obtained when the region under the curve $y = \sqrt{x}$ over the interval $[1, 4]$ is revolved about the $x$-axis (Figure 6.2.10).

***Solution.*** From (5), the volume is

$$V = \int_a^b \pi[f(x)]^2\,dx = \int_1^4 \pi x\,dx = \frac{\pi x^2}{2}\Big]_1^4 = 8\pi - \frac{\pi}{2} = \frac{15\pi}{2} \quad \blacktriangleleft$$



▲ Figure 6.2.11

▶ **Example 3** Derive the formula for the volume of a sphere of radius $r$.

***Solution.*** As indicated in Figure 6.2.11, a sphere of radius $r$ can be generated by revolving the upper semicircular disk enclosed between the $x$-axis and

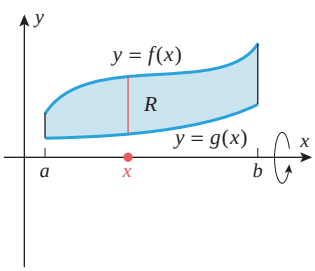
$$x^2 + y^2 = r^2$$

about the $x$-axis. Since the upper half of this circle is the graph of $y = f(x) = \sqrt{r^2 - x^2}$, it follows from (5) that the volume of the sphere is

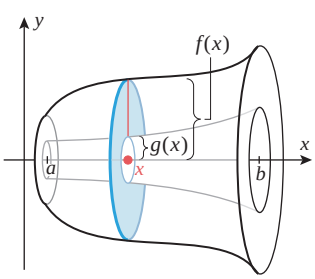
$$V = \int_a^b \pi[f(x)]^2\,dx = \int_{-r}^r \pi(r^2 - x^2)\,dx = \pi\left[r^2x - \frac{x^3}{3}\right]_{-r}^r = \frac{4}{3}\pi r^3 \quad \blacktriangleleft$$

## VOLUMES BY WASHERS PERPENDICULAR TO THE *x*-AXIS

Not all solids of revolution have solid interiors; some have holes or channels that create interior surfaces, as in Figure 6.2.8*d*. So we will also be interested in problems of the following type.



(*a*)



(*b*)

▲ Figure 6.2.12

**6.2.5 PROBLEM** Let $f$ and $g$ be continuous and nonnegative on $[a, b]$, and suppose that $f(x) \geq g(x)$ for all $x$ in the interval $[a, b]$. Let $R$ be the region that is bounded above by $y = f(x)$, below by $y = g(x)$, and on the sides by the lines $x = a$ and $x = b$ (Figure 6.2.12*a*). Find the volume of the solid of revolution that is generated by revolving the region $R$ about the $x$-axis (Figure 6.2.12*b*).

We can solve this problem by slicing. For this purpose, observe that the cross section of the solid taken perpendicular to the $x$-axis at the point $x$ is the annular or "washer-shaped"

region with inner radius $g(x)$ and outer radius $f(x)$ (Figure 6.2.12*b*); its area is

$$A(x) = \pi[f(x)]^2 - \pi[g(x)]^2 = \pi([f(x)]^2 - [g(x)]^2)$$

Thus, from (3) the volume of the solid is

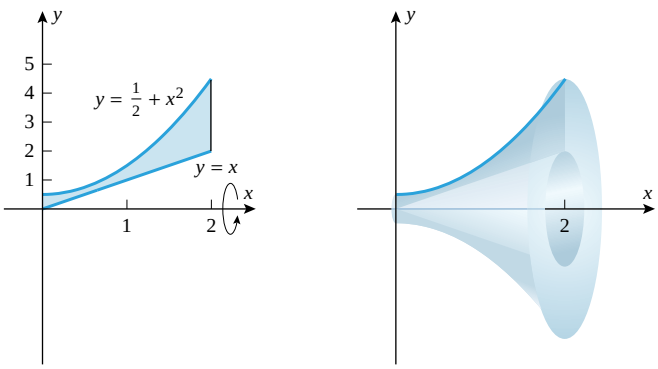
$$V = \int_a^b \pi([f(x)]^2 - [g(x)]^2)\,dx \tag{6}$$

Because the cross sections are washer shaped, the application of this formula is called the ***method of washers***.

▶ **Example 4** Find the volume of the solid generated when the region between the graphs of the equations $f(x) = \frac{1}{2} + x^2$ and $g(x) = x$ over the interval $[0, 2]$ is revolved about the $x$-axis.

***Solution.*** First sketch the region (Figure 6.2.13*a*); then imagine revolving it about the $x$-axis (Figure 6.2.13*b*). From (6) the volume is

$$V = \int_a^b \pi([f(x)]^2 - [g(x)]^2)\,dx = \int_0^2 \pi\left(\left[\tfrac{1}{2} + x^2\right]^2 - x^2\right)dx$$
$$= \int_0^2 \pi\left(\frac{1}{4} + x^4\right)dx = \pi\left[\frac{x}{4} + \frac{x^5}{5}\right]_0^2 = \frac{69\pi}{10} \quad \blacktriangleleft$$



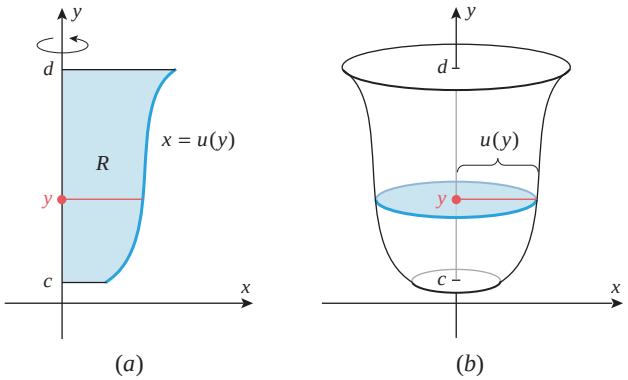
▶ **Figure 6.2.13** (*a*) (*b*)

## VOLUMES BY DISKS AND WASHERS PERPENDICULAR TO THE *y*-AXIS

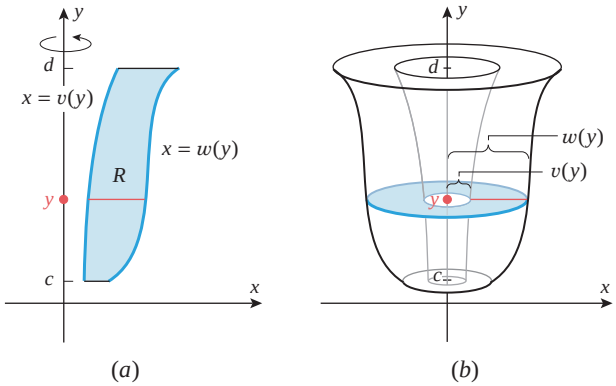
The methods of disks and washers have analogs for regions that are revolved about the $y$-axis (Figures 6.2.14 and 6.2.15). Using the method of slicing and Formula (4), you should be able to deduce the following formulas for the volumes of the solids in the figures.

$$V = \int_c^d \pi[u(y)]^2\,dy \qquad V = \int_c^d \pi([w(y)]^2 - [v(y)]^2)\,dy \tag{7–8}$$

Disks Washers



▲ Figure 6.2.14

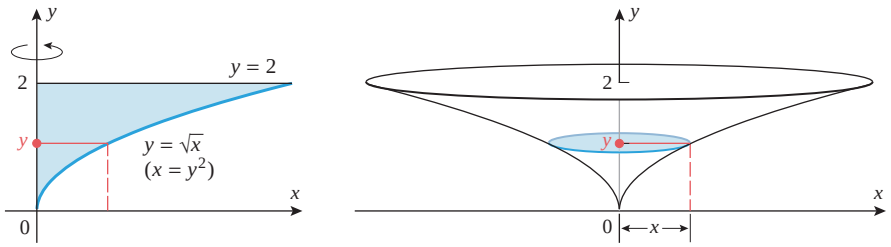


▲ Figure 6.2.15

► **Example 5** Find the volume of the solid generated when the region enclosed by $y = \sqrt{x}$, $y = 2$, and $x = 0$ is revolved about the $y$-axis.

***Solution.*** First sketch the region and the solid (Figure 6.2.16). The cross sections taken perpendicular to the $y$-axis are disks, so we will apply (7). But first we must rewrite $y = \sqrt{x}$ as $x = y^2$. Thus, from (7) with $u(y) = y^2$, the volume is

$$V = \int_c^d \pi[u(y)]^2\,dy = \int_0^2 \pi y^4\,dy = \frac{\pi y^5}{5}\Big]_0^2 = \frac{32\pi}{5} \quad \blacktriangleleft$$



► Figure 6.2.16

## OTHER AXES OF REVOLUTION

It is possible to use the method of disks and the method of washers to find the volume of a solid of revolution whose axis of revolution is a line other than one of the coordinate axes. Instead of developing a new formula for each situation, we will appeal to Formulas (3) and (4) and integrate an appropriate cross-sectional area to find the volume.

► **Example 6** Find the volume of the solid generated when the region under the curve $y = x^2$ over the interval $[0, 2]$ is rotated about the line $y = -1$.

***Solution.*** First sketch the region and the axis of revolution; then imagine revolving the region about the axis (Figure 6.2.17). At each $x$ in the interval $0 \le x \le 2$, the cross section of the solid perpendicular to the axis $y = -1$ is a washer with outer radius $x^2 + 1$ and inner radius 1. Since the area of this washer is

$$A(x) = \pi([x^2 + 1]^2 - 1^2) = \pi(x^4 + 2x^2)$$

it follows by (3) that the volume of the solid is

$$V = \int_0^2 A(x)\,dx = \int_0^2 \pi\left(x^4 + 2x^2\right)dx = \pi\left[\frac{1}{5}x^5 + \frac{2}{3}x^3\right]_0^2 = \frac{176\pi}{15} \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 6.2 *(See page 431 for answers.)*

**1.** A solid $S$ extends along the $x$-axis from $x = 1$ to $x = 3$. For $x$ between 1 and 3, the cross-sectional area of $S$ perpendicular to the $x$-axis is $3x^2$. An integral expression for the volume of $S$ is _____. The value of this integral is _____.

**2.** A solid $S$ is generated by revolving the region between the $x$-axis and the curve $y = \sqrt{\sin x}$ $(0 \le x \le \pi)$ about the $x$-axis.
(a) For $x$ between 0 and $\pi$, the cross-sectional area of $S$ perpendicular to the $x$-axis at $x$ is $A(x) =$ _____.
(b) An integral expression for the volume of $S$ is _____.
(c) The value of the integral in part (b) is _____.

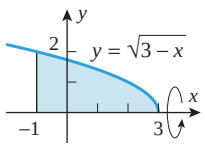
**3.** A solid $S$ is generated by revolving the region enclosed by the line $y = 2x + 1$ and the curve $y = x^2 + 1$ about the $x$-axis.
(a) For $x$ between _____ and _____, the cross-sectional area of $S$ perpendicular to the $x$-axis at $x$ is $A(x) =$ _____.
(b) An integral expression for the volume of $S$ is _____.

**4.** A solid $S$ is generated by revolving the region enclosed by the line $y = x + 1$ and the curve $y = x^2 + 1$ about the $y$-axis.
(a) For $y$ between _____ and _____, the cross-sectional area of $S$ perpendicular to the $y$-axis at $y$ is $A(y) =$ _____.
(b) An integral expression for the volume of $S$ is _____.

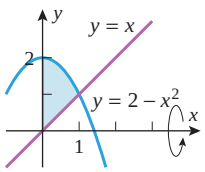
## EXERCISE SET 6.2 C CAS

**1–8** Find the volume of the solid that results when the shaded region is revolved about the indicated axis. ■

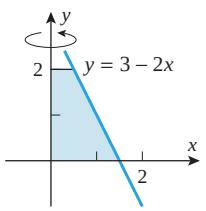
**1.**



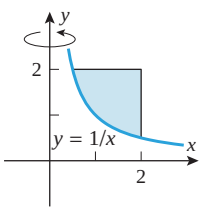
**2.**



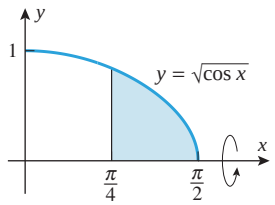
**3.**



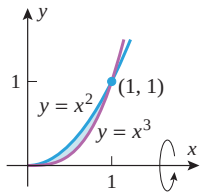
**4.**



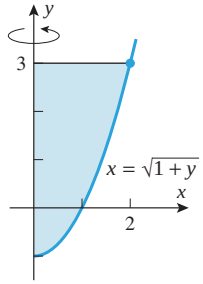
**5.**



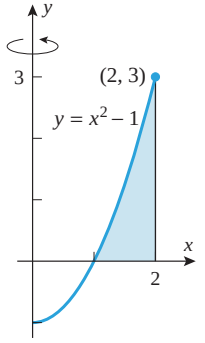
**6.**



**7.**



**8.**



**9.** Find the volume of the solid whose base is the region bounded between the curve $y = x^2$ and the $x$-axis from $x = 0$ to $x = 2$ and whose cross sections taken perpendicular to the $x$-axis are squares.

**10.** Find the volume of the solid whose base is the region bounded between the curve $y = \sec x$ and the $x$-axis from $x = \pi/4$ to $x = \pi/3$ and whose cross sections taken perpendicular to the $x$-axis are squares.

**11–18** Find the volume of the solid that results when the region enclosed by the given curves is revolved about the $x$-axis. ■

**11.** $y = \sqrt{25 - x^2},\ y = 3$

**12.** $y = 9 - x^2,\ y = 0$

**13.** $x = \sqrt{y},\ x = y/4$

**14.** $y = \sin x,\ y = \cos x,\ x = 0,\ x = \pi/4$
[*Hint:* Use the identity $\cos 2x = \cos^2 x - \sin^2 x$.]

**15.** $y = e^x,\ y = 0,\ x = 0,\ x = \ln 3$

**16.** $y = e^{-2x},\ y = 0,\ x = 0,\ x = 1$

**17.** $y = \dfrac{1}{\sqrt{4 + x^2}},\ x = -2,\ x = 2,\ y = 0$

**18.** $y = \dfrac{e^{3x}}{\sqrt{1 + e^{6x}}},\ x = 0,\ x = 1,\ y = 0$

**19.** Find the volume of the solid whose base is the region bounded between the curve $y = x^3$ and the $y$-axis from $y = 0$ to $y = 1$ and whose cross sections taken perpendicular to the $y$-axis are squares.

**20.** Find the volume of the solid whose base is the region enclosed between the curve $x = 1 - y^2$ and the $y$-axis and whose cross sections taken perpendicular to the $y$-axis are squares.

**21–26** Find the volume of the solid that results when the region enclosed by the given curves is revolved about the $y$-axis. ■

**21.** $x = \csc y,\ y = \pi/4,\ y = 3\pi/4,\ x = 0$

**22.** $y = x^2,\ x = y^2$

**23.** $x = y^2,\ x = y + 2$

**24.** $x = 1 - y^2,\ x = 2 + y^2,\ y = -1,\ y = 1$

**25.** $y = \ln x,\ x = 0,\ y = 0,\ y = 1$

**26.** $y = \sqrt{\dfrac{1 - x^2}{x^2}}\quad (x > 0),\ x = 0,\ y = 0,\ y = 2$

**27–30 True–False** Determine whether the statement is true or false. Explain your answer. [In these exercises, assume that a solid $S$ of volume $V$ is bounded by two parallel planes perpendicular to the $x$-axis at $x = a$ and $x = b$ and that for each $x$ in $[a, b]$, $A(x)$ denotes the cross-sectional area of $S$ perpendicular to the $x$-axis.] ■

**27.** If each cross section of $S$ perpendicular to the $x$-axis is a square, then $S$ is a rectangular parallelepiped (i.e., is box shaped).

**28.** If each cross section of $S$ is a disk or a washer, then $S$ is a solid of revolution.

**29.** If $x$ is in centimeters (cm), then $A(x)$ must be a quadratic function of $x$, since units of $A(x)$ will be square centimeters ($\text{cm}^2$).

**30.** The average value of $A(x)$ on the interval $[a, b]$ is given by $V/(b - a)$.

**31.** Find the volume of the solid that results when the region above the $x$-axis and below the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \quad (a > 0, b > 0)$$

is revolved about the $x$-axis.

**32.** Let $V$ be the volume of the solid that results when the region enclosed by $y = 1/x$, $y = 0$, $x = 2$, and $x = b$ $(0 < b < 2)$ is revolved about the $x$-axis. Find the value of $b$ for which $V = 3$.

**33.** Find the volume of the solid generated when the region enclosed by $y = \sqrt{x + 1}$, $y = \sqrt{2x}$, and $y = 0$ is revolved about the $x$-axis. [*Hint:* Split the solid into two parts.]

**34.** Find the volume of the solid generated when the region enclosed by $y = \sqrt{x}$, $y = 6 - x$, and $y = 0$ is revolved about the $x$-axis. [*Hint:* Split the solid into two parts.]

## FOCUS ON CONCEPTS

**35.** Suppose that $f$ is a continuous function on $[a, b]$, and let $R$ be the region between the curve $y = f(x)$ and the line $y = k$ from $x = a$ to $x = b$. Using the method of disks, derive with explanation a formula for the volume of a solid generated by revolving $R$ about the line $y = k$. State and explain additional assumptions, if any, that you need about $f$ for your formula.

**36.** Suppose that $v$ and $w$ are continuous functions on $[c, d]$, and let $R$ be the region between the curves $x = v(y)$ and $x = w(y)$ from $y = c$ to $y = d$. Using the method of washers, derive with explanation a formula for the volume of a solid generated by revolving $R$ about the line

$x = k$. State and explain additional assumptions, if any, that you need about $v$ and $w$ for your formula.

**37.** Consider the solid generated by revolving the shaded region in Exercise 1 about the line $y = 2$.
(a) Make a conjecture as to which is larger: the volume of this solid or the volume of the solid in Exercise 1. Explain the basis of your conjecture.
(b) Check your conjecture by calculating this volume and comparing it to the volume obtained in Exercise 1.

**38.** Consider the solid generated by revolving the shaded region in Exercise 4 about the line $x = 2.5$.
(a) Make a conjecture as to which is larger: the volume of this solid or the volume of the solid in Exercise 4. Explain the basis of your conjecture.
(b) Check your conjecture by calculating this volume and comparing it to the volume obtained in Exercise 4.

**39.** Find the volume of the solid that results when the region enclosed by $y = \sqrt{x}$, $y = 0$, and $x = 9$ is revolved about the line $x = 9$.

**40.** Find the volume of the solid that results when the region in Exercise 39 is revolved about the line $y = 3$.

**41.** Find the volume of the solid that results when the region enclosed by $x = y^2$ and $x = y$ is revolved about the line $y = -1$.

**42.** Find the volume of the solid that results when the region in Exercise 41 is revolved about the line $x = -1$.

**43.** Find the volume of the solid that results when the region enclosed by $y = x^2$ and $y = x^3$ is revolved about the line $x = 1$.

**44.** Find the volume of the solid that results when the region in Exercise 43 is revolved about the line $y = -1$.

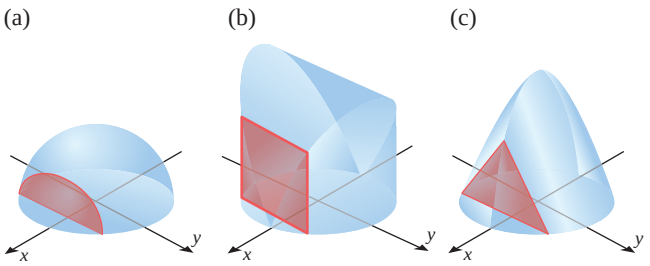
**45.** A nose cone for a space reentry vehicle is designed so that a cross section, taken $x$ ft from the tip and perpendicular to the axis of symmetry, is a circle of radius $\frac{1}{4}x^2$ ft. Find the volume of the nose cone given that its length is 20 ft.

**46.** A certain solid is 1 ft high, and a horizontal cross section taken $x$ ft above the bottom of the solid is an annulus of inner radius $x^2$ ft and outer radius $\sqrt{x}$ ft. Find the volume of the solid.

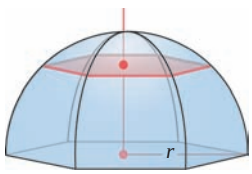
**47.** Find the volume of the solid whose base is the region bounded between the curves $y = x$ and $y = x^2$, and whose cross sections perpendicular to the $x$-axis are squares.

**48.** The base of a certain solid is the region enclosed by $y = \sqrt{x}$, $y = 0$, and $x = 4$. Every cross section perpendicular to the $x$-axis is a semicircle with its diameter across the base. Find the volume of the solid.

**49.** In parts (a)–(c) find the volume of the solid whose base is enclosed by the circle $x^2 + y^2 = 1$ and whose cross sections taken perpendicular to the $x$-axis are
(a) semicircles (b) squares
(c) equilateral triangles.



**50.** As shown in the accompanying figure, a cathedral dome is designed with three semicircular supports of radius $r$ so that each horizontal cross section is a regular hexagon. Show that the volume of the dome is $r^3\sqrt{3}$.



◀ **Figure Ex-50**

C **51–54** Use a CAS to estimate the volume of the solid that results when the region enclosed by the curves is revolved about the stated axis. ■

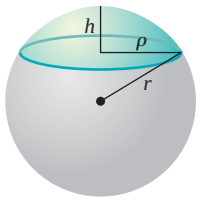
**51.** $y = \sin^8 x$, $y = 2x/\pi$, $x = 0$, $x = \pi/2$; $x$-axis

**52.** $y = \pi^2 \sin x \cos^3 x$, $y = 4x^2$, $x = 0$, $x = \pi/4$; $x$-axis

**53.** $y = e^x$, $x = 1$, $y = 1$; $y$-axis

**54.** $y = x\sqrt{\tan^{-1} x}$, $y = x$; $x$-axis

**55.** The accompanying figure shows a ***spherical cap*** of radius $\rho$ and height $h$ cut from a sphere of radius $r$. Show that the volume $V$ of the spherical cap can be expressed as
(a) $V = \frac{1}{3}\pi h^2(3r - h)$ (b) $V = \frac{1}{6}\pi h(3\rho^2 + h^2)$.



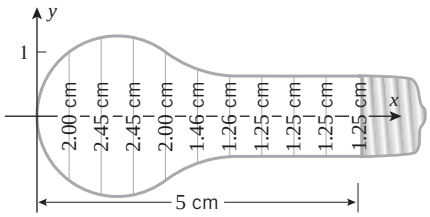
◀ **Figure Ex-55**

**56.** If fluid enters a hemispherical bowl with a radius of 10 ft at a rate of $\frac{1}{2}$ ft$^3$/min, how fast will the fluid be rising when the depth is 5 ft? [*Hint:* See Exercise 55.]

**57.** The accompanying figure (on the next page) shows the dimensions of a small lightbulb at 10 equally spaced points.
(a) Use formulas from geometry to make a rough estimate of the volume enclosed by the glass portion of the bulb.

(cont.)

(b) Use the average of left and right endpoint approximations to approximate the volume.



▲ **Figure Ex-57**

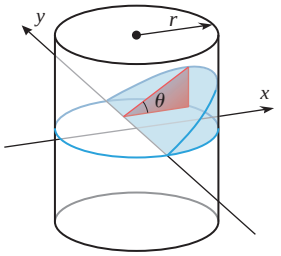
**58.** Use the result in Exercise 55 to find the volume of the solid that remains when a hole of radius $r/2$ is drilled through the center of a sphere of radius $r$, and then check your answer by integrating.

**59.** As shown in the accompanying figure, a cocktail glass with a bowl shaped like a hemisphere of diameter 8 cm contains a cherry with a diameter of 2 cm. If the glass is filled to a depth of $h$ cm, what is the volume of liquid it contains? [*Hint:* First consider the case where the cherry is partially submerged, then the case where it is totally submerged.]

◀ **Figure Ex-59**

**60.** Find the volume of the torus that results when the region enclosed by the circle of radius $r$ with center at $(h, 0)$, $h > r$, is revolved about the $y$-axis. [*Hint:* Use an appropriate formula from plane geometry to help evaluate the definite integral.]

**61.** A wedge is cut from a right circular cylinder of radius $r$ by two planes, one perpendicular to the axis of the cylinder and the other making an angle $\theta$ with the first. Find the volume of the wedge by slicing perpendicular to the $y$-axis as shown in the accompanying figure.

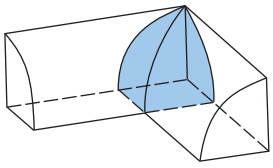


◀ **Figure Ex-61**

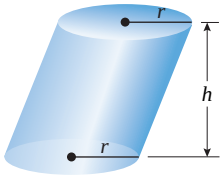
**62.** Find the volume of the wedge described in Exercise 61 by slicing perpendicular to the $x$-axis.

**63.** Two right circular cylinders of radius $r$ have axes that intersect at right angles. Find the volume of the solid common to the two cylinders. [*Hint:* One-eighth of the solid is sketched in the accompanying figure.]

**64.** In 1635 Bonaventura Cavalieri, a student of Galileo, stated the following result, called ***Cavalieri's principle***: *If two solids have the same height, and if the areas of their cross sections taken parallel to and at equal distances from their bases are always equal, then the solids have the same volume.* Use this result to find the volume of the oblique cylinder in the accompanying figure. (See Exercise 52 of Section 6.1 for a planar version of Cavalieri's principle.)



▲ **Figure Ex-63**



▲ **Figure Ex-64**

**65.** **Writing** Use the results of this section to derive Cavalieri's principle (Exercise 64).

**66.** **Writing** Write a short paragraph that explains how Formulas (4)–(8) may all be viewed as consequences of Formula (3).

## ✔ QUICK CHECK ANSWERS 6.2

**1.** $\displaystyle\int_1^3 3x^2\,dx$; 26 **2.** (a) $\pi \sin x$ (b) $\displaystyle\int_0^{\pi} \pi \sin x\,dx$ (c) $2\pi$ **3.** (a) 0; 2; $\pi[(2x+1)^2 - (x^2+1)^2] = \pi[-x^4 + 2x^2 + 4x]$ (b) $\displaystyle\int_0^2 \pi[-x^4 + 2x^2 + 4x]\,dx$ **4.** (a) 1; 2; $\pi[(y-1) - (y-1)^2] = \pi[-y^2 + 3y - 2]$ (b) $\displaystyle\int_1^2 \pi[-y^2 + 3y - 2]\,dy$

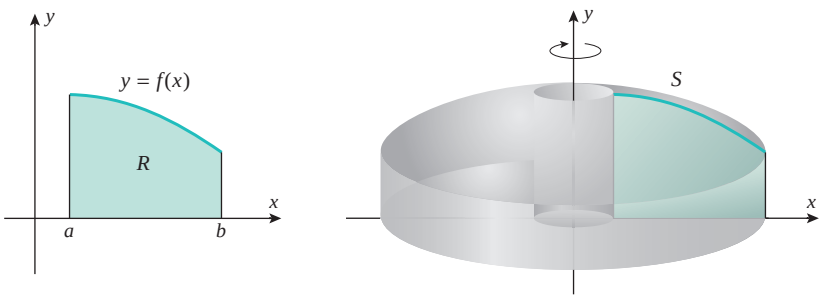
# 6.3 VOLUMES BY CYLINDRICAL SHELLS

*The methods for computing volumes that have been discussed so far depend on our ability to compute the cross-sectional area of the solid and to integrate that area across the solid. In this section we will develop another method for finding volumes that may be applicable when the cross-sectional area cannot be found or the integration is too difficult.*

## CYLINDRICAL SHELLS

In this section we will be interested in the following problem.

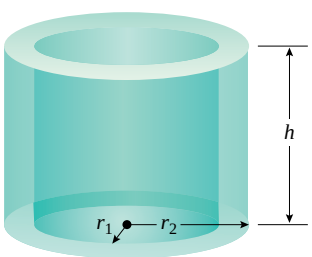
**6.3.1 PROBLEM** Let $f$ be continuous and nonnegative on $[a, b]$ $(0 \le a < b)$, and let $R$ be the region that is bounded above by $y = f(x)$, below by the $x$-axis, and on the sides by the lines $x = a$ and $x = b$. Find the volume $V$ of the solid of revolution $S$ that is generated by revolving the region $R$ about the $y$-axis (Figure 6.3.1).



▶ **Figure 6.3.1**

Sometimes problems of the above type can be solved by the method of disks or washers perpendicular to the $y$-axis, but when that method is not applicable or the resulting integral is difficult, the *method of cylindrical shells*, which we will discuss here, will often work.

A ***cylindrical shell*** is a solid enclosed by two concentric right circular cylinders (Figure 6.3.2). The volume $V$ of a cylindrical shell with inner radius $r_1$, outer radius $r_2$, and height $h$ can be written as



▲ **Figure 6.3.2**

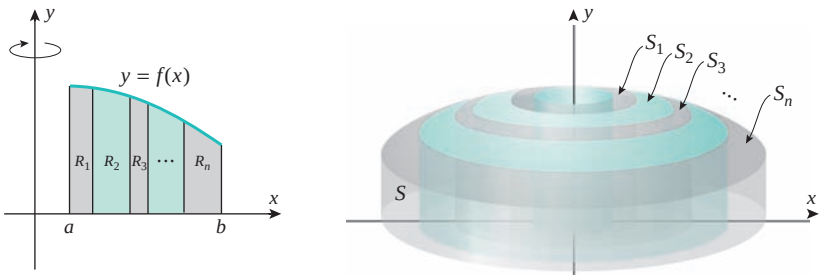
$$\begin{aligned} V &= [\text{area of cross section}] \cdot [\text{height}] \\ &= (\pi r_2^2 - \pi r_1^2)h \\ &= \pi(r_2 + r_1)(r_2 - r_1)h \\ &= 2\pi \cdot \left[\tfrac{1}{2}(r_1 + r_2)\right] \cdot h \cdot (r_2 - r_1) \end{aligned}$$

But $\frac{1}{2}(r_1 + r_2)$ is the average radius of the shell and $r_2 - r_1$ is its thickness, so

$$V = 2\pi \cdot [\text{average radius}] \cdot [\text{height}] \cdot [\text{thickness}] \qquad (1)$$

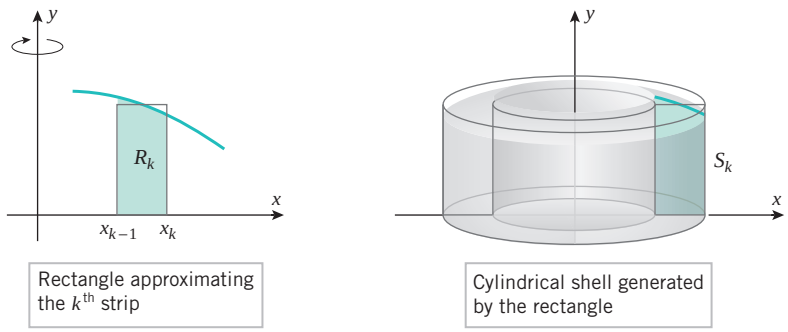
We will now show how this formula can be used to solve Problem 6.3.1. The underlying idea is to divide the interval $[a, b]$ into $n$ subintervals, thereby subdividing the region $R$ into $n$ strips, $R_1, R_2, \ldots, R_n$ (Figure 6.3.3*a*). When the region $R$ is revolved about the $y$-axis, these strips generate "tube-like" solids $S_1, S_2, \ldots, S_n$ that are nested one inside the other and together comprise the entire solid $S$ (Figure 6.3.3*b*). Thus, the volume $V$ of the solid can be obtained by adding together the volumes of the tubes; that is,

$$V = V(S_1) + V(S_2) + \cdots + V(S_n)$$



▶ **Figure 6.3.3**

As a rule, the tubes will have curved upper surfaces, so there will be no simple formulas for their volumes. However, if the strips are thin, then we can approximate each strip by a rectangle (Figure 6.3.4*a*). These rectangles, when revolved about the $y$-axis, will produce cylindrical shells whose volumes closely approximate the volumes of the tubes generated by the original strips (Figure 6.3.4*b*). We will show that by adding the volumes of the cylindrical shells we can obtain a Riemann sum that approximates the volume $V$, and by taking the limit of the Riemann sums we can obtain an integral for the exact volume $V$.



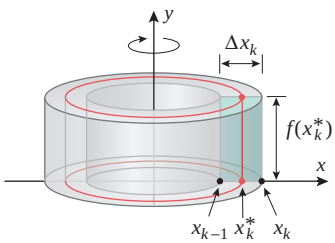
▶ **Figure 6.3.4**

To implement this idea, suppose that the $k$th strip extends from $x_{k-1}$ to $x_k$ and that the width of this strip is

$$\Delta x_k = x_k - x_{k-1}$$

If we let $x_k^*$ be the *midpoint* of the interval $[x_{k-1}, x_k]$, and if we construct a rectangle of height $f(x_k^*)$ over the interval, then revolving this rectangle about the $y$-axis produces a cylindrical shell of average radius $x_k^*$, height $f(x_k^*)$, and thickness $\Delta x_k$ (Figure 6.3.5). From (1), the volume $V_k$ of this cylindrical shell is

$$V_k = 2\pi x_k^* f(x_k^*) \Delta x_k$$



▲ **Figure 6.3.5**

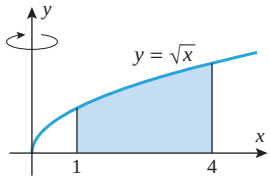
Adding the volumes of the $n$ cylindrical shells yields the following Riemann sum that approximates the volume $V$:

$$V \approx \sum_{k=1}^{n} 2\pi x_k^* f(x_k^*) \Delta x_k$$

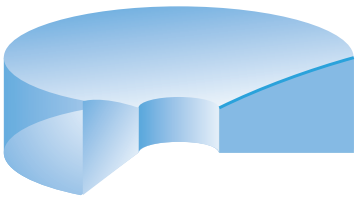
Taking the limit as $n$ increases and the widths of all the subintervals approach zero yields the definite integral

$$V = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} 2\pi x_k^* f(x_k^*) \Delta x_k = \int_a^b 2\pi x f(x)\, dx$$

In summary, we have the following result.



(a)



Cutaway view of the solid

(b)

▲ Figure 6.3.6

**6.3.2 VOLUME BY CYLINDRICAL SHELLS ABOUT THE $y$-AXIS** Let $f$ be continuous and nonnegative on $[a, b]$ $(0 \le a < b)$, and let $R$ be the region that is bounded above by $y = f(x)$, below by the $x$-axis, and on the sides by the lines $x = a$ and $x = b$. Then the volume $V$ of the solid of revolution that is generated by revolving the region $R$ about the $y$-axis is given by

$$V = \int_a^b 2\pi x f(x)\,dx \tag{2}$$

▶ **Example 1** Use cylindrical shells to find the volume of the solid generated when the region enclosed between $y = \sqrt{x}$, $x = 1$, $x = 4$, and the $x$-axis is revolved about the $y$-axis.

***Solution.*** First sketch the region (Figure 6.3.6*a*); then imagine revolving it about the $y$-axis (Figure 6.3.6*b*). Since $f(x) = \sqrt{x}$, $a = 1$, and $b = 4$, Formula (2) yields

$$V = \int_1^4 2\pi x\sqrt{x}\,dx = 2\pi \int_1^4 x^{3/2}\,dx = \left[2\pi \cdot \frac{2}{5}x^{5/2}\right]_1^4 = \frac{4\pi}{5}[32 - 1] = \frac{124\pi}{5} \quad \blacktriangleleft$$

## VARIATIONS OF THE METHOD OF CYLINDRICAL SHELLS

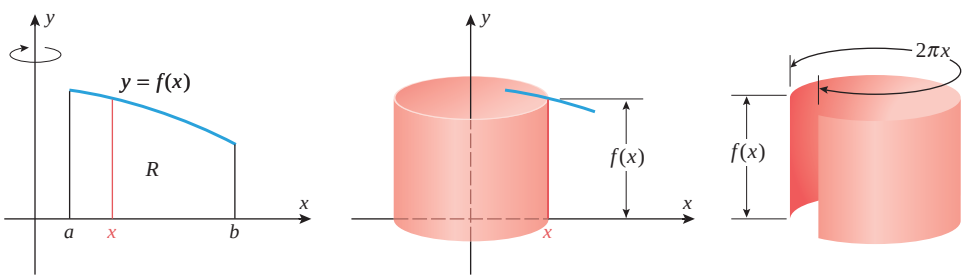
The method of cylindrical shells is applicable in a variety of situations that do not fit the conditions required by Formula (2). For example, the region may be enclosed between two curves, or the axis of revolution may be some line other than the $y$-axis. However, rather than develop a separate formula for every possible situation, we will give a general way of thinking about the method of cylindrical shells that can be adapted to each new situation as it arises.

For this purpose, we will need to reexamine the integrand in Formula (2): At each $x$ in the interval $[a, b]$, the vertical line segment from the $x$-axis to the curve $y = f(x)$ can be viewed as the cross section of the region $R$ at $x$ (Figure 6.3.7*a*). When the region $R$ is revolved about the $y$-axis, the cross section at $x$ sweeps out the *surface* of a right circular cylinder of height $f(x)$ and radius $x$ (Figure 6.3.7*b*). The area of this surface is

$$2\pi x f(x)$$

(Figure 6.3.7*c*), which is the integrand in (2). Thus, Formula (2) can be viewed informally in the following way.

**6.3.3 AN INFORMAL VIEWPOINT ABOUT CYLINDRICAL SHELLS** The volume $V$ of a solid of revolution that is generated by revolving a region $R$ about an axis can be obtained by integrating the area of the surface generated by an arbitrary cross section of $R$ taken parallel to the axis of revolution.



▶ Figure 6.3.7

(a) (b) (c)

The following examples illustrate how to apply this result in situations where Formula (2) is not applicable.

▶ **Example 2** Use cylindrical shells to find the volume of the solid generated when the region $R$ in the first quadrant enclosed between $y = x$ and $y = x^2$ is revolved about the $y$-axis (Figure 6.3.8*a*).

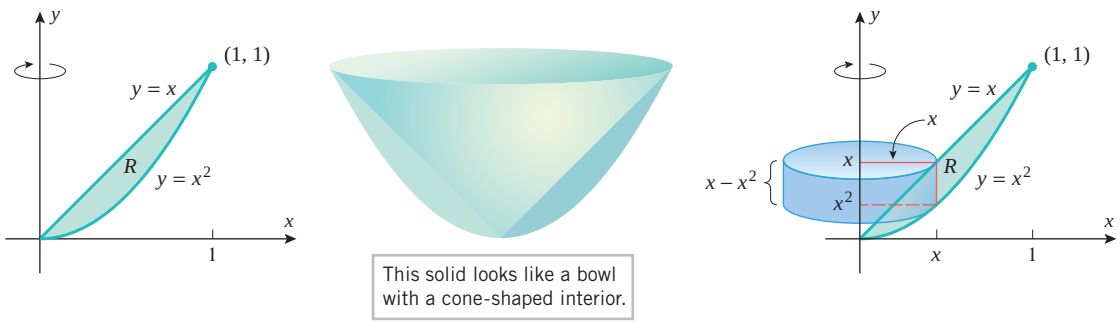
***Solution.*** As illustrated in part (*b*) of Figure 6.3.8, at each $x$ in $[0, 1]$ the cross section of $R$ parallel to the $y$-axis generates a cylindrical surface of height $x - x^2$ and radius $x$. Since the area of this surface is

$$2\pi x(x - x^2)$$

the volume of the solid is

$$V = \int_0^1 2\pi x(x - x^2)\,dx = 2\pi \int_0^1 (x^2 - x^3)\,dx$$

$$= 2\pi \left[\frac{x^3}{3} - \frac{x^4}{4}\right]_0^1 = 2\pi \left[\frac{1}{3} - \frac{1}{4}\right] = \frac{\pi}{6} \quad \blacktriangleleft$$



▲ **Figure 6.3.8**

▶ **Example 3** Use cylindrical shells to find the volume of the solid generated when the region $R$ under $y = x^2$ over the interval $[0, 2]$ is revolved about the line $y = -1$.

***Solution.*** First draw the axis of revolution; then imagine revolving the region about the axis (Figure 6.3.9*a*). As illustrated in Figure 6.3.9*b*, at each $y$ in the interval $0 \le y \le 4$, the cross section of $R$ parallel to the $x$-axis generates a cylindrical surface of height $2 - \sqrt{y}$ and radius $y + 1$. Since the area of this surface is

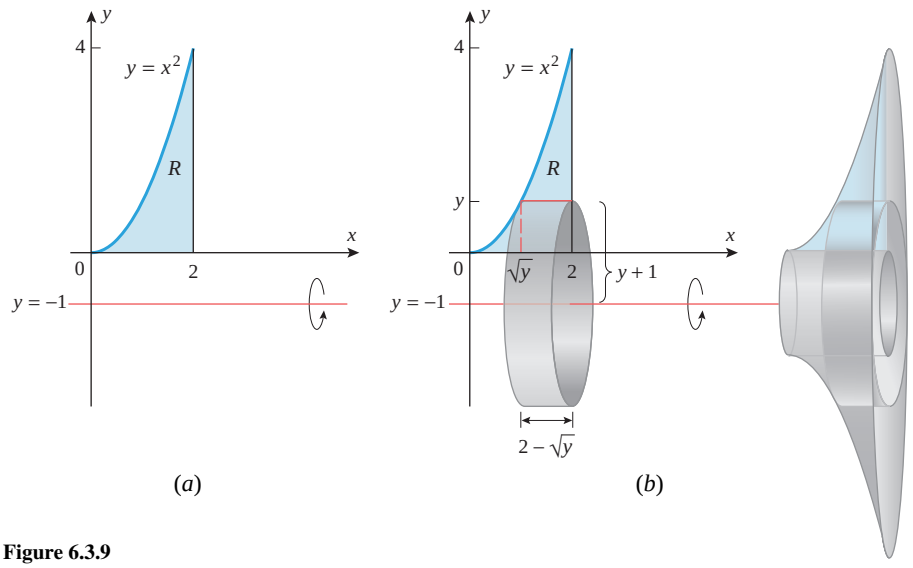
$$2\pi(y + 1)(2 - \sqrt{y})$$

it follows that the volume of the solid is

$$\int_0^4 2\pi(y + 1)(2 - \sqrt{y})\,dy = 2\pi \int_0^4 (2y - y^{3/2} + 2 - y^{1/2})\,dy$$

$$= 2\pi \left[y^2 - \frac{2}{5}y^{5/2} + 2y - \frac{2}{3}y^{3/2}\right]_0^4 = \frac{176\pi}{15} \quad \blacktriangleleft$$

Note that the volume found in Example 3 agrees with the volume of the same solid found by the method of washers in Example 6 of Section 6.2. Confirm that the volume in Example 2 found by the method of cylindrical shells can also be obtained by the method of washers.



▶ **Figure 6.3.9**

## ✔ QUICK CHECK EXERCISES 6.3 *(See page 438 for answers.)*

**1.** Let $R$ be the region between the $x$-axis and the curve $y = 1 + \sqrt{x}$ for $1 \le x \le 4$.

(a) For $x$ between 1 and 4, the area of the cylindrical surface generated by revolving the vertical cross section of $R$ at $x$ about the $y$-axis is _____.

(b) Using cylindrical shells, an integral expression for the volume of the solid generated by revolving $R$ about the $y$-axis is _____.

**2.** Let $R$ be the region described in Quick Check Exercise 1.

(a) For $x$ between 1 and 4, the area of the cylindrical surface generated by revolving the vertical cross section of $R$ at $x$ about the line $x = 5$ is _____.

(b) Using cylindrical shells, an integral expression for the volume of the solid generated by revolving $R$ about the line $x = 5$ is _____.

**3.** A solid $S$ is generated by revolving the region enclosed by the curves $x = (y - 2)^2$ and $x = 4$ about the $x$-axis. Using cylindrical shells, an integral expression for the volume of $S$ is _____.

## EXERCISE SET 6.3 C CAS

**13.** $y^2 = x,\ y = 1,\ x = 0$

**14.** $x = 2y,\ y = 2,\ y = 3,\ x = 0$

**15.** $y = x^2,\ x = 1,\ y = 0$ **16.** $xy = 4,\ x + y = 5$

**17–20 True–False** Determine whether the statement is true or false. Explain your answer. ■

**17.** The volume of a cylindrical shell is equal to the product of the thickness of the shell with the surface area of a cylinder whose height is that of the shell and whose radius is equal to the average of the inner and outer radii of the shell.

**18.** The method of cylindrical shells is a special case of the method of integration of cross-sectional area that was discussed in Section 6.2.

**19.** In the method of cylindrical shells, integration is over an interval on a coordinate axis that is *perpendicular* to the axis of revolution of the solid.

**20.** The Riemann sum approximation

$$V \approx \sum_{k=1}^{n} 2\pi x_k^* f(x_k^*)\Delta x_k \quad \left(\text{where } x_k^* = \frac{x_k + x_{k-1}}{2}\right)$$

for the volume of a solid of revolution is exact when $f$ is a constant function.

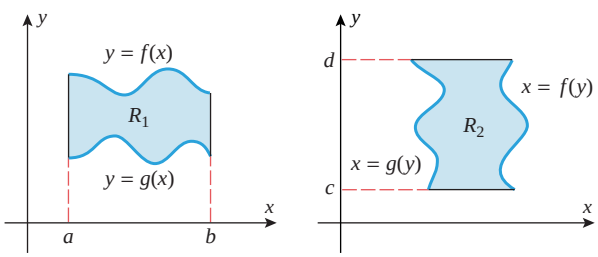
C **21.** Use a CAS to find the volume of the solid generated when the region enclosed by $y = e^x$ and $y = 0$ for $1 \le x \le 2$ is revolved about the $y$-axis.

C **22.** Use a CAS to find the volume of the solid generated when the region enclosed by $y = \cos x$, $y = 0$, and $x = 0$ for $0 \le x \le \pi/2$ is revolved about the $y$-axis.

C **23.** Consider the region to the right of the $y$-axis, to the left of the vertical line $x = k$ $(0 < k < \pi)$, and between the curve $y = \sin x$ and the $x$-axis. Use a CAS to estimate the value of $k$ so that the solid generated by revolving the region about the $y$-axis has a volume of 8 cubic units.

**FOCUS ON CONCEPTS**

**24.** Let $R_1$ and $R_2$ be regions of the form shown in the accompanying figure. Use cylindrical shells to find a formula for the volume of the solid that results when
(a) region $R_1$ is revolved about the $y$-axis
(b) region $R_2$ is revolved about the $x$-axis.



▲ Figure Ex-24

**25.** (a) Use cylindrical shells to find the volume of the solid that is generated when the region under the curve

$$y = x^3 - 3x^2 + 2x$$

over $[0, 1]$ is revolved about the $y$-axis.
(b) For this problem, is the method of cylindrical shells easier or harder than the method of slicing discussed in the last section? Explain.

**26.** Let $f$ be continuous and nonnegative on $[a, b]$, and let $R$ be the region that is enclosed by $y = f(x)$ and $y = 0$ for $a \le x \le b$. Using the method of cylindrical shells, derive with explanation a formula for the volume of the solid generated by revolving $R$ about the line $x = k$, where $k \le a$.

**27–28** Using the method of cylindrical shells, set up but do not evaluate an integral for the volume of the solid generated when the region $R$ is revolved about (a) the line $x = 1$ and (b) the line $y = -1$. ■

**27.** $R$ is the region bounded by the graphs of $y = x$, $y = 0$, and $x = 1$.

**28.** $R$ is the region in the first quadrant bounded by the graphs of $y = \sqrt{1 - x^2}$, $y = 0$, and $x = 0$.

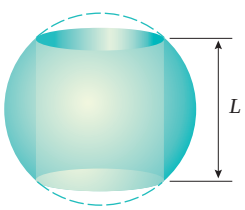
**29.** Use cylindrical shells to find the volume of the solid that is generated when the region that is enclosed by $y = 1/x^3$, $x = 1$, $x = 2$, $y = 0$ is revolved about the line $x = -1$.

**30.** Use cylindrical shells to find the volume of the solid that is generated when the region that is enclosed by $y = x^3$, $y = 1$, $x = 0$ is revolved about the line $y = 1$.

**31.** Use cylindrical shells to find the volume of the cone generated when the triangle with vertices $(0, 0)$, $(0, r)$, $(h, 0)$, where $r > 0$ and $h > 0$, is revolved about the $x$-axis.

**32.** The region enclosed between the curve $y^2 = kx$ and the line $x = \frac{1}{4}k$ is revolved about the line $x = \frac{1}{2}k$. Use cylindrical shells to find the volume of the resulting solid. (Assume $k > 0$.)

**33.** As shown in the accompanying figure, a cylindrical hole is drilled all the way through the center of a sphere. Show that the volume of the remaining solid depends only on the length $L$ of the hole, not on the size of the sphere.



◀ Figure Ex-33

**34.** Use cylindrical shells to find the volume of the torus obtained by revolving the circle $x^2 + y^2 = a^2$ about the line

$x = b$, where $b > a > 0$. [*Hint:* It may help in the integration to think of an integral as an area.]

**35.** Let $V_x$ and $V_y$ be the volumes of the solids that result when the region enclosed by $y = 1/x$, $y = 0$, $x = \frac{1}{2}$, and $x = b$ $\left(b > \frac{1}{2}\right)$ is revolved about the $x$-axis and $y$-axis, respectively. Is there a value of $b$ for which $V_x = V_y$?

**36.** (a) Find the volume $V$ of the solid generated when the region bounded by $y = 1/(1 + x^4)$, $y = 0$, $x = 1$, and $x = b$ $(b > 1)$ is revolved about the $y$-axis.

(b) Find $\lim_{b \to +\infty} V$.

**37. Writing** Faced with the problem of computing the volume of a solid of revolution, how would you go about deciding whether to use the method of disks/washers or the method of cylindrical shells?

**38. Writing** With both the method of disks/washers and with the method of cylindrical shells, we integrate an "area" to get the volume of a solid of revolution. However, these two approaches differ in very significant ways. Write a brief paragraph that discusses these differences.

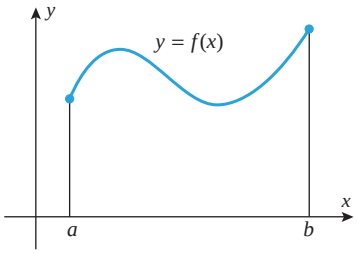
# 6.4 LENGTH OF A PLANE CURVE

*In this section we will use the tools of calculus to study the problem of finding the length of a plane curve.*



▲ **Figure 6.4.1**

Intuitively, you might think of the arc length of a curve as the number obtained by aligning a piece of string with the curve and then measuring the length of the string after it is straightened out.

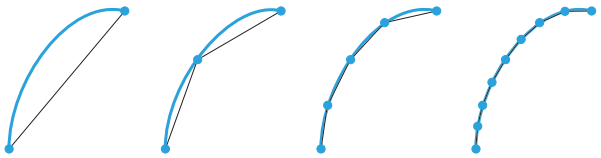
## ARC LENGTH

Our first objective is to define what we mean by the ***length*** (also called the ***arc length***) of a plane curve $y = f(x)$ over an interval $[a, b]$ (Figure 6.4.1). Once that is done we will be able to focus on the problem of computing arc lengths. To avoid some complications that would otherwise occur, we will impose the requirement that $f'$ be continuous on $[a, b]$, in which case we will say that $y = f(x)$ is a ***smooth curve*** on $[a, b]$ or that $f$ is a ***smooth function*** on $[a, b]$. Thus, we will be concerned with the following problem.

**6.4.1 ARC LENGTH PROBLEM** Suppose that $y = f(x)$ is a smooth curve on the interval $[a, b]$. Define and find a formula for the arc length $L$ of the curve $y = f(x)$ over the interval $[a, b]$.

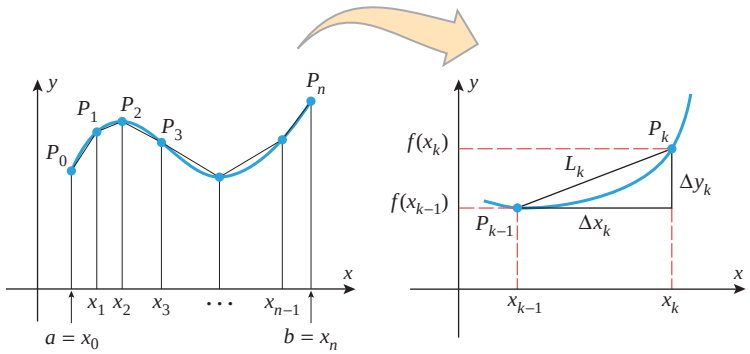
To define the arc length of a curve we start by breaking the curve into small segments. Then we approximate the curve segments by line segments and add the lengths of the line segments to form a Riemann sum. Figure 6.4.2 illustrates how such line segments tend to become better and better approximations to a curve as the number of segments increases. As the number of segments increases, the corresponding Riemann sums approach a definite integral whose value we will take to be the arc length $L$ of the curve.

To implement our idea for solving Problem 6.4.1, divide the interval $[a, b]$ into $n$ subintervals by inserting points $x_1, x_2, \ldots, x_{n-1}$ between $a = x_0$ and $b = x_n$. As shown in Figure 6.4.3*a*, let $P_0, P_1, \ldots, P_n$ be the points on the curve with $x$-coordinates $a = x_0$,



Shorter line segments provide a better approximation to the curve.

▶ **Figure 6.4.2**



▶ **Figure 6.4.3**

$x_1, x_2, \ldots, x_{n-1}, b = x_n$ and join these points with straight line segments. These line segments form a ***polygonal path*** that we can regard as an approximation to the curve $y = f(x)$. As indicated in Figure 6.4.3*b*, the length $L_k$ of the $k$th line segment in the polygonal path is

$$L_k = \sqrt{(\Delta x_k)^2 + (\Delta y_k)^2} = \sqrt{(\Delta x_k)^2 + [f(x_k) - f(x_{k-1})]^2} \tag{1}$$

If we now add the lengths of these line segments, we obtain the following approximation to the length $L$ of the curve

$$L \approx \sum_{k=1}^{n} L_k = \sum_{k=1}^{n} \sqrt{(\Delta x_k)^2 + [f(x_k) - f(x_{k-1})]^2} \tag{2}$$

To put this in the form of a Riemann sum we will apply the Mean-Value Theorem (4.8.2). This theorem implies that there is a point $x_k^*$ between $x_{k-1}$ and $x_k$ such that

$$\frac{f(x_k) - f(x_{k-1})}{x_k - x_{k-1}} = f'(x_k^*) \quad \text{or} \quad f(x_k) - f(x_{k-1}) = f'(x_k^*)\Delta x_k$$

and hence we can rewrite (2) as

$$L \approx \sum_{k=1}^{n} \sqrt{(\Delta x_k)^2 + [f'(x_k^*)]^2 (\Delta x_k)^2} = \sum_{k=1}^{n} \sqrt{1 + [f'(x_k^*)]^2}\, \Delta x_k$$

Explain why the approximation in (2) cannot be greater than $L$.

Thus, taking the limit as $n$ increases and the widths of all the subintervals approach zero yields the following integral that defines the arc length $L$:

$$L = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} \sqrt{1 + [f'(x_k^*)]^2}\, \Delta x_k = \int_a^b \sqrt{1 + [f'(x)]^2}\, dx$$

In summary, we have the following definition.

**6.4.2 DEFINITION** If $y = f(x)$ is a smooth curve on the interval $[a, b]$, then the arc length $L$ of this curve over $[a, b]$ is defined as

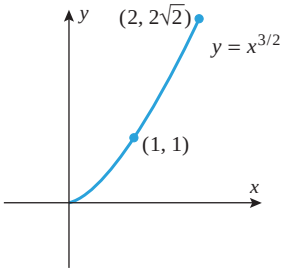
$$L = \int_a^b \sqrt{1 + [f'(x)]^2}\, dx \tag{3}$$

This result provides both a definition and a formula for computing arc lengths. Where convenient, (3) can also be expressed as

$$L = \int_a^b \sqrt{1 + [f'(x)]^2}\, dx = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx \tag{4}$$

Moreover, for a curve expressed in the form $x = g(y)$, where $g'$ is continuous on $[c, d]$, the arc length $L$ from $y = c$ to $y = d$ can be expressed as

$$L = \int_c^d \sqrt{1 + [g'(y)]^2}\, dy = \int_c^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\, dy \tag{5}$$



▲ **Figure 6.4.4**

▶ **Example 1** Find the arc length of the curve $y = x^{3/2}$ from $(1, 1)$ to $(2, 2\sqrt{2})$ (Figure 6.4.4) in two ways: (a) using Formula (4) and (b) using Formula (5).

***Solution (a).***

$$\frac{dy}{dx} = \frac{3}{2}x^{1/2}$$

and since the curve extends from $x = 1$ to $x = 2$, it follows from (4) that

$$L = \int_1^2 \sqrt{1 + \left(\tfrac{3}{2}x^{1/2}\right)^2}\, dx = \int_1^2 \sqrt{1 + \tfrac{9}{4}x}\, dx$$

To evaluate this integral we make the $u$-substitution

$$u = 1 + \tfrac{9}{4}x, \quad du = \tfrac{9}{4}\, dx$$

and then change the $x$-limits of integration ($x = 1, x = 2$) to the corresponding $u$-limits $\left(u = \frac{13}{4}, u = \frac{22}{4}\right)$:

$$L = \frac{4}{9}\int_{13/4}^{22/4} u^{1/2}\, du = \frac{8}{27}u^{3/2}\Big]_{13/4}^{22/4} = \frac{8}{27}\left[\left(\frac{22}{4}\right)^{3/2} - \left(\frac{13}{4}\right)^{3/2}\right]$$

$$= \frac{22\sqrt{22} - 13\sqrt{13}}{27} \approx 2.09$$

***Solution (b).*** To apply Formula (5) we must first rewrite the equation $y = x^{3/2}$ so that $x$ is expressed as a function of $y$. This yields $x = y^{2/3}$ and

$$\frac{dx}{dy} = \frac{2}{3}y^{-1/3}$$

Since the curve extends from $y = 1$ to $y = 2\sqrt{2}$, it follows from (5) that

$$L = \int_1^{2\sqrt{2}} \sqrt{1 + \tfrac{4}{9}y^{-2/3}}\, dy = \frac{1}{3}\int_1^{2\sqrt{2}} y^{-1/3}\sqrt{9y^{2/3} + 4}\, dy$$

To evaluate this integral we make the $u$-substitution

$$u = 9y^{2/3} + 4, \quad du = 6y^{-1/3}\,dy$$

and change the $y$-limits of integration ($y = 1$, $y = 2\sqrt{2}$) to the corresponding $u$-limits ($u = 13$, $u = 22$). This gives

$$L = \frac{1}{18}\int_{13}^{22} u^{1/2}\,du = \frac{1}{27}u^{3/2}\Big]_{13}^{22} = \frac{1}{27}[(22)^{3/2} - (13)^{3/2}] = \frac{22\sqrt{22} - 13\sqrt{13}}{27}$$

The answer in part (b) agrees with that in part (a); however, the integration in part (b) is more tedious. In problems where there is a choice between using (4) or (5), it is often the case that one of the formulas leads to a simpler integral than the other. ◀

The arc from the point $(1, 1)$ to the point $(2, 2\sqrt{2})$ in Figure 6.4.4 is nearly a straight line, so the arc length should be only slightly larger than the straight-line distance between these points. Show that this is so.

## FINDING ARC LENGTH BY NUMERICAL METHODS

In the next chapter we will develop some techniques of integration that will enable us to find exact values of more integrals encountered in arc length calculations; however, generally speaking, most such integrals are impossible to evaluate in terms of elementary functions. In these cases one usually approximates the integral using a numerical method such as the midpoint rule discussed in Section 5.4.

**TECHNOLOGY MASTERY**

If your calculating utility has a numerical integration capability, use it to confirm that the arc length $L$ in Example 2 is approximately $L \approx 3.8202$.

▶ **Example 2** From (4), the arc length of $y = \sin x$ from $x = 0$ to $x = \pi$ is given by the integral

$$L = \int_0^{\pi} \sqrt{1 + (\cos x)^2}\,dx$$

This integral cannot be evaluated in terms of elementary functions; however, using a calculating utility with a numerical integration capability yields the approximation $L \approx 3.8202$. ◀

## ✔ QUICK CHECK EXERCISES 6.4 (See page 443 for answers.)

1. A function $f$ is smooth on $[a, b]$ if $f'$ is _____ on $[a, b]$.
2. If a function $f$ is smooth on $[a, b]$, then the length of the curve $y = f(x)$ over $[a, b]$ is _____.
3. The distance between points $(1, 0)$ and $(e, 1)$ is _____.
4. Let $L$ be the length of the curve $y = \ln x$ from $(1, 0)$ to $(e, 1)$.
   (a) Integrating with respect to $x$, an integral expression for $L$ is _____.
   (b) Integrating with respect to $y$, an integral expression for $L$ is _____.

## EXERCISE SET 6.4 C CAS

1. Use the Theorem of Pythagoras to find the length of the line segment $y = 2x$ from (1, 2) to (2, 4), and confirm that the value is consistent with the length computed using
   (a) Formula (4) (b) Formula (5).
2. Use the Theorem of Pythagoras to find the length of the line segment $y = 5x$ from (0, 0) and (1, 5), and confirm that the value is consistent with the length computed using
   (a) Formula (4) (b) Formula (5).

**3–8** Find the exact arc length of the curve over the interval. ■

3. $y = 3x^{3/2} - 1$ from $x = 0$ to $x = 1$
4. $x = \frac{1}{3}(y^2 + 2)^{3/2}$ from $y = 0$ to $y = 1$
5. $y = x^{2/3}$ from $x = 1$ to $x = 8$
6. $y = (x^6 + 8)/(16x^2)$ from $x = 2$ to $x = 3$
7. $24xy = y^4 + 48$ from $y = 2$ to $y = 4$
8. $x = \frac{1}{8}y^4 + \frac{1}{4}y^{-2}$ from $y = 1$ to $y = 4$

**9–12 True–False** Determine whether the statement is true or false. Explain your answer. ■

9. The graph of $y = \sqrt{1 - x^2}$ is a smooth curve on $[-1, 1]$.

**10.** The approximation

$$L \approx \sum_{k=1}^{n} \sqrt{(\Delta x_k)^2 + [f(x_k) - f(x_{k-1})]^2}$$

for arc length is not expressed in the form of a Riemann sum.

**11.** The approximation

$$L \approx \sum_{k=1}^{n} \sqrt{1 + [f'(x_k^*)]^2}\, \Delta x_k$$

for arc length is exact when $f$ is a linear function of $x$.

**12.** In our definition of the arc length for the graph of $y = f(x)$, we need $f'(x)$ to be a continuous function in order for $f$ to satisfy the hypotheses of the Mean-Value Theorem (4.8.2).

C **13–14** Express the exact arc length of the curve over the given interval as an integral that has been simplified to eliminate the radical, and then evaluate the integral using a CAS. ■

**13.** $y = \ln(\sec x)$ from $x = 0$ to $x = \pi/4$

**14.** $y = \ln(\sin x)$ from $x = \pi/4$ to $x = \pi/2$

**FOCUS ON CONCEPTS**

**15.** Consider the curve $y = x^{2/3}$.

(a) Sketch the portion of the curve between $x = -1$ and $x = 8$.

(b) Explain why Formula (4) cannot be used to find the arc length of the curve sketched in part (a).

(c) Find the arc length of the curve sketched in part (a).

**16.** The curve segment $y = x^2$ from $x = 1$ to $x = 2$ may also be expressed as the graph of $x = \sqrt{y}$ from $y = 1$ to $y = 4$. Set up two integrals that give the arc length of this curve segment, one by integrating with respect to $x$, and the other by integrating with respect to $y$. Demonstrate a substitution that verifies that these two integrals are equal.

**17.** Consider the curve segments $y = x^2$ from $x = \frac{1}{2}$ to $x = 2$ and $y = \sqrt{x}$ from $x = \frac{1}{4}$ to $x = 4$.

(a) Graph the two curve segments and use your graphs to explain why the lengths of these two curve segments should be equal.

(b) Set up integrals that give the arc lengths of the curve segments by integrating with respect to $x$. Demonstrate a substitution that verifies that these two integrals are equal.

(c) Set up integrals that give the arc lengths of the curve segments by integrating with respect to $y$.

(d) Approximate the arc length of each curve segment using Formula (2) with $n = 10$ equal subintervals.

(e) Which of the two approximations in part (d) is more accurate? Explain.

(f) Use the midpoint approximation with $n = 10$ subintervals to approximate each arc length integral in part (b).

(g) Use a calculating utility with numerical integration capabilities to approximate the arc length integrals in part (b) to four decimal places.

**18.** Follow the directions of Exercise 17 for the curve segments $y = x^{8/3}$ from $x = 10^{-3}$ to $x = 1$ and $y = x^{3/8}$ from $x = 10^{-8}$ to $x = 1$.

**19.** Follow the directions of Exercise 17 for the curve segment $y = \tan x$ from $x = 0$ to $x = \pi/3$ and for the curve segment $y = \tan^{-1} x$ from $x = 0$ to $x = \sqrt{3}$.

**20.** Let $y = f(x)$ be a smooth curve on the closed interval $[a, b]$. Prove that if $m$ and $M$ are nonnegative numbers such that $m \le |f'(x)| \le M$ for all $x$ in $[a, b]$, then the arc length $L$ of $y = f(x)$ over the interval $[a, b]$ satisfies the inequalities

$$(b - a)\sqrt{1 + m^2} \le L \le (b - a)\sqrt{1 + M^2}$$

**21.** Use the result of Exercise 20 to show that the arc length $L$ of $y = \sec x$ over the interval $0 \le x \le \pi/3$ satisfies

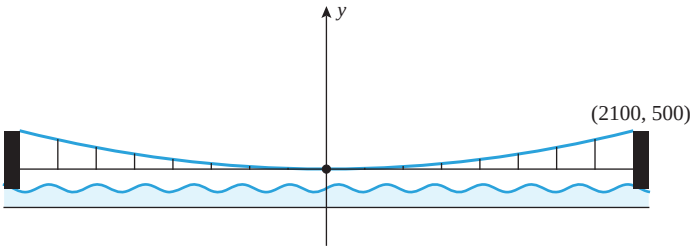
$$\frac{\pi}{3} \le L \le \frac{\pi}{3}\sqrt{13}$$

C **22.** A basketball player makes a successful shot from the free throw line. Suppose that the path of the ball from the moment of release to the moment it enters the hoop is described by

$$y = 2.15 + 2.09x - 0.41x^2, \quad 0 \le x \le 4.6$$

where $x$ is the horizontal distance (in meters) from the point of release, and $y$ is the vertical distance (in meters) above the floor. Use a CAS or a scientific calculator with a numerical integration capability to approximate the distance the ball travels from the moment it is released to the moment it enters the hoop. Round your answer to two decimal places.

C **23.** The central span of the Golden Gate Bridge in California is 4200 ft long and is suspended from cables that rise 500 ft above the roadway on either side. Approximately how long is the portion of a cable that lies between the support towers on one side of the roadway? [*Hint:* As suggested by the accompanying figure, assume the cable is modeled by a parabola $y = ax^2$ that passes through the point (2100, 500). Use a CAS or a calculating utility with a numerical integration capability to approximate the length of the cable. Round your answer to the nearest foot.]



▲ **Figure Ex-23**

C **24.** As shown in the accompanying figure, a horizontal beam with dimensions 2 in × 6 in × 16 ft is fixed at both ends and is subjected to a uniformly distributed load of 120 lb/ft. As a result of the load, the centerline of the beam undergoes a deflection that is described by

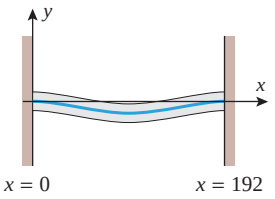
$$y = -1.67 \times 10^{-8}(x^4 - 2Lx^3 + L^2x^2)$$

$(0 \le x \le 192)$, where $L = 192$ in is the length of the unloaded beam, $x$ is the horizontal distance along the beam measured in inches from the left end, and $y$ is the deflection of the centerline in inches.

(a) Graph $y$ versus $x$ for $0 \le x \le 192$.

(b) Find the maximum deflection of the centerline.

(c) Use a CAS or a calculator with a numerical integration capability to find the length of the centerline of the loaded beam. Round your answer to two decimal places.



◀ **Figure Ex-24**

C **25.** A golfer makes a successful chip shot to the green. Suppose that the path of the ball from the moment it is struck to the moment it hits the green is described by

$$y = 12.54x - 0.41x^2$$

where $x$ is the horizontal distance (in yards) from the point where the ball is struck, and $y$ is the vertical distance (in yards) above the fairway. Use a CAS or a calculating utility with a numerical integration capability to find the distance the ball travels from the moment it is struck to the moment it hits the green. Assume that the fairway and green are at the same level and round your answer to two decimal places.

**26–34** These exercises assume familiarity with the basic concepts of parametric curves. If needed, an introduction to this material is provided in Web Appendix I. ■

C **26.** Assume that no segment of the curve

$$x = x(t), \quad y = y(t), \quad (a \le t \le b)$$

is traced more than once as $t$ increases from $a$ to $b$. Divide the interval $[a, b]$ into $n$ subintervals by inserting points $t_1, t_2, \ldots, t_{n-1}$ between $a = t_0$ and $b = t_n$. Let $L$ denote the arc length of the curve. Give an informal argument for the approximation

$$L \approx \sum_{k=1}^{n} \sqrt{[x(t_k) - x(t_{k-1})]^2 + [y(t_k) - y(t_{k-1})]^2}$$

If $dx/dt$ and $dy/dt$ are continuous functions for $a \le t \le b$, then it can be shown that as $\max \Delta t_k \to 0$, this sum converges to

$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt$$

**27–32** Use the arc length formula from Exercise 26 to find the arc length of the curve. ■

**27.** $x = \frac{1}{3}t^3, \ y = \frac{1}{2}t^2 \quad (0 \le t \le 1)$

**28.** $x = (1+t)^2, \ y = (1+t)^3 \quad (0 \le t \le 1)$

**29.** $x = \cos 2t, \ y = \sin 2t \quad (0 \le t \le \pi/2)$

**30.** $x = \cos t + t \sin t, \ y = \sin t - t \cos t \quad (0 \le t \le \pi)$

**31.** $x = e^t \cos t, \ y = e^t \sin t \quad (0 \le t \le \pi/2)$

**32.** $x = e^t(\sin t + \cos t), \ y = e^t(\cos t - \sin t) \quad (1 \le t \le 4)$

C **33.** (a) Show that the total arc length of the ellipse

$$x = 2\cos t, \quad y = \sin t \qquad (0 \le t \le 2\pi)$$

is given by

$$4\int_0^{\pi/2} \sqrt{1 + 3\sin^2 t}\, dt$$

(b) Use a CAS or a scientific calculator with a numerical integration capability to approximate the arc length in part (a). Round your answer to two decimal places.

(c) Suppose that the parametric equations in part (a) describe the path of a particle moving in the $xy$-plane, where $t$ is time in seconds and $x$ and $y$ are in centimeters. Use a CAS or a scientific calculator with a numerical integration capability to approximate the distance traveled by the particle from $t = 1.5$ s to $t = 4.8$ s. Round your answer to two decimal places.

**34.** Show that the total arc length of the ellipse $x = a\cos t$, $y = b\sin t$, $0 \le t \le 2\pi$ for $a > b > 0$ is given by

$$4a\int_0^{\pi/2} \sqrt{1 - k^2\cos^2 t}\, dt$$

where $k = \sqrt{a^2 - b^2}/a$.

**35.** **Writing** In our discussion of Arc Length Problem 6.4.1, we derived the approximation

$$L \approx \sum_{k=1}^{n} \sqrt{1 + [f'(x_k^*)]^2}\, \Delta x_k$$

Discuss the geometric meaning of this approximation. (Be sure to address the appearance of the derivative $f'$.)

**36.** **Writing** Give examples in which Formula (4) for arc length cannot be applied directly, and describe how you would go about finding the arc length of the curve in each case. (Discuss both the use of alternative formulas and the use of numerical methods.)

## ✔ QUICK CHECK ANSWERS 6.4

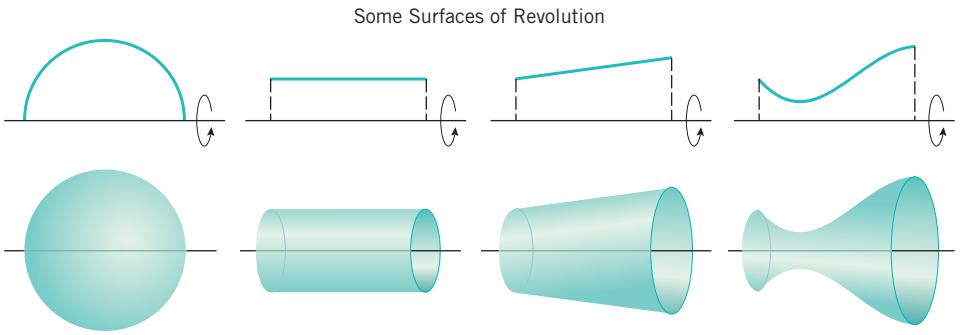
**1.** continuous **2.** $\displaystyle\int_a^b \sqrt{1 + [f'(x)]^2}\, dx$ **3.** $\sqrt{(e-1)^2 + 1}$ **4.** (a) $\displaystyle\int_1^e \sqrt{1 + (1/x)^2}\, dx$ (b) $\displaystyle\int_0^1 \sqrt{1 + e^{2y}}\, dy$

# 6.5 AREA OF A SURFACE OF REVOLUTION

*In this section we will consider the problem of finding the area of a surface that is generated by revolving a plane curve about a line.*

## SURFACE AREA

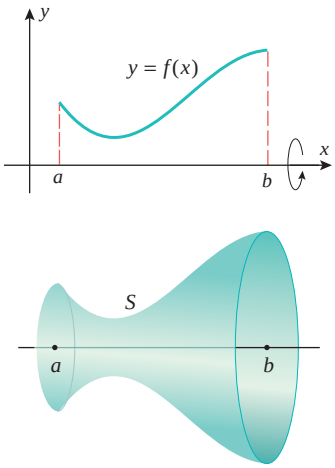
A ***surface of revolution*** is a surface that is generated by revolving a plane curve about an axis that lies in the same plane as the curve. For example, the surface of a sphere can be generated by revolving a semicircle about its diameter, and the lateral surface of a right circular cylinder can be generated by revolving a line segment about an axis that is parallel to it (Figure 6.5.1).



▶ **Figure 6.5.1**

In this section we will be concerned with the following problem.

**6.5.1 SURFACE AREA PROBLEM** Suppose that $f$ is a smooth, nonnegative function on $[a, b]$ and that a surface of revolution is generated by revolving the portion of the curve $y = f(x)$ between $x = a$ and $x = b$ about the $x$-axis (Figure 6.5.2). Define what is meant by the *area* $S$ of the surface, and find a formula for computing it.



▲ **Figure 6.5.2**

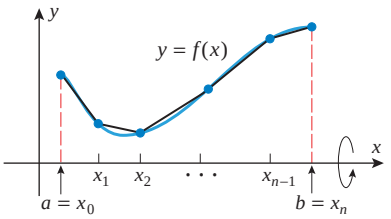
To motivate an appropriate definition for the area $S$ of a surface of revolution, we will decompose the surface into small sections whose areas can be approximated by elementary formulas, add the approximations of the areas of the sections to form a Riemann sum that approximates $S$, and then take the limit of the Riemann sums to obtain an integral for the exact value of $S$.

To implement this idea, divide the interval $[a, b]$ into $n$ subintervals by inserting points $x_1$, $x_2, \ldots, x_{n-1}$ between $a = x_0$ and $b = x_n$. As illustrated in Figure 6.5.3*a*, the corresponding points on the graph of $f$ define a polygonal path that approximates the curve $y = f(x)$ over the interval $[a, b]$. As illustrated in Figure 6.5.3*b*, when this polygonal path is revolved about the $x$-axis, it generates a surface consisting of $n$ parts, each of which is a portion of a right circular cone called a ***frustum*** (from the Latin meaning "bit" or "piece"). Thus, the area of each part of the approximating surface can be obtained from the formula

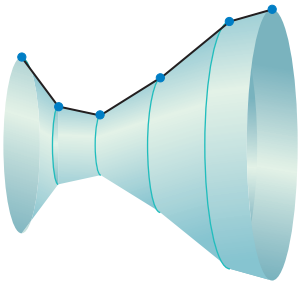
$$S = \pi(r_1 + r_2)l \tag{1}$$

for the lateral area $S$ of a frustum of slant height $l$ and base radii $r_1$ and $r_2$ (Figure 6.5.4). As suggested by Figure 6.5.5, the $k$th frustum has radii $f(x_{k-1})$ and $f(x_k)$ and height $\Delta x_k$. Its slant height is the length $L_k$ of the $k$th line segment in the polygonal path, which from Formula (1) of Section 6.4 is

$$L_k = \sqrt{(\Delta x_k)^2 + [f(x_k) - f(x_{k-1})]^2}$$

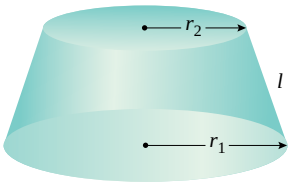


(a)



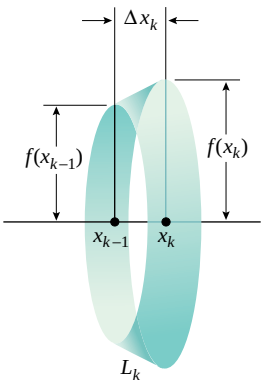
(b)

▲ Figure 6.5.3



Frustum

▲ Figure 6.5.4



▲ Figure 6.5.5

This makes the lateral area $S_k$ of the $k$th frustum

$$S_k = \pi[f(x_{k-1}) + f(x_k)]\sqrt{(\Delta x_k)^2 + [f(x_k) - f(x_{k-1})]^2}$$

If we add these areas, we obtain the following approximation to the area $S$ of the entire surface:

$$S \approx \sum_{k=1}^{n} \pi[f(x_{k-1}) + f(x_k)]\sqrt{(\Delta x_k)^2 + [f(x_k) - f(x_{k-1})]^2} \tag{2}$$

To put this in the form of a Riemann sum we will apply the Mean-Value Theorem (4.8.2). This theorem implies that there is a point $x_k^*$ between $x_{k-1}$ and $x_k$ such that

$$\frac{f(x_k) - f(x_{k-1})}{x_k - x_{k-1}} = f'(x_k^*) \quad \text{or} \quad f(x_k) - f(x_{k-1}) = f'(x_k^*)\Delta x_k$$

and hence we can rewrite (2) as

$$\begin{aligned} S &\approx \sum_{k=1}^{n} \pi[f(x_{k-1}) + f(x_k)]\sqrt{(\Delta x_k)^2 + [f'(x_k^*)]^2(\Delta x_k)^2} \\ &= \sum_{k=1}^{n} \pi[f(x_{k-1}) + f(x_k)]\sqrt{1 + [f'(x_k^*)]^2}\,\Delta x_k \end{aligned} \tag{3}$$

However, this is not yet a Riemann sum because it involves the variables $x_{k-1}$ and $x_k$. To eliminate these variables from the expression, observe that the average value of the numbers $f(x_{k-1})$ and $f(x_k)$ lies between these numbers, so the continuity of $f$ and the Intermediate-Value Theorem (1.5.7) imply that there is a point $x_k^{**}$ between $x_{k-1}$ and $x_k$ such that

$$\tfrac{1}{2}[f(x_{k-1}) + f(x_k)] = f(x_k^{**})$$

Thus, (2) can be expressed as

$$S \approx \sum_{k=1}^{n} 2\pi f(x_k^{**})\sqrt{1 + [f'(x_k^*)]^2}\,\Delta x_k$$

Although this expression is close to a Riemann sum in form, it is not a true Riemann sum because it involves two variables $x_k^*$ and $x_k^{**}$, rather than $x_k^*$ alone. However, it is proved in advanced calculus courses that this has no effect on the limit because of the continuity of $f$. Thus, we can assume that $x_k^{**} = x_k^*$ when taking the limit, and this suggests that $S$ can be defined as

$$S = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} 2\pi f(x_k^{**})\sqrt{1 + [f'(x_k^*)]^2}\,\Delta x_k = \int_a^b 2\pi f(x)\sqrt{1 + [f'(x)]^2}\,dx$$

In summary, we have the following definition.

**6.5.2 DEFINITION** If $f$ is a smooth, nonnegative function on $[a, b]$, then the surface area $S$ of the surface of revolution that is generated by revolving the portion of the curve $y = f(x)$ between $x = a$ and $x = b$ about the $x$-axis is defined as

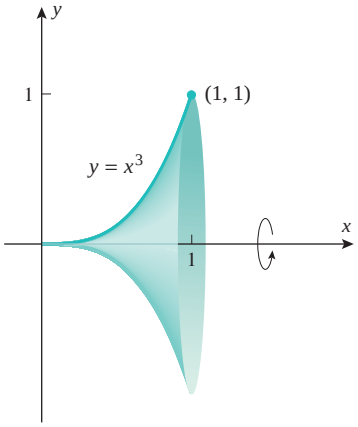
$$S = \int_a^b 2\pi f(x)\sqrt{1 + [f'(x)]^2}\,dx$$

This result provides both a definition and a formula for computing surface areas. Where convenient, this formula can also be expressed as

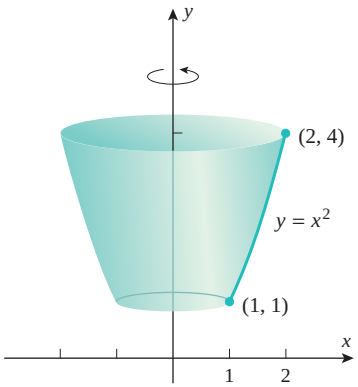
$$S = \int_a^b 2\pi f(x)\sqrt{1 + [f'(x)]^2}\,dx = \int_a^b 2\pi y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx \tag{4}$$

Moreover, if $g$ is nonnegative and $x = g(y)$ is a smooth curve on the interval $[c, d]$, then the area of the surface that is generated by revolving the portion of a curve $x = g(y)$ between $y = c$ and $y = d$ about the $y$-axis can be expressed as

$$S = \int_c^d 2\pi g(y)\sqrt{1 + [g'(y)]^2}\,dy = \int_c^d 2\pi x\sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy \tag{5}$$



▲ **Figure 6.5.6**



▲ **Figure 6.5.7**

▶ **Example 1** Find the area of the surface that is generated by revolving the portion of the curve $y = x^3$ between $x = 0$ and $x = 1$ about the $x$-axis.

***Solution.*** First sketch the curve; then imagine revolving it about the $x$-axis (Figure 6.5.6). Since $y = x^3$, we have $dy/dx = 3x^2$, and hence from (4) the surface area $S$ is

$$\begin{aligned} S &= \int_0^1 2\pi y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx \\ &= \int_0^1 2\pi x^3\sqrt{1 + (3x^2)^2}\,dx \\ &= 2\pi\int_0^1 x^3(1 + 9x^4)^{1/2}\,dx \\ &= \frac{2\pi}{36}\int_1^{10} u^{1/2}\,du \qquad \begin{matrix} u = 1 + 9x^4 \\ du = 36x^3\,dx \end{matrix} \\ &= \frac{2\pi}{36}\cdot\frac{2}{3}u^{3/2}\Big]_{u=1}^{10} = \frac{\pi}{27}(10^{3/2} - 1) \approx 3.56 \end{aligned}$$

◀

▶ **Example 2** Find the area of the surface that is generated by revolving the portion of the curve $y = x^2$ between $x = 1$ and $x = 2$ about the $y$-axis.

***Solution.*** First sketch the curve; then imagine revolving it about the $y$-axis (Figure 6.5.7). Because the curve is revolved about the $y$-axis we will apply Formula (5). Toward this end, we rewrite $y = x^2$ as $x = \sqrt{y}$ and observe that the $y$-values corresponding to $x = 1$ and

$x = 2$ are $y = 1$ and $y = 4$. Since $x = \sqrt{y}$, we have $dx/dy = 1/(2\sqrt{y})$, and hence from (5) the surface area $S$ is

$$S = \int_1^4 2\pi x \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\, dy$$

$$= \int_1^4 2\pi\sqrt{y}\sqrt{1 + \left(\frac{1}{2\sqrt{y}}\right)^2}\, dy$$

$$= \pi \int_1^4 \sqrt{4y + 1}\, dy$$

$$= \frac{\pi}{4}\int_5^{17} u^{1/2}\, du \qquad \begin{matrix} u = 4y + 1 \\ du = 4\, dy \end{matrix}$$

$$= \frac{\pi}{4} \cdot \frac{2}{3} u^{3/2}\Big]_{u=5}^{17} = \frac{\pi}{6}(17^{3/2} - 5^{3/2}) \approx 30.85 \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 6.5 (See page 449 for answers.)

1. If $f$ is a smooth, nonnegative function on $[a, b]$, then the surface area $S$ of the surface of revolution generated by revolving the portion of the curve $y = f(x)$ between $x = a$ and $x = b$ about the $x$-axis is _____.
2. The lateral area of the frustum with slant height $\sqrt{10}$ and base radii $r_1 = 1$ and $r_2 = 2$ is _____.
3. An integral expression for the area of the surface generated by rotating the line segment joining (3, 1) and (6, 2) about the $x$-axis is _____.
4. An integral expression for the area of the surface generated by rotating the line segment joining (3, 1) and (6, 2) about the $y$-axis is _____.

## EXERCISE SET 6.5 C CAS

**1–4** Find the area of the surface generated by revolving the given curve about the $x$-axis. ■

1. $y = 7x,\ 0 \le x \le 1$
2. $y = \sqrt{x},\ 1 \le x \le 4$
3. $y = \sqrt{4 - x^2},\ -1 \le x \le 1$
4. $x = \sqrt[3]{y},\ 1 \le y \le 8$

**5–8** Find the area of the surface generated by revolving the given curve about the $y$-axis. ■

5. $x = 9y + 1,\ 0 \le y \le 2$
6. $x = y^3,\ 0 \le y \le 1$
7. $x = \sqrt{9 - y^2},\ -2 \le y \le 2$
8. $x = 2\sqrt{1 - y},\ -1 \le y \le 0$

C **9–12** Use a CAS to find the exact area of the surface generated by revolving the curve about the stated axis. ■

9. $y = \sqrt{x} - \frac{1}{3}x^{3/2},\ 1 \le x \le 3;\ x$-axis
10. $y = \frac{1}{3}x^3 + \frac{1}{4}x^{-1},\ 1 \le x \le 2;\ x$-axis
11. $8xy^2 = 2y^6 + 1,\ 1 \le y \le 2;\ y$-axis
12. $x = \sqrt{16 - y},\ 0 \le y \le 15;\ y$-axis

C **13–16** Use a CAS or a calculating utility with a numerical integration capability to approximate the area of the surface generated by revolving the curve about the stated axis. Round your answer to two decimal places. ■

13. $y = \sin x,\ 0 \le x \le \pi;\ x$-axis
14. $x = \tan y,\ 0 \le y \le \pi/4;\ y$-axis
15. $y = e^x,\ 0 \le x \le 1;\ x$-axis
16. $y = e^x,\ 1 \le y \le e;\ y$-axis

**17–20 True–False** Determine whether the statement is true or false. Explain your answer. ■

17. The lateral surface area $S$ of a right circular cone with height $h$ and base radius $r$ is $S = \pi r\sqrt{r^2 + h^2}$.
18. The lateral surface area of a frustum of slant height $l$ and base radii $r_1$ and $r_2$ is equal to the lateral surface area of a right circular cylinder of height $l$ and radius equal to the average of $r_1$ and $r_2$.

**19.** The approximation

$$S \approx \sum_{k=1}^{n} 2\pi f(x_k^{**})\sqrt{1+[f'(x_k^{*})]^2}\,\Delta x_k$$

for surface area is exact if $f$ is a positive-valued constant function.

**20.** The expression

$$\sum_{k=1}^{n} 2\pi f(x_k^{**})\sqrt{1+[f'(x_k^{*})]^2}\,\Delta x_k$$

is not a true Riemann sum for

$$\int_a^b 2\pi f(x)\sqrt{1+[f'(x)]^2}\,dx$$

**21–22** Approximate the area of the surface using Formula (2) with $n = 20$ subintervals of equal width. Round your answer to two decimal places. ■

**21.** The surface of Exercise 13.

**22.** The surface of Exercise 16.

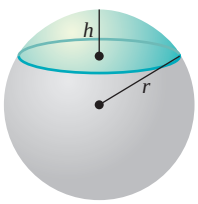
**FOCUS ON CONCEPTS**

**23.** Assume that $y = f(x)$ is a smooth curve on the interval $[a, b]$ and assume that $f(x) \geq 0$ for $a \leq x \leq b$. Derive a formula for the surface area generated when the curve $y = f(x)$, $a \leq x \leq b$, is revolved about the line $y = -k$ $(k > 0)$.

**24.** Would it be circular reasoning to use Definition 6.5.2 to find the surface area of a frustum of a right circular cone? Explain your answer.

**25.** Show that the area of the surface of a sphere of radius $r$ is $4\pi r^2$. [*Hint:* Revolve the semicircle $y = \sqrt{r^2 - x^2}$ about the $x$-axis.]

**26.** The accompanying figure shows a spherical cap of height $h$ cut from a sphere of radius $r$. Show that the surface area $S$ of the cap is $S = 2\pi rh$. [*Hint:* Revolve an appropriate portion of the circle $x^2 + y^2 = r^2$ about the $y$-axis.]



◀ **Figure Ex-26**

**27.** The portion of a sphere that is cut by two parallel planes is called a ***zone***. Use the result of Exercise 26 to show that the surface area of a zone depends on the radius of the sphere and the distance between the planes, but not on the location of the zone.

**28.** Let $y = f(x)$ be a smooth curve on the interval $[a, b]$ and assume that $f(x) \geq 0$ for $a \leq x \leq b$. By the Extreme-Value Theorem (4.4.2), the function $f$ has a maximum value $K$ and a minimum value $k$ on $[a, b]$. Prove: If $L$ is the arc length of the curve $y = f(x)$ between $x = a$ and $x = b$, and if $S$ is the area of the surface that is generated by revolving this curve about the $x$-axis, then

$$2\pi kL \leq S \leq 2\pi KL$$

**29.** Use the results of Exercise 28 above and Exercise 21 in Section 6.4 to show that the area $S$ of the surface generated by revolving the curve $y = \sec x$, $0 \leq x \leq \pi/3$, about the $x$-axis satisfies

$$\frac{2\pi^2}{3} \leq S \leq \frac{4\pi^2}{3}\sqrt{13}$$

**30.** Let $y = f(x)$ be a smooth curve on $[a, b]$ and assume that $f(x) \geq 0$ for $a \leq x \leq b$. Let $A$ be the area under the curve $y = f(x)$ between $x = a$ and $x = b$, and let $S$ be the area of the surface obtained when this section of curve is revolved about the $x$-axis.

(a) Prove that $2\pi A \leq S$.

(b) For what functions $f$ is $2\pi A = S$?

**31–37** These exercises assume familiarity with the basic concepts of parametric curves. If needed, an introduction to this material is provided in Web Appendix I. ■

**31–32** For these exercises, divide the interval $[a, b]$ into $n$ subintervals by inserting points $t_1, t_2, \ldots, t_{n-1}$ between $a = t_0$ and $b = t_n$, and assume that $x'(t)$ and $y'(t)$ are continuous functions and that no segment of the curve

$$x = x(t), \quad y = y(t) \qquad (a \leq t \leq b)$$

is traced more than once. ■

**31.** Let $S$ be the area of the surface generated by revolving the curve $x = x(t)$, $y = y(t)$ $(a \leq t \leq b)$ about the $x$-axis. Explain how $S$ can be approximated by

$$S \approx \sum_{k=1}^{n} (\pi[y(t_{k-1}) + y(t_k)] \times \sqrt{[x(t_k) - x(t_{k-1})]^2 + [y(t_k) - y(t_{k-1})]^2}\,)$$

Using results from advanced calculus, it can be shown that as $\max \Delta t_k \to 0$, this sum converges to

$$S = \int_a^b 2\pi y(t)\sqrt{[x'(t)]^2 + [y'(t)]^2}\,dt \qquad \text{(A)}$$

**32.** Let $S$ be the area of the surface generated by revolving the curve $x = x(t)$, $y = y(t)$ $(a \leq t \leq b)$ about the $y$-axis. Explain how $S$ can be approximated by

$$S \approx \sum_{k=1}^{n} (\pi[x(t_{k-1}) + x(t_k)] \times \sqrt{[x(t_k) - x(t_{k-1})]^2 + [y(t_k) - y(t_{k-1})]^2}\,)$$

Using results from advanced calculus, it can be shown that as $\max \Delta t_k \to 0$, this sum converges to

$$S = \int_a^b 2\pi x(t)\sqrt{[x'(t)]^2 + [y'(t)]^2}\,dt \qquad \text{(B)}$$

**33–37** Use Formulas (A) and (B) from Exercises 31 and 32. ■

**33.** Find the area of the surface generated by revolving the parametric curve $x = t^2$, $y = 2t$ $(0 \le t \le 4)$ about the $x$-axis.

C **34.** Use a CAS to find the area of the surface generated by revolving the parametric curve

$$x = \cos^2 t, \quad y = 5 \sin t \qquad (0 \le t \le \pi/2)$$

about the $x$-axis.

**35.** Find the area of the surface generated by revolving the parametric curve $x = t$, $y = 2t^2$ $(0 \le t \le 1)$ about the $y$-axis.

**36.** Find the area of the surface generated by revolving the parametric curve $x = \cos^2 t$, $y = \sin^2 t$ $(0 \le t \le \pi/2)$ about the $y$-axis.

**37.** By revolving the semicircle

$$x = r \cos t, \quad y = r \sin t \qquad (0 \le t \le \pi)$$

about the $x$-axis, show that the surface area of a sphere of radius $r$ is $4\pi r^2$.

**38.** **Writing** Compare the derivation of Definition 6.5.2 with that of Definition 6.4.2. Discuss the geometric features that result in similarities in the two definitions.

**39.** **Writing** Discuss what goes wrong if we replace the frustums of right circular cones by right circular cylinders in the derivation of Definition 6.5.2.

## ✔ QUICK CHECK ANSWERS 6.5

**1.** $\displaystyle\int_a^b 2\pi f(x)\sqrt{1 + [f'(x)]^2}\,dx$ **2.** $3\sqrt{10}\,\pi$ **3.** $\displaystyle\int_3^6 (2\pi)\left(\frac{x}{3}\right)\sqrt{\frac{10}{9}}\,dx = \int_3^6 \frac{2\sqrt{10}\,\pi}{9}x\,dx$ **4.** $\displaystyle\int_1^2 (2\pi)(3y)\sqrt{10}\,dy$

# 6.6 WORK

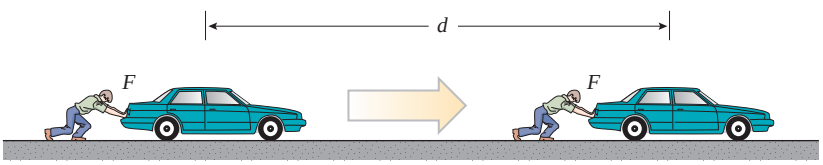
*In this section we will use the integration tools developed in the preceding chapter to study some of the basic principles of "work," which is one of the fundamental concepts in physics and engineering.*

## THE ROLE OF WORK IN PHYSICS AND ENGINEERING

In this section we will be concerned with two related concepts, *work* and *energy*. To put these ideas in a familiar setting, when you push a stalled car for a certain distance you are performing work, and the effect of your work is to make the car move. The energy of motion caused by the work is called the *kinetic energy* of the car. The exact connection between work and kinetic energy is governed by a principle of physics called the *work–energy relationship*. Although we will touch on this idea in this section, a detailed study of the relationship between work and energy will be left for courses in physics and engineering. Our primary goal here will be to explain the role of integration in the study of work.

## WORK DONE BY A CONSTANT FORCE APPLIED IN THE DIRECTION OF MOTION

When a stalled car is pushed, the speed that the car attains depends on the force $F$ with which it is pushed and the distance $d$ over which that force is applied (Figure 6.6.1). Force and distance appear in the following definition of work.



▶ **Figure 6.6.1**

**6.6.1 DEFINITION** If a constant force of magnitude $F$ is applied in the direction of motion of an object, and if that object moves a distance $d$, then we define the ***work*** $W$ performed by the force on the object to be

$$W = F \cdot d \tag{1}$$

If you push against an immovable object, such as a brick wall, you may tire yourself out, but you will not perform any work. Why?

Common units for measuring force are newtons (N) in the International System of Units (SI), dynes (dyn) in the centimeter-gram-second (CGS) system, and pounds (lb) in the British Engineering (BE) system. One newton is the force required to give a mass of 1 kg an acceleration of 1 m/s$^2$, one dyne is the force required to give a mass of 1 g an acceleration of 1 cm/s$^2$, and one pound of force is the force required to give a mass of 1 slug an acceleration of 1 ft/s$^2$.

It follows from Definition 6.6.1 that work has units of force times distance. The most common units of work are newton-meters (N·m), dyne-centimeters (dyn·cm), and foot-pounds (ft·lb). As indicated in Table 6.6.1, one newton-meter is also called a ***joule*** (J), and one dyne-centimeter is also called an ***erg***. One foot-pound is approximately 1.36 J.

**Table 6.6.1**

| SYSTEM | FORCE | × | DISTANCE | = | WORK |
|---|---|---|---|---|---|
| SI | newton (N) | | meter (m) | | joule (J) |
| CGS | dyne (dyn) | | centimeter (cm) | | erg |
| BE | pound (lb) | | foot (ft) | | foot-pound (ft·lb) |

CONVERSION FACTORS:

$1\text{ N} = 10^5\text{ dyn} \approx 0.225\text{ lb}$ $\qquad$ $1\text{ lb} \approx 4.45\text{ N}$

$1\text{ J} = 10^7\text{ erg} \approx 0.738\text{ ft·lb}$ $\qquad$ $1\text{ ft·lb} \approx 1.36\text{ J} = 1.36 \times 10^7\text{ erg}$

**▶ Example 1** An object moves 5 ft along a line while subjected to a constant force of 100 lb in its direction of motion. The work done is

$$W = F \cdot d = 100 \cdot 5 = 500\text{ ft·lb}$$

An object moves 25 m along a line while subjected to a constant force of 4 N in its direction of motion. The work done is

$$W = F \cdot d = 4 \cdot 25 = 100\text{ N·m} = 100\text{ J} \quad \blacktriangleleft$$

Stephen Sutton/DUOMO Archive/PCN Photography Inc.

*Vasili Alexeev shown lifting a record-breaking 562 lb in the 1976 Olympics. In eight successive years he won Olympic gold medals, captured six world championships, and broke 80 world records. In 1999 he was honored in Greece as the best sportsman of the twentieth century.*

**▶ Example 2** In the 1976 Olympics, Vasili Alexeev astounded the world by lifting a record-breaking 562 lb from the floor to above his head (about 2 m). Equally astounding was the feat of strongman Paul Anderson, who in 1957 braced himself on the floor and used his back to lift 6270 lb of lead and automobile parts a distance of 1 cm. Who did more work?

***Solution.*** To lift an object one must apply sufficient force to overcome the gravitational force that the Earth exerts on that object. The force that the Earth exerts on an object is that object's weight; thus, in performing their feats, Alexeev applied a force of 562 lb over a distance of 2 m and Anderson applied a force of 6270 lb over a distance of 1 cm. Pounds are units in the BE system, meters are units in SI, and centimeters are units in the CGS system. We will need to decide on the measurement system we want to use and be consistent. Let us agree to use SI and express the work of the two men in joules. Using the conversion factor in Table 6.6.1 we obtain

$$562\text{ lb} \approx 562\text{ lb} \times 4.45\text{ N/lb} \approx 2500\text{ N}$$

$$6270\text{ lb} \approx 6270\text{ lb} \times 4.45\text{ N/lb} \approx 27{,}900\text{ N}$$

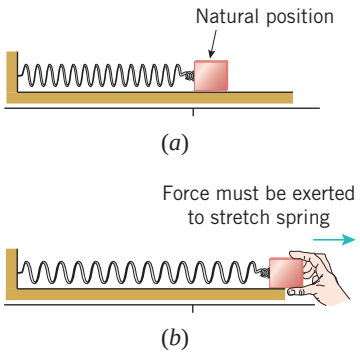
Using these values and the fact that 1 cm = 0.01 m we obtain

$$\text{Alexeev's work} = (2500\text{ N}) \times (2\text{ m}) = 5000\text{ J}$$
$$\text{Anderson's work} = (27{,}900\text{ N}) \times (0.01\text{ m}) = 279\text{ J}$$

Therefore, even though Anderson's lift required a tremendous upward force, it was applied over such a short distance that Alexeev did more work. ◀

## WORK DONE BY A VARIABLE FORCE APPLIED IN THE DIRECTION OF MOTION

Many important problems are concerned with finding the work done by a *variable* force that is applied in the direction of motion. For example, Figure 6.6.2*a* shows a spring in its natural state (neither compressed nor stretched). If we want to pull the block horizontally (Figure 6.6.2*b*), then we would have to apply more and more force to the block to overcome the increasing force of the stretching spring. Thus, our next objective is to define what is meant by the work performed by a variable force and to find a formula for computing it. This will require calculus.



▲ **Figure 6.6.2**

**6.6.2 PROBLEM** Suppose that an object moves in the positive direction along a coordinate line while subjected to a variable force $F(x)$ that is applied in the direction of motion. Define what is meant by the *work* $W$ performed by the force on the object as the object moves from $x = a$ to $x = b$, and find a formula for computing the work.

The basic idea for solving this problem is to break up the interval $[a, b]$ into subintervals that are sufficiently small that the force does not vary much on each subinterval. This will allow us to treat the force as constant on each subinterval and to approximate the work on each subinterval using Formula (1). By adding the approximations to the work on the subintervals, we will obtain a Riemann sum that approximates the work $W$ over the entire interval, and by taking the limit of the Riemann sums we will obtain an integral for $W$.

To implement this idea, divide the interval $[a, b]$ into $n$ subintervals by inserting points $x_1, x_2, \ldots, x_{n-1}$ between $a = x_0$ and $b = x_n$. We can use Formula (1) to approximate the work $W_k$ done in the $k$th subinterval by choosing any point $x_k^*$ in this interval and regarding the force to have a constant value $F(x_k^*)$ throughout the interval. Since the width of the $k$th subinterval is $x_k - x_{k-1} = \Delta x_k$, this yields the approximation

$$W_k \approx F(x_k^*)\Delta x_k$$

Adding these approximations yields the following Riemann sum that approximates the work $W$ done over the entire interval:

$$W \approx \sum_{k=1}^{n} F(x_k^*)\Delta x_k$$

Taking the limit as $n$ increases and the widths of all the subintervals approach zero yields the definite integral

$$W = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} F(x_k^*)\Delta x_k = \int_a^b F(x)\,dx$$

In summary, we have the following result.

**6.6.3 DEFINITION** Suppose that an object moves in the positive direction along a coordinate line over the interval $[a, b]$ while subjected to a variable force $F(x)$ that is applied in the direction of motion. Then we define the ***work*** $W$ performed by the force on the object to be

$$W = \int_a^b F(x)\,dx \tag{2}$$

***Hooke's law*** [Robert Hooke (1635–1703), English physicist] states that under appropriate conditions a spring that is stretched $x$ units beyond its natural length pulls back with a force

$$F(x) = kx$$

where $k$ is a constant (called the ***spring constant*** or ***spring stiffness***). The value of $k$ depends on such factors as the thickness of the spring and the material used in its composition. Since $k = F(x)/x$, the constant $k$ has units of force per unit length.

**▶ Example 3** A spring exerts a force of 5 N when stretched 1 m beyond its natural length.

(a) Find the spring constant $k$.

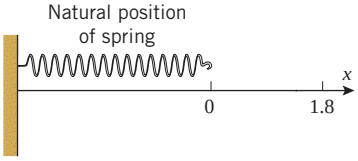
(b) How much work is required to stretch the spring 1.8 m beyond its natural length?

***Solution (a).*** From Hooke's law,

$$F(x) = kx$$

From the data, $F(x) = 5$ N when $x = 1$ m, so $5 = k \cdot 1$. Thus, the spring constant is $k = 5$ newtons per meter (N/m). This means that the force $F(x)$ required to stretch the spring $x$ meters is

$$F(x) = 5x \tag{3}$$



▲ **Figure 6.6.3**

***Solution (b).*** Place the spring along a coordinate line as shown in Figure 6.6.3. We want to find the work $W$ required to stretch the spring over the interval from $x = 0$ to $x = 1.8$. From (2) and (3) the work $W$ required is

$$W = \int_a^b F(x)\,dx = \int_0^{1.8} 5x\,dx = \frac{5x^2}{2}\Big]_0^{1.8} = 8.1 \text{ J} \quad \blacktriangleleft$$

NASA Marshall Space Flight Center Collection
*The International Space Station has had continuous human occupation since November 2, 2000 and is a cooperative effort of the United States, Russia, Europe, Japan, and Canada.*

**▶ Example 4** An astronaut's *weight* (or more precisely, *Earth weight*) is the force exerted on the astronaut by the Earth's gravity. As the astronaut moves upward into space, the gravitational pull of the Earth decreases, and hence so does his or her weight. If the Earth is assumed to be a sphere of radius 4000 mi, then it follows from Newton's Law of Universal Gravitation that an astronaut who weighs 150 lb on Earth will have a weight of

$$w(x) = \frac{2{,}400{,}000{,}000}{x^2} \text{ lb}, \quad x \geq 4000$$

at a distance of $x$ miles from the Earth's center (Exercise 25). Use this formula to estimate the work in foot-pounds required to lift the astronaut 220 miles upward to the International Space Station.

***Solution.*** Since the Earth has a radius of 4000 mi, the astronaut is lifted from a point that is 4000 mi from the Earth's center to a point that is 4220 mi from the Earth's center. Thus,

from (2), the work $W$ required to lift the astronaut is

$$\begin{aligned} W &= \int_{4000}^{4220} \frac{2{,}400{,}000{,}000}{x^2}\,dx \\ &= -\frac{2{,}400{,}000{,}000}{x}\Bigg]_{4000}^{4220} \\ &\approx -568{,}720 + 600{,}000 \\ &= 31{,}280 \text{ mile-pounds} \\ &= (31{,}280 \text{ mi·lb}) \times (5280 \text{ ft/mi}) \\ &\approx 1.65 \times 10^8 \text{ ft·lb} \quad \blacktriangleleft \end{aligned}$$

## CALCULATING WORK FROM BASIC PRINCIPLES

Some problems cannot be solved by mechanically substituting into formulas, and one must return to basic principles to obtain solutions. This is illustrated in the next example.

**▶ Example 5** Figure 6.6.4*a* shows a conical container of radius 10 ft and height 30 ft. Suppose that this container is filled with water to a depth of 15 ft. How much work is required to pump all of the water out through a hole in the top of the container?

***Solution.*** Our strategy will be to divide the water into thin layers, approximate the work required to move each layer to the top of the container, add the approximations for the layers to obtain a Riemann sum that approximates the total work, and then take the limit of the Riemann sums to produce an integral for the total work.

To implement this idea, introduce an $x$-axis as shown in Figure 6.6.4*a*, and divide the water into $n$ layers with $\Delta x_k$ denoting the thickness of the $k$th layer. This division induces a partition of the interval $[15, 30]$ into $n$ subintervals. Although the upper and lower surfaces of the $k$th layer are at different distances from the top, the difference will be small if the layer is thin, and we can reasonably assume that the entire layer is concentrated at a single point $x_k^*$ (Figure 6.6.4*a*). Thus, the work $W_k$ required to move the $k$th layer to the top of the container is approximately

$$W_k \approx F_k x_k^* \tag{4}$$

where $F_k$ is the force required to lift the $k$th layer. But the force required to lift the $k$th layer is the force needed to overcome gravity, and this is the same as the weight of the layer. If the layer is very thin, we can approximate the volume of the $k$th layer with the volume of a cylinder of height $\Delta x_k$ and radius $r_k$, where (by similar triangles)

$$\frac{r_k}{x_k^*} = \frac{10}{30} = \frac{1}{3}$$

or, equivalently, $r_k = x_k^*/3$ (Figure 6.6.4*b*). Therefore, the volume of the $k$th layer of water is approximately

$$\pi r_k^2 \Delta x_k = \pi (x_k^*/3)^2 \Delta x_k = \frac{\pi}{9}(x_k^*)^2 \Delta x_k$$

Since the weight density of water is 62.4 lb/ft$^3$, it follows that

$$F_k \approx \frac{62.4\pi}{9}(x_k^*)^2 \Delta x_k$$

Thus, from (4)

$$W_k \approx \left(\frac{62.4\pi}{9}(x_k^*)^2 \Delta x_k\right) x_k^* = \frac{62.4\pi}{9}(x_k^*)^3 \Delta x_k$$

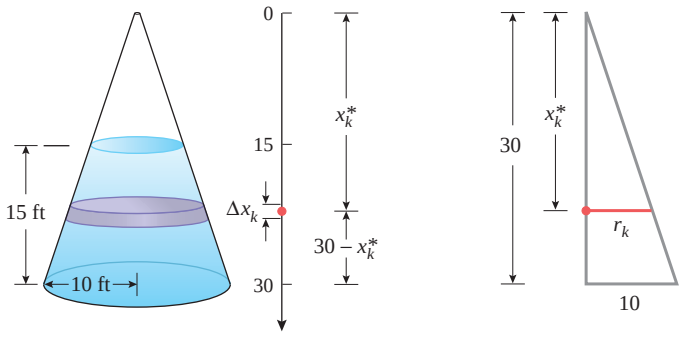
and hence the work $W$ required to move all $n$ layers has the approximation

$$W = \sum_{k=1}^{n} W_k \approx \sum_{k=1}^{n} \frac{62.4\pi}{9}(x_k^*)^3 \Delta x_k$$

To find the *exact* value of the work we take the limit as $\max \Delta x_k \to 0$. This yields

$$W = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} \frac{62.4\pi}{9}(x_k^*)^3 \Delta x_k = \int_{15}^{30} \frac{62.4\pi}{9} x^3 \, dx$$

$$= \frac{62.4\pi}{9}\left(\frac{x^4}{4}\right)\Big]_{15}^{30} = 1{,}316{,}250\pi \approx 4{,}135{,}000 \text{ ft·lb} \quad \blacktriangleleft$$



▶ **Figure 6.6.4**

## THE WORK–ENERGY RELATIONSHIP

Mike Brinson/Getty Images

*The work performed by the skater's stick in a brief interval of time produces the blinding speed of the hockey puck.*

When you see an object in motion, you can be certain that somehow work has been expended to create that motion. For example, when you drop a stone from a building, the stone gathers speed because the force of the Earth's gravity is performing work on it, and when a hockey player strikes a puck with a hockey stick, the work performed on the puck during the brief period of contact with the stick creates the enormous speed of the puck across the ice. However, experience shows that the speed obtained by an object depends not only on the amount of work done, but also on the mass of the object. For example, the work required to throw a 5 oz baseball 50 mi/h would accelerate a 10 lb bowling ball to less than 9 mi/h.

Using the method of substitution for definite integrals, we will derive a simple equation that relates the work done on an object to the object's mass and velocity. Furthermore, this equation will allow us to motivate an appropriate definition for the "energy of motion" of an object. As in Definition 6.6.3, we will assume that an object moves in the positive direction along a coordinate line over the interval $[a, b]$ while subjected to a force $F(x)$ that is applied in the direction of motion. We let $m$ denote the mass of the object, and we let $x = x(t)$, $v = v(t) = x'(t)$, and $a = a(t) = v'(t)$ denote the respective position, velocity, and acceleration of the object at time $t$. We will need the following important result from physics that relates the force acting on an object with the mass and acceleration of the object.

**6.6.4 NEWTON'S SECOND LAW OF MOTION** If an object with mass $m$ is subjected to a force $F$, then the object undergoes an acceleration $a$ that satisfies the equation

$$F = ma \tag{5}$$

It follows from Newton's Second Law of Motion that

$$F(x(t)) = ma(t) = mv'(t)$$

Assume that

$$x(t_0) = a \quad \text{and} \quad x(t_1) = b$$

with

$$v(t_0) = v_i \quad \text{and} \quad v(t_1) = v_f$$

the initial and final velocities of the object, respectively. Then

$$\begin{aligned} W &= \int_a^b F(x)\,dx = \int_{x(t_0)}^{x(t_1)} F(x)\,dx \\ &= \int_{t_0}^{t_1} F(x(t))x'(t)\,dt \qquad \text{By Theorem 5.9.1 with } x = x(t),\ dx = x'(t)\,dt \\ &= \int_{t_0}^{t_1} mv'(t)v(t)\,dt = \int_{t_0}^{t_1} mv(t)v'(t)\,dt \\ &= \int_{v(t_0)}^{v(t_1)} mv\,dv \qquad \text{By Theorem 5.9.1 with } v = v(t),\ dv = v'(t)\,dt \\ &= \int_{v_i}^{v_f} mv\,dv = \tfrac{1}{2}mv^2\Big|_{v_i}^{v_f} = \tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2 \end{aligned}$$

We see from the equation

$$W = \tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2 \tag{6}$$

that the work done on the object is equal to the change in the quantity $\frac{1}{2}mv^2$ from its initial value to its final value. We will refer to Equation (6) as the ***work–energy relationship***. If we define the "energy of motion" or ***kinetic energy*** of our object to be given by

$$K = \tfrac{1}{2}mv^2 \tag{7}$$

then Equation (6) tells us that the work done on an object is equal to the *change* in the object's kinetic energy. Loosely speaking, we may think of work done on an object as being "transformed" into kinetic energy of the object. The units of kinetic energy are the same as the units of work. For example, in SI kinetic energy is measured in joules (J).

▶ **Example 6** A space probe of mass $m = 5.00 \times 10^4$ kg travels in deep space subjected only to the force of its own engine. Starting at a time when the speed of the probe is $v = 1.10 \times 10^4$ m/s, the engine is fired continuously over a distance of $2.50 \times 10^6$ m with a constant force of $4.00 \times 10^5$ N in the direction of motion. What is the final speed of the probe?

***Solution.*** Since the force applied by the engine is constant and in the direction of motion, the work $W$ expended by the engine on the probe is

$$W = \text{force} \times \text{distance} = (4.00 \times 10^5 \text{ N}) \times (2.50 \times 10^6 \text{ m}) = 1.00 \times 10^{12} \text{ J}$$

From (6), the final kinetic energy $K_f = \frac{1}{2}mv_f^2$ of the probe can be expressed in terms of the work $W$ and the initial kinetic energy $K_i = \frac{1}{2}mv_i^2$ as

$$K_f = W + K_i$$

Thus, from the known mass and initial speed we have

$$K_f = (1.00 \times 10^{12} \text{ J}) + \tfrac{1}{2}(5.00 \times 10^4 \text{ kg})(1.10 \times 10^4 \text{ m/s})^2 = 4.025 \times 10^{12} \text{ J}$$

The final kinetic energy is $K_f = \frac{1}{2}mv_f^2$, so the final speed of the probe is

$$v_f = \sqrt{\frac{2K_f}{m}} = \sqrt{\frac{2(4.025 \times 10^{12})}{5.00 \times 10^4}} \approx 1.27 \times 10^4 \text{ m/s} \quad \blacktriangleleft$$

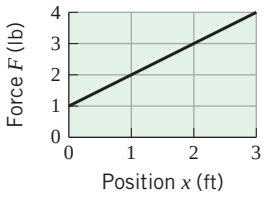
## ✔ QUICK CHECK EXERCISES 6.6 (See page 458 for answers.)

1. If a constant force of 5 lb moves an object 10 ft, then the work done by the force on the object is _____.
2. A newton-meter is also called a _____. A dyne-centimeter is also called an _____.
3. Suppose that an object moves in the positive direction along a coordinate line over the interval $[a, b]$. The work performed on the object by a variable force $F(x)$ applied in the direction of motion is $W =$ _____.
4. A force $F(x) = 10 - 2x$ N applied in the positive $x$-direction moves an object 3 m from $x = 2$ to $x = 5$. The work done by the force on the object is _____.

## EXERCISE SET 6.6

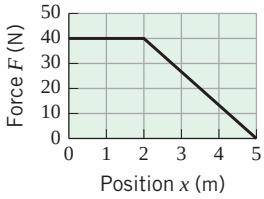
### FOCUS ON CONCEPTS

1. A variable force $F(x)$ in the positive $x$-direction is graphed in the accompanying figure. Find the work done by the force on a particle that moves from $x = 0$ to $x = 3$.



◀ **Figure Ex-1**

2. A variable force $F(x)$ in the positive $x$-direction is graphed in the accompanying figure. Find the work done by the force on a particle that moves from $x = 0$ to $x = 5$.



◀ **Figure Ex-2**

3. For the variable force $F(x)$ in Exercise 2, consider the distance $d$ for which the work done by the force on the particle when the particle moves from $x = 0$ to $x = d$ is half of the work done when the particle moves from $x = 0$ to $x = 5$. By inspecting the graph of $F$, is $d$ more or less than 2.5? Explain, and then find the exact value of $d$.
4. Suppose that a variable force $F(x)$ is applied in the positive $x$-direction so that an object moves from $x = a$ to $x = b$. Relate the work done by the force on the object and the average value of $F$ over $[a, b]$, and illustrate this relationship graphically.
5. A constant force of 10 lb in the positive $x$-direction is applied to a particle whose velocity versus time curve is shown in the accompanying figure. Find the work done by the force on the particle from time $t = 0$ to $t = 5$.

6. A spring exerts a force of 6 N when it is stretched from its natural length of 4 m to a length of $4\frac{1}{2}$ m. Find the work required to stretch the spring from its natural length to a length of 6 m.
7. A spring exerts a force of 100 N when it is stretched 0.2 m beyond its natural length. How much work is required to stretch the spring 0.8 m beyond its natural length?
8. A spring whose natural length is 15 cm exerts a force of 45 N when stretched to a length of 20 cm.
   (a) Find the spring constant (in newtons/meter).
   (b) Find the work that is done in stretching the spring 3 cm beyond its natural length.
   (c) Find the work done in stretching the spring from a length of 20 cm to a length of 25 cm.
9. Assume that 10 ft·lb of work is required to stretch a spring 1 ft beyond its natural length. What is the spring constant?

**10–13 True–False** Determine whether the statement is true or false. Explain your answer. ■

10. In order to support the weight of a parked automobile, the surface of a driveway must do work against the force of gravity on the vehicle.
11. A force of 10 lb in the direction of motion of an object that moves 5 ft in 2 s does six times the work of a force of 10 lb in the direction of motion of an object that moves 5 ft in 12 s.
12. It follows from Hooke's law that in order to double the distance a spring is stretched beyond its natural length, four times as much work is required.
13. In the International System of Units, work and kinetic energy have the same units.

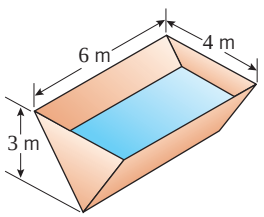
**14.** A cylindrical tank of radius 5 ft and height 9 ft is two-thirds filled with water. Find the work required to pump all the water over the upper rim.

**15.** Solve Exercise 14 assuming that the tank is half-filled with water.

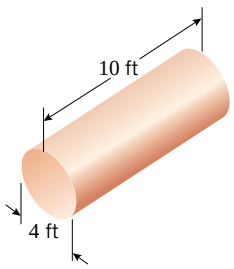
**16.** A cone-shaped water reservoir is 20 ft in diameter across the top and 15 ft deep. If the reservoir is filled to a depth of 10 ft, how much work is required to pump all the water to the top of the reservoir?

**17.** The vat shown in the accompanying figure contains water to a depth of 2 m. Find the work required to pump all the water to the top of the vat. [Use 9810 $\text{N/m}^3$ as the weight density of water.]

**18.** The cylindrical tank shown in the accompanying figure is filled with a liquid weighing 50 $\text{lb/ft}^3$. Find the work required to pump all the liquid to a level 1 ft above the top of the tank.



▲ **Figure Ex-17**



▲ **Figure Ex-18**

**19.** A swimming pool is built in the shape of a rectangular parallelepiped 10 ft deep, 15 ft wide, and 20 ft long.
(a) If the pool is filled to 1 ft below the top, how much work is required to pump all the water into a drain at the top edge of the pool?
(b) A one-horsepower motor can do 550 ft·lb of work per second. What size motor is required to empty the pool in 1 hour?

**20.** How much work is required to fill the swimming pool in Exercise 19 to 1 ft below the top if the water is pumped in through an opening located at the bottom of the pool?

**21.** A 100 ft length of steel chain weighing 15 lb/ft is dangling from a pulley. How much work is required to wind the chain onto the pulley?

**22.** A 3 lb bucket containing 20 lb of water is hanging at the end of a 20 ft rope that weighs 4 oz/ft. The other end of the rope is attached to a pulley. How much work is required to wind the length of rope onto the pulley, assuming that the rope is wound onto the pulley at a rate of 2 ft/s and that as the bucket is being lifted, water leaks from the bucket at a rate of 0.5 lb/s?

**23.** A rocket weighing 3 tons is filled with 40 tons of liquid fuel. In the initial part of the flight, fuel is burned off at a constant rate of 2 tons per 1000 ft of vertical height. How much work in foot-tons (ft·ton) is done lifting the rocket 3000 ft?

**24.** It follows from Coulomb's law in physics that two like electrostatic charges repel each other with a force inversely proportional to the square of the distance between them. Suppose that two charges $A$ and $B$ repel with a force of $k$ newtons when they are positioned at points $A(-a, 0)$ and $B(a, 0)$, where $a$ is measured in meters. Find the work $W$ required to move charge $A$ along the $x$-axis to the origin if charge $B$ remains stationary.

**25.** It follows from Newton's Law of Universal Gravitation that the gravitational force exerted by the Earth on an object above the Earth's surface varies inversely as the square of its distance from the Earth's center. Thus, an object's weight $w(x)$ is related to its distance $x$ from the Earth's center by a formula of the form

$$w(x) = \frac{k}{x^2}$$

where $k$ is a constant of proportionality that depends on the mass of the object.
(a) Use this fact and the assumption that the Earth is a sphere of radius 4000 mi to obtain the formula for $w(x)$ in Example 4.
(b) Find a formula for the weight $w(x)$ of a satellite that is $x$ mi from the Earth's surface if its weight on Earth is 6000 lb.
(c) How much work is required to lift the satellite from the surface of the Earth to an orbital position that is 1000 mi high?

**26.** (a) The formula $w(x) = k/x^2$ in Exercise 25 is applicable to all celestial bodies. Assuming that the Moon is a sphere of radius 1080 mi, find the force that the Moon exerts on an astronaut who is $x$ mi from the surface of the Moon if her weight on the Moon's surface is 20 lb.
(b) How much work is required to lift the astronaut to a point that is 10.8 mi above the Moon's surface?

**27.** The world's first commercial high-speed magnetic levitation (MAGLEV) train, a 30 km double-track project connecting Shanghai, China, to Pudong International Airport, began full revenue service in 2003. Suppose that a MAGLEV train has a mass $m = 4.00 \times 10^5$ kg and that starting at a time when the train has a speed of 20 m/s the engine applies a force of $6.40 \times 10^5$ N in the direction of motion over a distance of $3.00 \times 10^3$ m. Use the work–energy relationship (6) to find the final speed of the train.

**28.** Assume that a Mars probe of mass $m = 2.00 \times 10^3$ kg is subjected only to the force of its own engine. Starting at a time when the speed of the probe is $v = 1.00 \times 10^4$ m/s, the engine is fired continuously over a distance of $1.50 \times 10^5$ m with a constant force of $2.00 \times 10^5$ N in the direction of motion. Use the work–energy relationship (6) to find the final speed of the probe.

**29.** On August 10, 1972 a meteorite with an estimated mass of $4 \times 10^6$ kg and an estimated speed of 15 km/s skipped across the atmosphere above the western United States and Canada but fortunately did not hit the Earth. *(cont.)*

(a) Assuming that the meteorite had hit the Earth with a speed of 15 km/s, what would have been its change in kinetic energy in joules (J)?
(b) Express the energy as a multiple of the explosive energy of 1 megaton of TNT, which is $4.2 \times 10^{15}$ J.
(c) The energy associated with the Hiroshima atomic bomb was 13 kilotons of TNT. To how many such bombs would the meteorite impact have been equivalent?

**30. Writing** After reading Examples 3–5, a student classifies work problems as either "pushing/pulling" or "pumping." Describe these categories in your own words and discuss the methods used to solve each type. Give examples to illustrate that these categories are not mutually exclusive.

**31. Writing** How might you recognize that a problem can be solved by means of the work–energy relationship? That is, what sort of "givens" and "unknowns" would suggest such a solution? Discuss two or three examples.

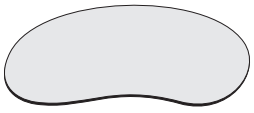
# 6.7 MOMENTS, CENTERS OF GRAVITY, AND CENTROIDS

*Suppose that a rigid physical body is acted on by a constant gravitational field. Because the body is composed of many particles, each of which is affected by gravity, the action of the gravitational field on the body consists of a large number of forces distributed over the entire body. However, it is a fact of physics that these individual forces can be replaced by a single force acting at a point called the* ***center of gravity*** *of the body. In this section we will show how integrals can be used to locate centers of gravity.*

## DENSITY AND MASS OF A LAMINA



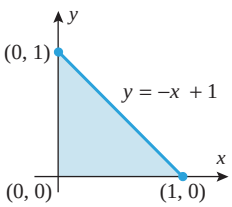
▲ **Figure 6.7.1**

Let us consider an idealized flat object that is thin enough to be viewed as a two-dimensional plane region (Figure 6.7.1). Such an object is called a ***lamina***. A lamina is called ***homogeneous*** if its composition is uniform throughout and ***inhomogeneous*** otherwise. We will consider homogeneous laminas in this section. Inhomogeneous laminas will be discussed in Chapter 14. The ***density*** of a *homogeneous* lamina is defined to be its mass per unit area. Thus, the density $\delta$ of a homogeneous lamina of mass $M$ and area $A$ is given by $\delta = M/A$. Notice that the mass $M$ of a homogeneous lamina can be expressed as

$$M = \delta A \tag{1}$$

The units in Equation (1) are consistent since mass = (mass/area) × area.

▶ **Example 1** A triangular lamina with vertices (0, 0), (0, 1), and (1, 0) has density $\delta = 3$. Find its total mass.



▲ **Figure 6.7.2**

***Solution.*** Referring to (1) and Figure 6.7.2, the mass $M$ of the lamina is

$$M = \delta A = 3 \cdot \frac{1}{2} = \frac{3}{2} \text{ (unit of mass)} \quad \blacktriangleleft$$

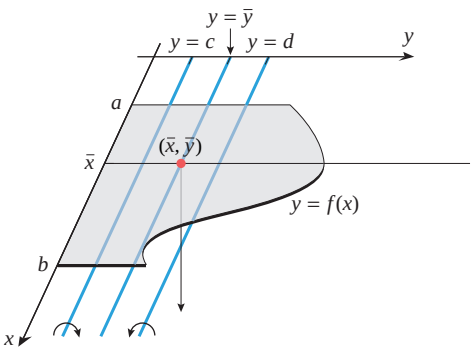
## CENTER OF GRAVITY OF A LAMINA

Assume that the acceleration due to the force of gravity is constant and acts downward, and suppose that a lamina occupies a region $R$ in a horizontal $xy$-plane. It can be shown that there exists a unique point $(\bar{x}, \bar{y})$ (which may or may not belong to $R$) such that the effect

of gravity on the lamina is "equivalent" to that of a single force acting at the point $(\bar{x}, \bar{y})$. This point is called the ***center of gravity*** of the lamina, and if it is in $R$, then the lamina will balance horizontally on the point of a support placed at $(\bar{x}, \bar{y})$. For example, the center of gravity of a homogeneous disk is at the center of the disk, and the center of gravity of a homogeneous rectangular region is at the center of the rectangle. For an irregularly shaped homogeneous lamina, locating the center of gravity requires calculus.

**6.7.1** **PROBLEM** Let $f$ be a positive continuous function on the interval $[a, b]$. Suppose that a homogeneous lamina with constant density $\delta$ occupies a region $R$ in a horizontal $xy$-plane bounded by the graphs of $y = f(x)$, $y = 0$, $x = a$, and $x = b$. Find the coordinates $(\bar{x}, \bar{y})$ of the center of gravity of the lamina.

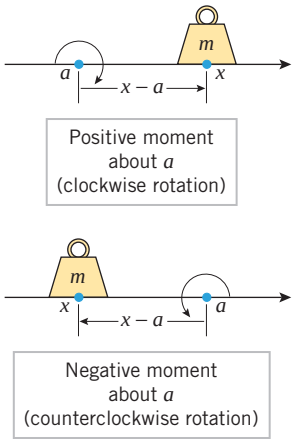
To motivate the solution, consider what happens if we try to balance the lamina on a knife-edge parallel to the $x$-axis. Suppose the lamina in Figure 6.7.3 is placed on a knife-edge along a line $y = c$ that does not pass through the center of gravity. Because the lamina behaves as if its entire mass is concentrated at the center of gravity $(\bar{x}, \bar{y})$, the lamina will be rotationally unstable and the force of gravity will cause a rotation about $y = c$. Similarly, the lamina will undergo a rotation if placed on a knife-edge along $y = d$. However, if the knife-edge runs along the line $y = \bar{y}$ through the center of gravity, the lamina will be in perfect balance. Similarly, the lamina will be in perfect balance on a knife-edge along the line $x = \bar{x}$ through the center of gravity. This suggests that the center of gravity of a lamina can be determined as the intersection of two lines of balance, one parallel to the $x$-axis and the other parallel to the $y$-axis. In order to find these lines of balance, we will need some preliminary results about rotations.



▶ **Figure 6.7.3**

Children on a seesaw learn by experience that a lighter child can balance a heavier one by sitting farther from the fulcrum or pivot point. This is because the tendency for an object to produce rotation is proportional not only to its mass but also to the distance between the object and the fulcrum. To make this more precise, consider an $x$-axis, which we view as a weightless beam. If a mass $m$ is located on the axis at $x$, then the tendency for that mass to produce a rotation of the beam about a point $a$ on the axis is measured by the following quantity, called the ***moment of m about x = a***:

$$\begin{bmatrix}\text{moment of } m \\ \text{about } a\end{bmatrix} = m(x - a)$$



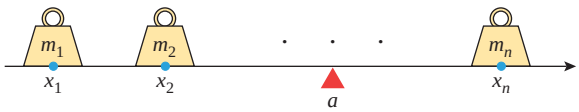
▲ **Figure 6.7.4**

The number $x - a$ is called the ***lever arm***. Depending on whether the mass is to the right or left of $a$, the lever arm is either the distance between $x$ and $a$ or the negative of this distance (Figure 6.7.4). Positive lever arms result in positive moments and clockwise rotations, and negative lever arms result in negative moments and counterclockwise rotations.

Suppose that masses $m_1, m_2, \ldots, m_n$ are located at $x_1, x_2, \ldots, x_n$ on a coordinate axis and a fulcrum is positioned at the point $a$ (Figure 6.7.5). Depending on whether the sum of the moments about $a$,

$$\sum_{k=1}^{n} m_k(x_k - a) = m_1(x_1 - a) + m_2(x_2 - a) + \cdots + m_n(x_n - a)$$

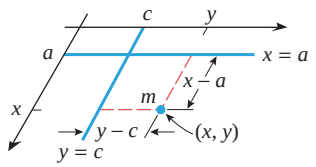
is positive, negative, or zero, a weightless beam along the axis will rotate clockwise about $a$, rotate counterclockwise about $a$, or balance perfectly. In the last case, the system of masses is said to be in ***equilibrium***.



▶ **Figure 6.7.5**

The preceding ideas can be extended to masses distributed in two-dimensional space. If we imagine the $xy$-plane to be a weightless sheet supporting a mass $m$ located at a point $(x, y)$, then the tendency for the mass to produce a rotation of the sheet about the line $x = a$ is $m(x - a)$, called the ***moment of m about x = a***, and the tendency for the mass to produce a rotation about the line $y = c$ is $m(y - c)$, called the ***moment of m about y = c*** (Figure 6.7.6). In summary,

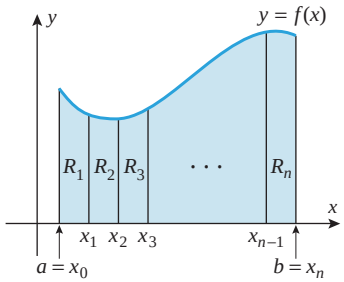
$$\begin{bmatrix}\text{moment of } m \\ \text{about the} \\ \text{line } x = a\end{bmatrix} = m(x - a) \quad \text{and} \quad \begin{bmatrix}\text{moment of } m \\ \text{about the} \\ \text{line } y = c\end{bmatrix} = m(y - c) \tag{2–3}$$



▲ **Figure 6.7.6**

If a number of masses are distributed throughout the $xy$-plane, then the plane (viewed as a weightless sheet) will balance on a knife-edge along the line $x = a$ if the sum of the moments about the line is zero. Similarly, the plane will balance on a knife-edge along the line $y = c$ if the sum of the moments about that line are zero.

We are now ready to solve Problem 6.7.1. The basic idea for solving this problem is to divide the lamina into strips whose areas may be approximated by the areas of rectangles. These area approximations, along with Formulas (2) and (3), will allow us to create a Riemann sum that approximates the moment of the lamina about a horizontal or vertical line. By taking the limit of Riemann sums we will then obtain an integral for the moment of a lamina about a horizontal or vertical line. We observe that since the lamina balances on the lines $x = \bar{x}$ and $y = \bar{y}$, the moment of the lamina about those lines should be zero. This observation will enable us to calculate $\bar{x}$ and $\bar{y}$.



▲ **Figure 6.7.7**

To implement this idea, we divide the interval $[a, b]$ into $n$ subintervals by inserting the points $x_1, x_2, \ldots, x_{n-1}$ between $a = x_0$ and $b = x_n$. This has the effect of dividing the lamina $R$ into $n$ strips $R_1, R_2, \ldots, R_n$ (Figure 6.7.7$a$). Suppose that the $k$th strip extends from $x_{k-1}$ to $x_k$ and that the width of this strip is

$$\Delta x_k = x_k - x_{k-1}$$

We will let $x_k^*$ be the midpoint of the $k$th subinterval and we will approximate $R_k$ by a rectangle of width $\Delta x_k$ and height $f(x_k^*)$. From (1), the mass $\Delta M_k$ of this rectangle is $\Delta M_k = \delta f(x_k^*)\Delta x_k$, and we will assume that the rectangle behaves as if its entire mass is concentrated at its center $(x_k^*, y_k^*) = (x_k^*, \frac{1}{2} f(x_k^*))$ (Figure 6.7.7$b$). It then follows from (2) and (3) that the moments of $R_k$ about the lines $x = \bar{x}$ and $y = \bar{y}$ may be approximated

by $(x_k^* - \bar{x})\Delta M_k$ and $(y_k^* - \bar{y})\Delta M_k$, respectively. Adding these approximations yields the following Riemann sums that approximate the moment of the entire lamina about the lines $x = \bar{x}$ and $y = \bar{y}$:

$$\sum_{k=1}^{n}(x_k^* - \bar{x})\Delta M_k = \sum_{k=1}^{n}(x_k^* - \bar{x})\delta f(x_k^*)\Delta x_k$$
$$\sum_{k=1}^{n}(y_k^* - \bar{y})\Delta M_k = \sum_{k=1}^{n}\left(\frac{f(x_k^*)}{2} - \bar{y}\right)\delta f(x_k^*)\Delta x_k$$

Taking the limits as $n$ increases and the widths of all the rectangles approach zero yields the definite integrals

$$\int_a^b (x - \bar{x})\delta f(x)\,dx \quad \text{and} \quad \int_a^b \left(\frac{f(x)}{2} - \bar{y}\right)\delta f(x)\,dx$$

that represent the moments of the lamina about the lines $x = \bar{x}$ and $y = \bar{y}$. Since the lamina balances on those lines, the moments of the lamina about those lines should be zero:

$$\int_a^b (x - \bar{x})\delta f(x)\,dx = \int_a^b \left(\frac{f(x)}{2} - \bar{y}\right)\delta f(x)\,dx = 0$$

Since $\bar{x}$ and $\bar{y}$ are constant, these equations can be rewritten as

$$\int_a^b \delta x f(x)\,dx = \bar{x}\int_a^b \delta f(x)\,dx$$
$$\int_a^b \frac{1}{2}\delta(f(x))^2\,dx = \bar{y}\int_a^b \delta f(x)\,dx$$

from which we obtain the following formulas for the center of gravity of the lamina:

***Center of Gravity $(\bar{x}, \bar{y})$ of a Lamina***

$$\bar{x} = \frac{\displaystyle\int_a^b \delta x f(x)\,dx}{\displaystyle\int_a^b \delta f(x)\,dx}, \qquad \bar{y} = \frac{\displaystyle\int_a^b \frac{1}{2}\delta\,(f(x))^2\,dx}{\displaystyle\int_a^b \delta f(x)\,dx} \tag{4–5}$$

Observe that in both formulas the denominator is the mass $M$ of the lamina. The numerator in the formula for $\bar{x}$ is denoted by $M_y$ and is called the ***first moment of the lamina about the y-axis***; the numerator of the formula for $\bar{y}$ is denoted by $M_x$ and is called the ***first moment of the lamina about the x-axis***. Thus, we can write (4) and (5) as

***Alternative Formulas for Center of Gravity $(\bar{x}, \bar{y})$ of a Lamina***

$$\bar{x} = \frac{M_y}{M} = \frac{1}{\text{mass of } R}\int_a^b \delta x f(x)\,dx \tag{6}$$

$$\bar{y} = \frac{M_x}{M} = \frac{1}{\text{mass of } R}\int_a^b \frac{1}{2}\delta\,(f(x))^2\,dx \tag{7}$$

► **Example 2** Find the center of gravity of the triangular lamina with vertices $(0, 0)$, $(0, 1)$, and $(1, 0)$ and density $\delta = 3$.

***Solution.*** The lamina is shown in Figure 6.7.2. In Example 1 we found the mass of the lamina to be

$$M = \frac{3}{2}$$

The moment of the lamina about the $y$-axis is

$$M_y = \int_0^1 \delta x f(x)\,dx = \int_0^1 3x(-x+1)\,dx$$
$$= \int_0^1 (-3x^2+3x)\,dx = \left(-x^3+\frac{3}{2}x^2\right)\Big]_0^1 = -1+\frac{3}{2} = \frac{1}{2}$$

and the moment about the $x$-axis is

$$M_x = \int_0^1 \frac{1}{2}\delta(f(x))^2\,dx = \int_0^1 \frac{3}{2}(-x+1)^2\,dx$$
$$= \int_0^1 \frac{3}{2}(x^2-2x+1)\,dx = \frac{3}{2}\left(\frac{1}{3}x^3-x^2+x\right)\Big]_0^1 = \frac{3}{2}\left(\frac{1}{3}\right) = \frac{1}{2}$$

From (6) and (7),

$$\bar{x} = \frac{M_y}{M} = \frac{1/2}{3/2} = \frac{1}{3}, \qquad \bar{y} = \frac{M_x}{M} = \frac{1/2}{3/2} = \frac{1}{3}$$

so the center of gravity is $\left(\frac{1}{3}, \frac{1}{3}\right)$. ◀

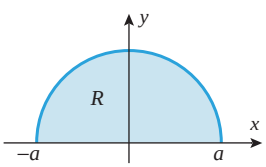
In the case of a *homogeneous* lamina, the center of gravity of a lamina occupying the region $R$ is called the ***centroid of the region R***. Since the lamina is homogeneous, $\delta$ is constant. The factor $\delta$ in (4) and (5) may thus be moved through the integral signs and canceled, and (4) and (5) can be expressed as

***Centroid of a Region R***

$$\bar{x} = \frac{\displaystyle\int_a^b x f(x)\,dx}{\displaystyle\int_a^b f(x)\,dx} = \frac{1}{\text{area of } R}\int_a^b x f(x)\,dx \tag{8}$$

$$\bar{y} = \frac{\displaystyle\int_a^b \frac{1}{2}(f(x))^2\,dx}{\displaystyle\int_a^b f(x)\,dx} = \frac{1}{\text{area of } R}\int_a^b \frac{1}{2}(f(x))^2\,dx \tag{9}$$

Since the density factor has canceled, we may interpret the centroid as a ***geometric property*** of the region, and distinguish it from the center of gravity, which is a ***physical property*** of an idealized object that occupies the region.



▲ Figure 6.7.8

▶ **Example 3** Find the centroid of the semicircular region in Figure 6.7.8.

***Solution.*** By symmetry, $\bar{x} = 0$ since the $y$-axis is obviously a line of balance. To find $\bar{y}$, first note that the equation of the semicircle is $y = f(x) = \sqrt{a^2-x^2}$. From (9),

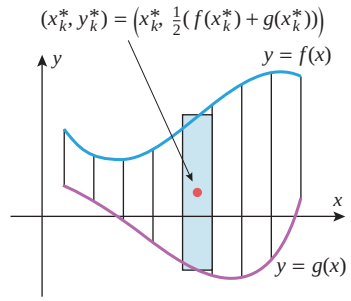
$$\bar{y} = \frac{1}{\text{area of } R}\int_{-a}^{a} \frac{1}{2}(f(x))^2\,dx = \frac{1}{\frac{1}{2}\pi a^2}\int_{-a}^{a}\frac{1}{2}(a^2-x^2)\,dx$$
$$= \frac{1}{\pi a^2}\left(a^2x-\frac{1}{3}x^3\right)\Big]_{-a}^{a}$$
$$= \frac{1}{\pi a^2}\left[\left(a^3-\frac{1}{3}a^3\right)-\left(-a^3+\frac{1}{3}a^3\right)\right]$$
$$= \frac{1}{\pi a^2}\left(\frac{4a^3}{3}\right) = \frac{4a}{3\pi}$$

so the centroid is $(0, 4a/3\pi)$. ◀

## OTHER TYPES OF REGIONS

The strategy used to find the center of gravity of the region in Problem 6.7.1 can be used to find the center of gravity of regions that are not of that form.

Consider a homogeneous lamina that occupies the region $R$ between two continuous functions $f(x)$ and $g(x)$ over the interval $[a, b]$, where $f(x) \geq g(x)$ for $a \leq x \leq b$. To find the center of gravity of this lamina we can subdivide it into $n$ strips using lines parallel to the $y$-axis. If $x_k^*$ is the midpoint of the $k$th strip, the strip can be approximated by a rectangle of width $\Delta x_k$ and height $f(x_k^*) - g(x_k^*)$. We assume that the entire mass of the $k$th rectangle is concentrated at its center $(x_k^*, y_k^*) = (x_k^*, \frac{1}{2}(f(x_k^*) + g(x_k^*)))$ (Figure 6.7.9). Continuing the argument as in the solution of Problem 6.7.1, we find that the center of gravity of the lamina is



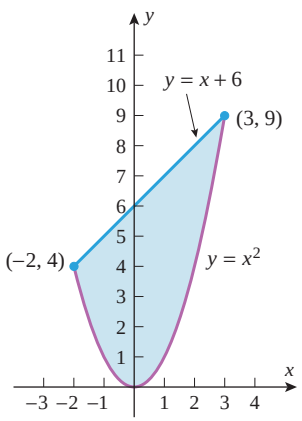
▲ Figure 6.7.9

$$\bar{x} = \frac{\displaystyle\int_a^b x(f(x) - g(x))\,dx}{\displaystyle\int_a^b (f(x) - g(x))\,dx} = \frac{1}{\text{area of } R}\int_a^b x(f(x) - g(x))\,dx \tag{10}$$

$$\bar{y} = \frac{\displaystyle\int_a^b \frac{1}{2}\left([f(x)]^2 - [g(x)]^2\right)\,dx}{\displaystyle\int_a^b (f(x) - g(x))\,dx} = \frac{1}{\text{area of } R}\int_a^b \frac{1}{2}\left([f(x)]^2 - [g(x)]^2\right)\,dx \tag{11}$$

Note that the density of the lamina does not appear in Equations (10) and (11). This reflects the fact that the centroid is a geometric property of $R$.

▶ **Example 4** Find the centroid of the region $R$ enclosed between the curves $y = x^2$ and $y = x + 6$.



▲ Figure 6.7.10

***Solution.*** To begin, we note that the two curves intersect when $x = -2$ and $x = 3$ and that $x + 6 \geq x^2$ over that interval (Figure 6.7.10). The area of $R$ is

$$\int_{-2}^{3} [(x + 6) - x^2]\,dx = \frac{125}{6}$$

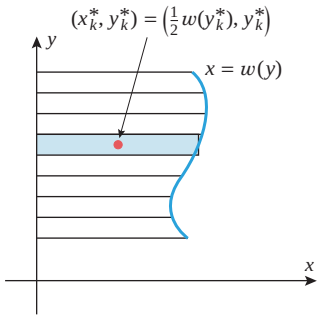
From (10) and (11),

$$\begin{aligned}\bar{x} &= \frac{1}{\text{area of } R}\int_{-2}^{3} x[(x + 6) - x^2]\,dx \\ &= \frac{6}{125}\left(\frac{1}{3}x^3 + 3x^2 - \frac{1}{4}x^4\right)\Big]_{-2}^{3} \\ &= \frac{6}{125} \cdot \frac{125}{12} = \frac{1}{2}\end{aligned}$$

and

$$\begin{aligned}\bar{y} &= \frac{1}{\text{area of } R}\int_{-2}^{3} \frac{1}{2}((x + 6)^2 - (x^2)^2)\,dx \\ &= \frac{6}{125}\int_{-2}^{3} \frac{1}{2}(x^2 + 12x + 36 - x^4)\,dx \\ &= \frac{6}{125} \cdot \frac{1}{2}\left(\frac{1}{3}x^3 + 6x^2 + 36x - \frac{1}{5}x^5\right)\Big]_{-2}^{3} \\ &= \frac{6}{125} \cdot \frac{250}{3} = 4\end{aligned}$$

so the centroid of $R$ is $\left(\frac{1}{2}, 4\right)$. ◀



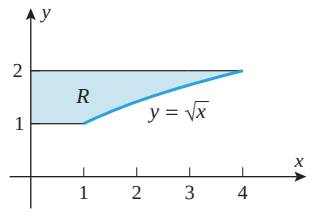
▲ Figure 6.7.11

Suppose that $w$ is a continuous function of $y$ on an interval $[c, d]$ with $w(y) \geq 0$ for $c \leq y \leq d$. Consider a lamina that occupies a region $R$ bounded above by $y = d$, below by $y = c$, on the left by the $y$-axis, and on the right by $x = w(y)$ (Figure 6.7.11). To find the center of gravity of this lamina, we note that the roles of $x$ and $y$ in Problem 6.7.1 have been reversed. We now imagine the lamina to be subdivided into $n$ strips using lines parallel to the $x$-axis. We let $y_k^*$ be the midpoint of the $k$th subinterval and approximate the strip by a rectangle of width $\Delta y_k$ and height $w(y_k^*)$. We assume that the entire mass of the $k$th rectangle is concentrated at its center $(x_k^*, y_k^*) = (\frac{1}{2}w(y_k^*), y_k^*)$ (Figure 6.7.11). Continuing the argument as in the solution of Problem 6.7.1, we find that the center of gravity of the lamina is

$$\bar{x} = \frac{\displaystyle\int_c^d \frac{1}{2}(w(y))^2\,dy}{\displaystyle\int_c^d w(y)\,dy} = \frac{1}{\text{area of } R}\int_c^d \frac{1}{2}(w(y))^2\,dy \tag{12}$$

$$\bar{y} = \frac{\displaystyle\int_c^d yw(y)\,dy}{\displaystyle\int_c^d w(y)\,dy} = \frac{1}{\text{area of } R}\int_c^d yw(y)\,dy \tag{13}$$

Once again, the absence of the density in Equations (12) and (13) reflects the geometric nature of the centroid.



▲ Figure 6.7.12

▶ **Example 5** Find the centroid of the region $R$ enclosed between the curves $y = \sqrt{x}$, $y = 1$, $y = 2$, and the $y$-axis (Figure 6.7.12).

***Solution.*** Note that $x = w(y) = y^2$ and that the area of $R$ is

$$\int_1^2 y^2\,dy = \frac{7}{3}$$

From (12) and (13),

$$\bar{x} = \frac{1}{\text{area of } R}\int_1^2 \frac{1}{2}(y^2)^2\,dy = \frac{3}{7}\cdot\frac{1}{10}y^5\Big]_1^2 = \frac{3}{7}\cdot\frac{31}{10} = \frac{93}{70}$$

$$\bar{y} = \frac{1}{\text{area of } R}\int_1^2 y(y^2)\,dy = \frac{3}{7}\cdot\frac{1}{4}y^4\Big]_1^2 = \frac{3}{7}\cdot\frac{15}{4} = \frac{45}{28}$$

so the centroid of $R$ is $(93/70, 45/28) \approx (1.329, 1.607)$. ◀

## THEOREM OF PAPPUS

The following theorem, due to the Greek mathematician Pappus, gives an important relationship between the centroid of a plane region $R$ and the volume of the solid generated when the region is revolved about a line.

**6.7.2 THEOREM (*Theorem of Pappus*)** *If $R$ is a bounded plane region and $L$ is a line that lies in the plane of $R$ such that $R$ is entirely on one side of $L$, then the volume of the solid formed by revolving $R$ about $L$ is given by*

$$\textit{volume} = (\textit{area of } R)\cdot\begin{pmatrix}\textit{distance traveled}\\ \textit{by the centroid}\end{pmatrix}$$

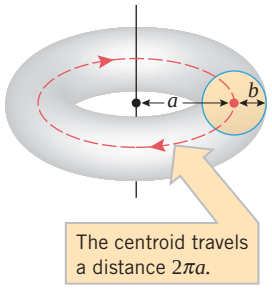
**PROOF** We prove this theorem in the special case where $L$ is the $y$-axis, the region $R$ is in the first quadrant, and the region $R$ is of the form given in Problem 6.7.1. (A more general proof will be outlined in the Exercises of Section 14.8.) In this case, the volume $V$ of the solid formed by revolving $R$ about $L$ can be found by the method of cylindrical shells (Section 6.3) to be

$$V = 2\pi \int_a^b x f(x)\,dx$$

Thus, it follows from (8) that

$$V = 2\pi \bar{x}[\text{area of } R]$$

This completes the proof since $2\pi\bar{x}$ is the distance traveled by the centroid when $R$ is revolved about the $y$-axis. ■



▲ Figure 6.7.13

▶ **Example 6** Use Pappus' Theorem to find the volume $V$ of the torus generated by revolving a circular region of radius $b$ about a line at a distance $a$ (greater than $b$) from the center of the circle (Figure 6.7.13).

***Solution.*** By symmetry, the centroid of a circular region is its center. Thus, the distance traveled by the centroid is $2\pi a$. Since the area of a circle of radius $b$ is $\pi b^2$, it follows from Pappus' Theorem that the volume of the torus is

$$V = (2\pi a)(\pi b^2) = 2\pi^2 a b^2 \quad \blacktriangleleft$$

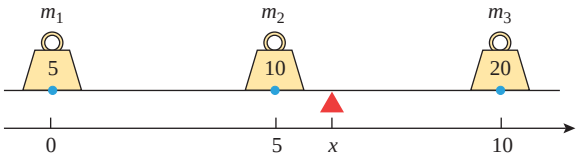
## ✔ QUICK CHECK EXERCISES 6.7 (See page 467 for answers.)

1. The total mass of a homogeneous lamina of area $A$ and density $\delta$ is _____.
2. A homogeneous lamina of mass $M$ and density $\delta$ occupies a region in the $xy$-plane bounded by the graphs of $y = f(x)$, $y = 0$, $x = a$, and $x = b$, where $f$ is a nonnegative continuous function defined on an interval $[a, b]$. The $x$-coordinate of the center of gravity of the lamina is $M_y/M$, where $M_y$ is called the _____ and is given by the integral _____.
3. Let $R$ be the region between the graphs of $y = x^2$ and $y = 2 - x$ for $0 \le x \le 1$. The area of $R$ is $\frac{7}{6}$ and the centroid of $R$ is _____.
4. If the region $R$ in Quick Check Exercise 3 is used to generate a solid $G$ by rotating $R$ about a horizontal line 6 units above its centroid, then the volume of $G$ is _____.

## EXERCISE SET 6.7 C CAS

### FOCUS ON CONCEPTS

1. Masses $m_1 = 5$, $m_2 = 10$, and $m_3 = 20$ are positioned on a weightless beam as shown in the accompanying figure.
   (a) Suppose that the fulcrum is positioned at $x = 5$. Without computing the sum of moments about 5, determine whether the sum is positive, zero, or negative. Explain.
   (b) Where should the fulcrum be placed so that the beam is in equilibrium?



▲ Figure Ex-1

**Pappus of Alexandria (4th century A.D.)** Greek mathematician. Pappus lived during the early Christian era when mathematical activity was in a period of decline. His main contributions to mathematics appeared in a series of eight books called *The Collection* (written about 340 A.D.). This work, which survives only partially, contained some original results but was devoted mostly to statements, refinements, and proofs of results by earlier mathematicians. Pappus' Theorem, stated without proof in Book VII of *The Collection*, was probably known and proved in earlier times. This result is sometimes called Guldin's Theorem in recognition of the Swiss mathematician, Paul Guldin (1577–1643), who rediscovered it independently.

**2.** Masses $m_1 = 10, m_2 = 3, m_3 = 4$, and $m$ are positioned on a weightless beam, with the fulcrum positioned at point 4, as shown in the accompanying figure.
(a) Suppose that $m = 14$. Without computing the sum of the moments about 4, determine whether the sum is positive, zero, or negative. Explain.
(b) For what value of $m$ is the beam in equilibrium?

# 6.8 FLUID PRESSURE AND FORCE

*In this section we will use the integration tools developed in the preceding chapter to study the pressures and forces exerted by fluids on submerged objects.*

## WHAT IS A FLUID?

A ***fluid*** is a substance that flows to conform to the boundaries of any container in which it is placed. Fluids include *liquids*, such as water, oil, and mercury, as well as *gases*, such as helium, oxygen, and air. The study of fluids falls into two categories: *fluid statics* (the study of fluids at rest) and *fluid dynamics* (the study of fluids in motion). In this section we will be concerned only with fluid statics; toward the end of this text we will investigate problems in fluid dynamics.

## THE CONCEPT OF PRESSURE

Brand X Pictures/Getty Images, Inc.

*Snowshoes prevent the woman from sinking by spreading her weight over a large area to reduce her pressure on the snow.*

The effect that a force has on an object depends on how that force is spread over the surface of the object. For example, when you walk on soft snow with boots, the weight of your body crushes the snow and you sink into it. However, if you put on a pair of snowshoes to spread the weight of your body over a greater surface area, then the weight of your body has less of a crushing effect on the snow. The concept that accounts for both the magnitude of a force and the area over which it is applied is called *pressure*.

**6.8.1 DEFINITION** If a force of magnitude $F$ is applied to a surface of area $A$, then we define the ***pressure*** $P$ exerted by the force on the surface to be

$$P = \frac{F}{A} \tag{1}$$

It follows from this definition that pressure has units of force per unit area. The most common units of pressure are newtons per square meter ($N/m^2$) in SI and pounds per square inch ($lb/in^2$) or pounds per square foot ($lb/ft^2$) in the BE system. As indicated in Table 6.8.1, one newton per square meter is called a *pascal* (Pa). A pressure of 1 Pa is quite small ($1\ Pa = 1.45 \times 10^{-4}\ lb/in^2$), so in countries using SI, tire pressure gauges are usually calibrated in kilopascals (kPa), which is 1000 pascals.

**Table 6.8.1**

UNITS OF FORCE AND PRESSURE

| SYSTEM | FORCE | ÷ | AREA | = | PRESSURE |
|---|---|---|---|---|---|
| SI | newton (N) | | square meter ($m^2$) | | pascal (Pa) |
| BE | pound (lb) | | square foot ($ft^2$) | | $lb/ft^2$ |
| BE | pound (lb) | | square inch ($in^2$) | | $lb/in^2$ (psi) |

CONVERSION FACTORS:

$1\ Pa \approx 1.45 \times 10^{-4}\ lb/in^2 \approx 2.09 \times 10^{-2}\ lb/ft^2$

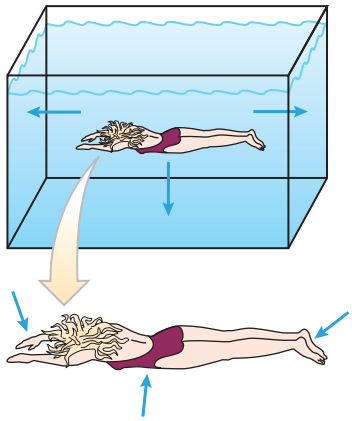
$1\ lb/in^2 \approx 6.89 \times 10^{3}\ Pa \qquad 1\ lb/ft^2 \approx 47.9\ Pa$

**Blaise Pascal (1623–1662)** French mathematician and scientist. Pascal's mother died when he was three years old and his father, a highly educated magistrate, personally provided the boy's early education. Although Pascal showed an inclination for science and mathematics, his father refused to tutor him in those subjects until he mastered Latin and Greek. Pascal's sister and primary biographer claimed that he independently discovered the first thirty-two propositions of Euclid without ever reading a book on geometry. (However, it is generally agreed that the story is apocryphal.) Nevertheless, the precocious Pascal published a highly respected essay on conic sections by the time he was sixteen years old. Descartes, who read the essay, thought it so brilliant that he could not believe that it was written by such a young man. By age 18 his health began to fail and until his death he was in frequent pain. However, his creativity was unimpaired.

Pascal's contributions to physics include the discovery that air pressure decreases with altitude and the principle of fluid pressure that bears his name. However, the originality of his work is questioned by some historians. Pascal made major contributions to a branch of mathematics called "projective geometry," and he helped to develop probability theory through a series of letters with Fermat.

In 1646, Pascal's health problems resulted in a deep emotional crisis that led him to become increasingly concerned with religious matters. Although born a Catholic, he converted to a religious doctrine called Jansenism and spent most of his final years writing on religion and philosophy.

[*Image: http://commons.wikimedia.org/wiki/File:Blaise_pascal.jpg*]



Fluid forces always act perpendicular to the surface of a submerged object.

▲ Figure 6.8.1

In this section we will be interested in pressures and forces on objects submerged in fluids. Pressures themselves have no directional characteristics, but the forces that they create always act perpendicular to the face of the submerged object. Thus, in Figure 6.8.1 the water pressure creates horizontal forces on the sides of the tank, vertical forces on the bottom of the tank, and forces that vary in direction, so as to be perpendicular to the different parts of the swimmer's body.

► **Example 1** Referring to Figure 6.8.1, suppose that the back of the swimmer's hand has a surface area of $8.4 \times 10^{-3}$ m$^2$ and that the pressure acting on it is $5.1 \times 10^4$ Pa (a realistic value near the bottom of a deep diving pool). Find the force that acts on the swimmer's hand.

***Solution.*** From (1), the force $F$ is

$$F = PA = (5.1 \times 10^4 \text{ N/m}^2)(8.4 \times 10^{-3} \text{ m}^2) \approx 4.3 \times 10^2 \text{ N}$$

This is quite a large force (nearly 100 lb in the BE system). ◄

## FLUID DENSITY

Scuba divers know that the pressure and forces on their bodies increase with the depth they dive. This is caused by the weight of the water and air above—the deeper the diver goes, the greater the weight above and so the greater the pressure and force exerted on the diver.

To calculate pressures and forces on submerged objects, we need to know something about the characteristics of the fluids in which they are submerged. For simplicity, we will assume that the fluids under consideration are *homogeneous*, by which we mean that any two samples of the fluid with the same volume have the same mass. It follows from this assumption that the mass per unit volume is a constant $\delta$ that depends on the physical characteristics of the fluid but not on the size or location of the sample; we call

$$\delta = \frac{m}{V} \tag{2}$$

the ***mass density*** of the fluid. Sometimes it is more convenient to work with weight per unit volume than with mass per unit volume. Thus, we define the ***weight density*** $\rho$ of a fluid to be

$$\rho = \frac{w}{V} \tag{3}$$

where $w$ is the weight of a fluid sample of volume $V$. Thus, if the weight density of a fluid is known, then the weight $w$ of a fluid sample of volume $V$ can be computed from the formula $w = \rho V$. Table 6.8.2 shows some typical weight densities.

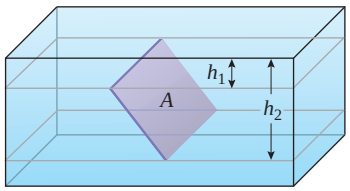
**Table 6.8.2**

| WEIGHT DENSITIES | |
|---|---|
| SI | N/m$^3$ |
| Machine oil | 4708 |
| Gasoline | 6602 |
| Fresh water | 9810 |
| Seawater | 10,045 |
| Mercury | 133,416 |
| BE SYSTEM | lb/ft$^3$ |
| Machine oil | 30.0 |
| Gasoline | 42.0 |
| Fresh water | 62.4 |
| Seawater | 64.0 |
| Mercury | 849.0 |

All densities are affected by variations in temperature and pressure. Weight densities are also affected by variations in $g$.

## FLUID PRESSURE

To calculate fluid pressures and forces we will need to make use of an experimental observation. Suppose that a flat surface of area $A$ is submerged in a homogeneous fluid of weight density $\rho$ such that the entire surface lies between depths $h_1$ and $h_2$, where $h_1 \le h_2$ (Figure 6.8.2). Experiments show that on both sides of the surface, the fluid exerts a force that is perpendicular to the surface and whose magnitude $F$ satisfies the inequalities

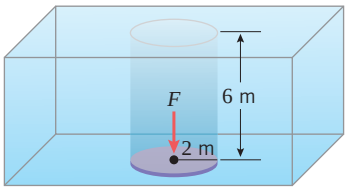


▲ Figure 6.8.2

$$\rho h_1 A \le F \le \rho h_2 A \tag{4}$$

Thus, it follows from (1) that the pressure $P = F/A$ on a given side of the surface satisfies the inequalities

$$\rho h_1 \le P \le \rho h_2 \tag{5}$$



The fluid force is the fluid pressure times the area.

▲ Figure 6.8.3

Note that it is now a straightforward matter to calculate fluid force and pressure on a flat surface that is submerged *horizontally* at depth $h$, for then $h = h_1 = h_2$ and inequalities (4) and (5) become the *equalities*

$$F = \rho h A \tag{6}$$

and

$$P = \rho h \tag{7}$$

▶ **Example 2** Find the fluid pressure and force on the top of a flat circular plate of radius 2 m that is submerged horizontally in water at a depth of 6 m (Figure 6.8.3).

***Solution.*** Since the weight density of water is $\rho = 9810\ \text{N/m}^3$, it follows from (7) that the fluid pressure is

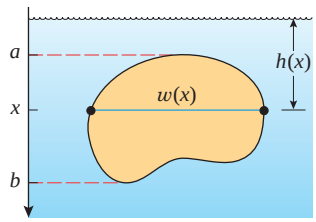
$$P = \rho h = (9810)(6) = 58{,}860\ \text{Pa}$$

and it follows from (6) that the fluid force is

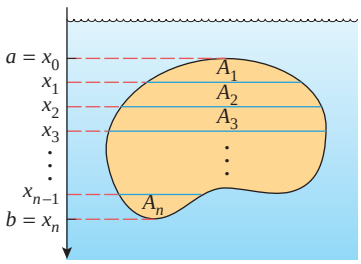
$$F = \rho h A = \rho h(\pi r^2) = (9810)(6)(4\pi) = 235{,}440\pi \approx 739{,}700\ \text{N}$$ ◀

## FLUID FORCE ON A VERTICAL SURFACE

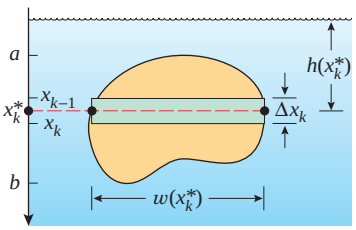
It was easy to calculate the fluid force on the horizontal plate in Example 2 because each point on the plate was at the same depth. The problem of finding the fluid force on a vertical surface is more complicated because the depth, and hence the pressure, is not constant over the surface. To find the fluid force on a vertical surface we will need calculus.



(a)



(b)



(c)

▲ Figure 6.8.4

**6.8.2 PROBLEM** Suppose that a flat surface is immersed vertically in a fluid of weight density $\rho$ and that the submerged portion of the surface extends from $x = a$ to $x = b$ along an $x$-axis whose positive direction is down (Figure 6.8.4*a*). For $a \le x \le b$, suppose that $w(x)$ is the width of the surface and that $h(x)$ is the depth of the point $x$. Define what is meant by the *fluid force* $F$ on the surface, and find a formula for computing it.

The basic idea for solving this problem is to divide the surface into horizontal strips whose areas may be approximated by areas of rectangles. These area approximations, along with inequalities (4), will allow us to create a Riemann sum that approximates the total force on the surface. By taking a limit of Riemann sums we will then obtain an integral for $F$.

To implement this idea, we divide the interval $[a, b]$ into $n$ subintervals by inserting the points $x_1, x_2, \ldots, x_{n-1}$ between $a = x_0$ and $b = x_n$. This has the effect of dividing the surface into $n$ strips of area $A_k$, $k = 1, 2, \ldots, n$ (Figure 6.8.4*b*). It follows from (4) that the force $F_k$ on the $k$th strip satisfies the inequalities

$$\rho h(x_{k-1}) A_k \le F_k \le \rho h(x_k) A_k$$

or, equivalently,

$$h(x_{k-1}) \le \frac{F_k}{\rho A_k} \le h(x_k)$$

Since the depth function $h(x)$ increases linearly, there must exist a point $x_k^*$ between $x_{k-1}$ and $x_k$ such that

$$h(x_k^*) = \frac{F_k}{\rho A_k}$$

or, equivalently,

$$F_k = \rho h(x_k^*) A_k$$

We now approximate the area $A_k$ of the $k$th strip of the surface by the area of a rectangle of width $w(x_k^*)$ and height $\Delta x_k = x_k - x_{k-1}$ (Figure 6.8.4*c*). It follows that $F_k$ may be approximated as

$$F_k = \rho h(x_k^*)A_k \approx \rho h(x_k^*) \cdot \underbrace{w(x_k^*)\Delta x_k}_{\text{Area of rectangle}}$$

Adding these approximations yields the following Riemann sum that approximates the total force $F$ on the surface:

$$F = \sum_{k=1}^{n} F_k \approx \sum_{k=1}^{n} \rho h(x_k^*) w(x_k^*) \Delta x_k$$

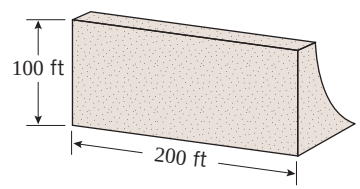
Taking the limit as $n$ increases and the widths of all the subintervals approach zero yields the definite integral

$$F = \lim_{\max \Delta x_k \to 0} \sum_{k=1}^{n} \rho h(x_k^*) w(x_k^*) \Delta x_k = \int_a^b \rho h(x) w(x)\, dx$$

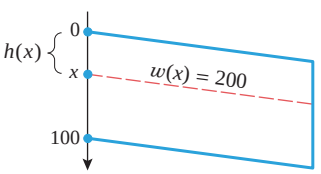
In summary, we have the following result.

**6.8.3 DEFINITION** Suppose that a flat surface is immersed vertically in a fluid of weight density $\rho$ and that the submerged portion of the surface extends from $x = a$ to $x = b$ along an $x$-axis whose positive direction is down (Figure 6.8.4*a*). For $a \le x \le b$, suppose that $w(x)$ is the width of the surface and that $h(x)$ is the depth of the point $x$. Then we define the ***fluid force*** $F$ on the surface to be

$$F = \int_a^b \rho h(x) w(x)\, dx \tag{8}$$



(*a*)



(*b*)

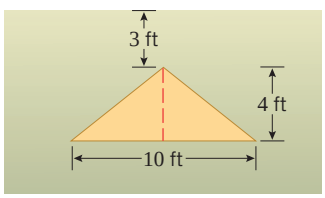
▲ **Figure 6.8.5**

▶ **Example 3** The face of a dam is a vertical rectangle of height 100 ft and width 200 ft (Figure 6.8.5*a*). Find the total fluid force exerted on the face when the water surface is level with the top of the dam.

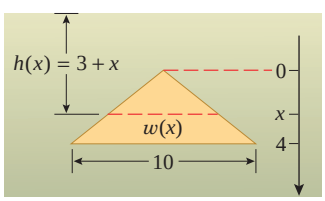
***Solution.*** Introduce an $x$-axis with its origin at the water surface as shown in Figure 6.8.5*b*. At a point $x$ on this axis, the width of the dam in feet is $w(x) = 200$ and the depth in feet is $h(x) = x$. Thus, from (8) with $\rho = 62.4$ lb/ft$^3$ (the weight density of water) we obtain as the total force on the face

$$F = \int_0^{100} (62.4)(x)(200)\, dx = 12{,}480 \int_0^{100} x\, dx$$

$$= 12{,}480 \left. \frac{x^2}{2} \right]_0^{100} = 62{,}400{,}000 \text{ lb} \quad \blacktriangleleft$$



(*a*)



(*b*)

▲ **Figure 6.8.6**

▶ **Example 4** A plate in the form of an isosceles triangle with base 10 ft and altitude 4 ft is submerged vertically in machine oil as shown in Figure 6.8.6*a*. Find the fluid force $F$ against the plate surface if the oil has weight density $\rho = 30$ lb/ft$^3$.

***Solution.*** Introduce an $x$-axis as shown in Figure 6.8.6*b*. By similar triangles, the width of the plate, in feet, at a depth of $h(x) = (3 + x)$ ft satisfies

$$\frac{w(x)}{10} = \frac{x}{4}, \quad \text{so} \quad w(x) = \frac{5}{2}x$$

Thus, it follows from (8) that the force on the plate is

$$F = \int_a^b \rho h(x) w(x)\, dx = \int_0^4 (30)(3+x)\left(\frac{5}{2}x\right) dx$$

$$= 75\int_0^4 (3x + x^2)\, dx = 75\left[\frac{3x^2}{2} + \frac{x^3}{3}\right]_0^4 = 3400 \text{ lb} \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 6.8 (See page 473 for answers.)

1. The pressure unit equivalent to a newton per square meter ($N/m^2$) is called a _____. The pressure unit psi stands for _____.
2. Given that the weight density of water is 9810 $N/m^3$, the fluid pressure on a rectangular 2 m × 3 m flat plate submerged horizontally in water at a depth of 10 m is _____. The fluid force on the plate is _____.
3. Suppose that a flat surface is immersed vertically in a fluid of weight density $\rho$ and that the submerged portion of the surface extends from $x = a$ to $x = b$ along an $x$-axis whose positive direction is down. If, for $a \le x \le b$, the surface has width $w(x)$ and depth $h(x)$, then the fluid force on the surface is $F =$ _____.
4. A rectangular plate 2 m wide and 3 m high is submerged vertically in water so that the top of the plate is 5 m below the water surface. An integral expression for the force of the water on the plate surface is $F =$ _____.

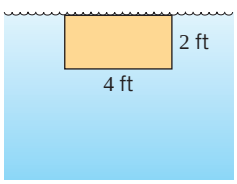
## EXERCISE SET 6.8

In this exercise set, refer to Table 6.8.2 for weight densities of fluids, where needed. ■

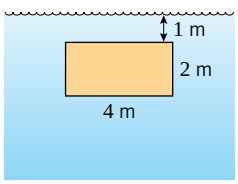
1. A flat rectangular plate is submerged horizontally in water.
   (a) Find the force (in lb) and the pressure (in $lb/ft^2$) on the top surface of the plate if its area is 100 $ft^2$ and the surface is at a depth of 5 ft.
   (b) Find the force (in N) and the pressure (in Pa) on the top surface of the plate if its area is 25 $m^2$ and the surface is at a depth of 10 m.
2. (a) Find the force (in N) on the deck of a sunken ship if its area is 160 $m^2$ and the pressure acting on it is $6.0 \times 10^5$ Pa.
   (b) Find the force (in lb) on a diver's face mask if its area is 60 $in^2$ and the pressure acting on it is 100 $lb/in^2$.

**3–8** The flat surfaces shown are submerged vertically in water. Find the fluid force against each surface. ■

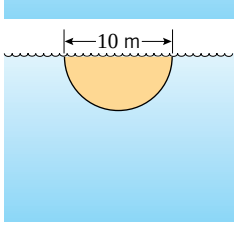
3.



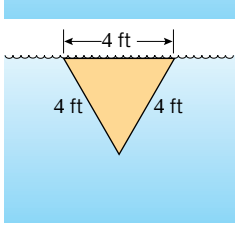
4.



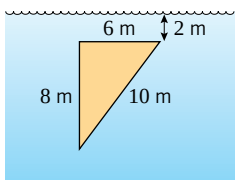
5.



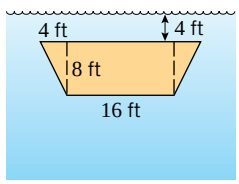
6.



7.



8.



9. Suppose that a flat surface is immersed vertically in a fluid of weight density $\rho$. If $\rho$ is doubled, is the force on the plate also doubled? Explain your reasoning.
10. An oil tank is shaped like a right circular cylinder of diameter 4 ft. Find the total fluid force against one end when the axis is horizontal and the tank is half filled with oil of weight density 50 $lb/ft^3$.
11. A square plate of side $a$ feet is dipped in a liquid of weight density $\rho$ $lb/ft^3$. Find the fluid force on the plate if a vertex is at the surface and a diagonal is perpendicular to the surface.

**12–15 True–False** Determine whether the statement is true or false. Explain your answer. ■

12. In the International System of Units, pressure and force have the same units.
13. In a cylindrical water tank (with vertical axis), the fluid force on the base of the tank is equal to the weight of water in the tank.
14. In a rectangular water tank, the fluid force on any side of the tank must be less than the fluid force on the base of the tank.

**15.** In any water tank with a flat base, no matter what the shape of the tank, the fluid force on the base is at most equal to the weight of water in the tank.

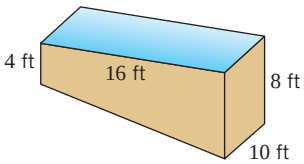
**16–19** Formula (8) gives the fluid force on a flat surface immersed vertically in a fluid. More generally, if a flat surface is immersed so that it makes an angle of $0 \le \theta < \pi/2$ with the vertical, then the fluid force on the surface is given by

$$F = \int_a^b \rho h(x) w(x) \sec\theta \, dx$$

Use this formula in these exercises. ■

**16.** Derive the formula given above for the fluid force on a flat surface immersed at an angle in a fluid.

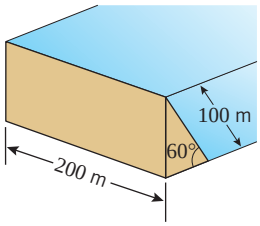
**17.** The accompanying figure shows a rectangular swimming pool whose bottom is an inclined plane. Find the fluid force on the bottom when the pool is filled to the top.



◀ **Figure Ex-17**

**18.** By how many feet should the water in the pool of Exercise 17 be lowered in order for the force on the bottom to be reduced by a factor of $\frac{1}{2}$?

**19.** The accompanying figure shows a dam whose face is an inclined rectangle. Find the fluid force on the face when the water is level with the top of this dam.



◀ **Figure Ex-19**

**20.** An observation window on a submarine is a square with 2 ft sides. Using $\rho_0$ for the weight density of seawater, find the fluid force on the window when the submarine has descended so that the window is vertical and its top is at a depth of $h$ feet.

**FOCUS ON CONCEPTS**

**21.** (a) Show: If the submarine in Exercise 20 descends vertically at a constant rate, then the fluid force on the window increases at a constant rate.

(b) At what rate is the force on the window increasing if the submarine is descending vertically at 20 ft/min?

**22.** (a) Let $D = D_a$ denote a disk of radius $a$ submerged in a fluid of weight density $\rho$ such that the center of $D$ is $h$ units below the surface of the fluid. For each value of $r$ in the interval $(0, a]$, let $D_r$ denote the disk of radius $r$ that is concentric with $D$. Select a side of the disk $D$ and define $P(r)$ to be the fluid pressure on the chosen side of $D_r$. Use (5) to prove that

$$\lim_{r \to 0^+} P(r) = \rho h$$

(b) Explain why the result in part (a) may be interpreted to mean that *fluid pressure at a given depth is the same in all directions*. (This statement is one version of a result known as ***Pascal's Principle***.)

**23.** **Writing** Suppose that we model the Earth's atmosphere as a "fluid." Atmospheric pressure at sea level is $P = 14.7$ lb/in$^2$ and the weight density of air at sea level is about $\rho = 4.66 \times 10^{-5}$ lb/in$^3$. With these numbers, what would Formula (7) yield as the height of the atmosphere above the Earth? Do you think this answer is reasonable? If not, explain how we might modify our assumptions to yield a more plausible answer.

**24.** **Writing** Suppose that the weight density $\rho$ of a fluid is a function $\rho = \rho(x)$ of the depth $x$ within the fluid. How do you think that Formula (7) for fluid pressure will need to be modified? Support your answer with plausible arguments.

## ✔ QUICK CHECK ANSWERS 6.8

**1.** pascal; pounds per square inch **2.** 98,100 Pa; 588,600 N **3.** $\int_a^b \rho h(x) w(x)\, dx$ **4.** $\int_0^3 9810\,[(5+x)2]\, dx$

# 6.9 HYPERBOLIC FUNCTIONS AND HANGING CABLES

*In this section we will study certain combinations of $e^x$ and $e^{-x}$, called "hyperbolic functions." These functions, which arise in various engineering applications, have many properties in common with the trigonometric functions. This similarity is somewhat surprising, since there is little on the surface to suggest that there should be any relationship between exponential and trigonometric functions. This is because the relationship occurs within the context of complex numbers, a topic which we will leave for more advanced courses.*

## DEFINITIONS OF HYPERBOLIC FUNCTIONS

To introduce the hyperbolic functions, observe from Exercise 65 in Section 0.2 that the function $e^x$ can be expressed in the following way as the sum of an even function and an odd function:

$$e^x = \underbrace{\frac{e^x + e^{-x}}{2}}_{\text{Even}} + \underbrace{\frac{e^x - e^{-x}}{2}}_{\text{Odd}}$$

These functions are sufficiently important that there are names and notation associated with them: the odd function is called the *hyperbolic sine* of $x$ and the even function is called the *hyperbolic cosine* of $x$. They are denoted by

$$\sinh x = \frac{e^x - e^{-x}}{2} \quad \text{and} \quad \cosh x = \frac{e^x + e^{-x}}{2}$$

where sinh is pronounced "cinch" and cosh rhymes with "gosh." From these two building blocks we can create four more functions to produce the following set of six ***hyperbolic functions***.

**6.9.1 DEFINITION**

| | |
|---|---|
| ***Hyperbolic sine*** | $\sinh x = \dfrac{e^x - e^{-x}}{2}$ |
| ***Hyperbolic cosine*** | $\cosh x = \dfrac{e^x + e^{-x}}{2}$ |
| ***Hyperbolic tangent*** | $\tanh x = \dfrac{\sinh x}{\cosh x} = \dfrac{e^x - e^{-x}}{e^x + e^{-x}}$ |
| ***Hyperbolic cotangent*** | $\coth x = \dfrac{\cosh x}{\sinh x} = \dfrac{e^x + e^{-x}}{e^x - e^{-x}}$ |
| ***Hyperbolic secant*** | $\operatorname{sech} x = \dfrac{1}{\cosh x} = \dfrac{2}{e^x + e^{-x}}$ |
| ***Hyperbolic cosecant*** | $\operatorname{csch} x = \dfrac{1}{\sinh x} = \dfrac{2}{e^x - e^{-x}}$ |

The terms "tanh," "sech," and "csch" are pronounced "tanch," "seech," and "coseech," respectively.

**TECHNOLOGY MASTERY**

Computer algebra systems have built-in capabilities for evaluating hyperbolic functions directly, but some calculators do not. However, if you need to evaluate a hyperbolic function on a calculator, you can do so by expressing it in terms of exponential functions, as in Example 1.

**▶ Example 1**

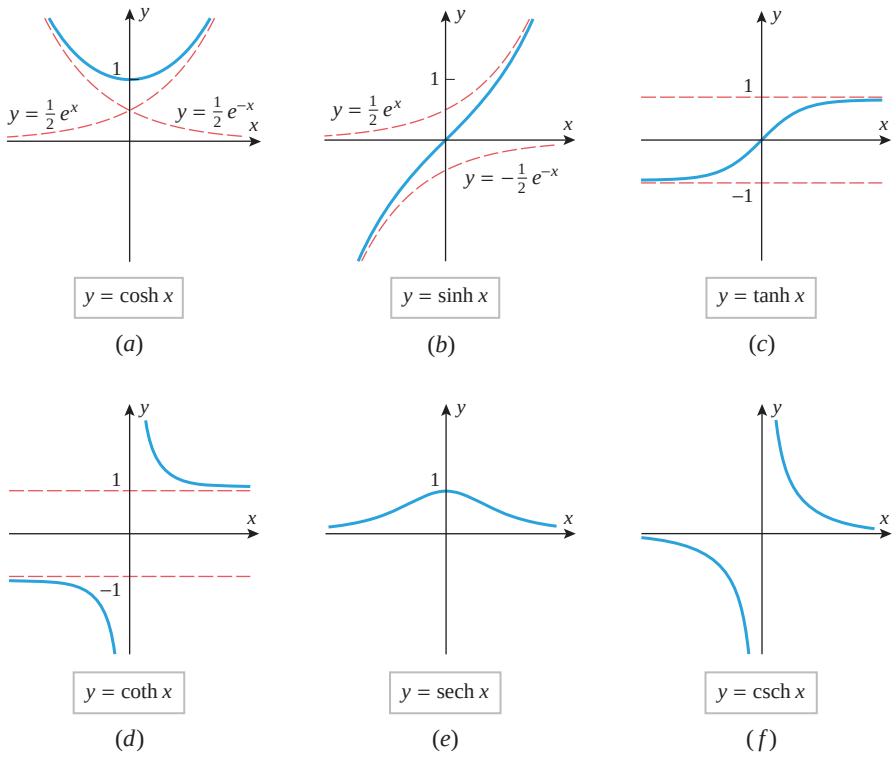
$$\sinh 0 = \frac{e^0 - e^{-0}}{2} = \frac{1 - 1}{2} = 0$$

$$\cosh 0 = \frac{e^0 + e^{-0}}{2} = \frac{1 + 1}{2} = 1$$

$$\sinh 2 = \frac{e^2 - e^{-2}}{2} \approx 3.6269 \quad \blacktriangleleft$$

## GRAPHS OF THE HYPERBOLIC FUNCTIONS

The graphs of the hyperbolic functions, which are shown in Figure 6.9.1, can be generated with a graphing utility, but it is worthwhile to observe that the general shape of the graph of $y = \cosh x$ can be obtained by sketching the graphs of $y = \frac{1}{2}e^x$ and $y = \frac{1}{2}e^{-x}$ separately and adding the corresponding $y$-coordinates [see part $(a)$ of the figure]. Similarly, the general shape of the graph of $y = \sinh x$ can be obtained by sketching the graphs of $y = \frac{1}{2}e^x$ and $y = -\frac{1}{2}e^{-x}$ separately and adding corresponding $y$-coordinates [see part $(b)$ of the figure].



▲ **Figure 6.9.1**

Glen Allison/Stone/Getty Images

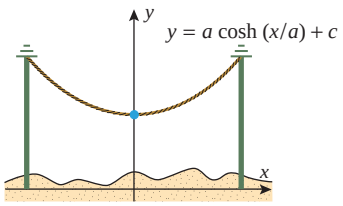
*The design of the Gateway Arch in St. Louis is based on an inverted hyperbolic cosine curve (Exercise 73).*

Observe that $\sinh x$ has a domain of $(-\infty, +\infty)$ and a range of $(-\infty, +\infty)$, whereas $\cosh x$ has a domain of $(-\infty, +\infty)$ and a range of $[1, +\infty)$. Observe also that $y = \frac{1}{2}e^x$ and $y = \frac{1}{2}e^{-x}$ are ***curvilinear asymptotes*** for $y = \cosh x$ in the sense that the graph of $y = \cosh x$ gets closer and closer to the graph of $y = \frac{1}{2}e^x$ as $x \to +\infty$ and gets closer and closer to the graph of $y = \frac{1}{2}e^{-x}$ as $x \to -\infty$. (See Section 4.3.) Similarly, $y = \frac{1}{2}e^x$ is a curvilinear asymptote for $y = \sinh x$ as $x \to +\infty$ and $y = -\frac{1}{2}e^{-x}$ is a curvilinear asymptote as $x \to -\infty$. Other properties of the hyperbolic functions are explored in the exercises.

## HANGING CABLES AND OTHER APPLICATIONS

Hyperbolic functions arise in vibratory motions inside elastic solids and more generally in many problems where mechanical energy is gradually absorbed by a surrounding medium. They also occur when a homogeneous, flexible cable is suspended between two points, as with a telephone line hanging between two poles. Such a cable forms a curve, called a ***catenary*** (from the Latin *catena*, meaning "chain"). If, as in Figure 6.9.2, a coordinate system is introduced so that the low point of the cable lies on the $y$-axis, then it can be shown using principles of physics that the cable has an equation of the form

$$y = a \cosh\left(\frac{x}{a}\right) + c$$



▲ Figure 6.9.2

where the parameters $a$ and $c$ are determined by the distance between the poles and the composition of the cable.

## HYPERBOLIC IDENTITIES

The hyperbolic functions satisfy various identities that are similar to identities for trigonometric functions. The most fundamental of these is

$$\cosh^2 x - \sinh^2 x = 1 \tag{1}$$

which can be proved by writing

$$\begin{aligned}\cosh^2 x - \sinh^2 x &= (\cosh x + \sinh x)(\cosh x - \sinh x)\\ &= \left(\frac{e^x + e^{-x}}{2} + \frac{e^x - e^{-x}}{2}\right)\left(\frac{e^x + e^{-x}}{2} - \frac{e^x - e^{-x}}{2}\right)\\ &= e^x \cdot e^{-x} = 1\end{aligned}$$

Larry Auippy/Mira.com/Digital Railroad, Inc.

*A flexible cable suspended between two poles forms a catenary.*

Other hyperbolic identities can be derived in a similar manner or, alternatively, by performing algebraic operations on known identities. For example, if we divide (1) by $\cosh^2 x$, we obtain

$$1 - \tanh^2 x = \operatorname{sech}^2 x$$

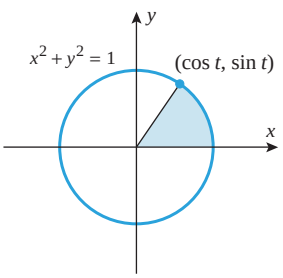
and if we divide (1) by $\sinh^2 x$, we obtain

$$\coth^2 x - 1 = \operatorname{csch}^2 x$$

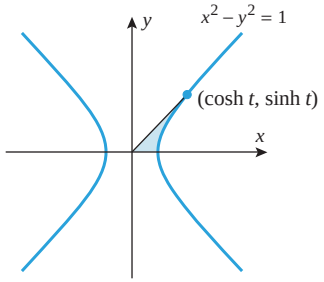
The following theorem summarizes some of the more useful hyperbolic identities. The proofs of those not already obtained are left as exercises.

**6.9.2 THEOREM**

| | |
|---|---|
| $\cosh x + \sinh x = e^x$ | $\sinh(x + y) = \sinh x \cosh y + \cosh x \sinh y$ |
| $\cosh x - \sinh x = e^{-x}$ | $\cosh(x + y) = \cosh x \cosh y + \sinh x \sinh y$ |
| $\cosh^2 x - \sinh^2 x = 1$ | $\sinh(x - y) = \sinh x \cosh y - \cosh x \sinh y$ |
| $1 - \tanh^2 x = \operatorname{sech}^2 x$ | $\cosh(x - y) = \cosh x \cosh y - \sinh x \sinh y$ |
| $\coth^2 x - 1 = \operatorname{csch}^2 x$ | $\sinh 2x = 2 \sinh x \cosh x$ |
| $\cosh(-x) = \cosh x$ | $\cosh 2x = \cosh^2 x + \sinh^2 x$ |
| $\sinh(-x) = -\sinh x$ | $\cosh 2x = 2 \sinh^2 x + 1 = 2 \cosh^2 x - 1$ |



(*a*)



(*b*)

▲ Figure 6.9.3

## WHY THEY ARE CALLED HYPERBOLIC FUNCTIONS

Recall that the parametric equations

$$x = \cos t, \quad y = \sin t \qquad (0 \le t \le 2\pi)$$

represent the unit circle $x^2 + y^2 = 1$ (Figure 6.9.3*a*), as may be seen by writing

$$x^2 + y^2 = \cos^2 t + \sin^2 t = 1$$

If $0 \le t \le 2\pi$, then the parameter $t$ can be interpreted as the angle in radians from the positive $x$-axis to the point $(\cos t, \sin t)$ or, alternatively, as twice the shaded area of the sector in Figure 6.9.3*a* (verify). Analogously, the parametric equations

$$x = \cosh t, \quad y = \sinh t \qquad (-\infty < t < +\infty)$$

represent a portion of the curve $x^2 - y^2 = 1$, as may be seen by writing

$$x^2 - y^2 = \cosh^2 t - \sinh^2 t = 1$$

and observing that $x = \cosh t > 0$. This curve, which is shown in Figure 6.9.3*b*, is the right half of a larger curve called the ***unit hyperbola***; this is the reason why the functions in this section are called *hyperbolic* functions. It can be shown that if $t \geq 0$, then the parameter $t$ can be interpreted as twice the shaded area in Figure 6.9.3*b*. (We omit the details.)

## DERIVATIVE AND INTEGRAL FORMULAS

Derivative formulas for $\sinh x$ and $\cosh x$ can be obtained by expressing these functions in terms of $e^x$ and $e^{-x}$:

$$\frac{d}{dx}[\sinh x] = \frac{d}{dx}\left[\frac{e^x - e^{-x}}{2}\right] = \frac{e^x + e^{-x}}{2} = \cosh x$$

$$\frac{d}{dx}[\cosh x] = \frac{d}{dx}\left[\frac{e^x + e^{-x}}{2}\right] = \frac{e^x - e^{-x}}{2} = \sinh x$$

Derivatives of the remaining hyperbolic functions can be obtained by expressing them in terms of sinh and cosh and applying appropriate identities. For example,

$$\frac{d}{dx}[\tanh x] = \frac{d}{dx}\left[\frac{\sinh x}{\cosh x}\right] = \frac{\cosh x \dfrac{d}{dx}[\sinh x] - \sinh x \dfrac{d}{dx}[\cosh x]}{\cosh^2 x}$$

$$= \frac{\cosh^2 x - \sinh^2 x}{\cosh^2 x} = \frac{1}{\cosh^2 x} = \operatorname{sech}^2 x$$

The following theorem provides a complete list of the generalized derivative formulas and corresponding integration formulas for the hyperbolic functions.

**6.9.3 THEOREM**

| | |
|---|---|
| $\dfrac{d}{dx}[\sinh u] = \cosh u \dfrac{du}{dx}$ | $\displaystyle\int \cosh u\, du = \sinh u + C$ |
| $\dfrac{d}{dx}[\cosh u] = \sinh u \dfrac{du}{dx}$ | $\displaystyle\int \sinh u\, du = \cosh u + C$ |
| $\dfrac{d}{dx}[\tanh u] = \operatorname{sech}^2 u \dfrac{du}{dx}$ | $\displaystyle\int \operatorname{sech}^2 u\, du = \tanh u + C$ |
| $\dfrac{d}{dx}[\coth u] = -\operatorname{csch}^2 u \dfrac{du}{dx}$ | $\displaystyle\int \operatorname{csch}^2 u\, du = -\coth u + C$ |
| $\dfrac{d}{dx}[\operatorname{sech} u] = -\operatorname{sech} u \tanh u \dfrac{du}{dx}$ | $\displaystyle\int \operatorname{sech} u \tanh u\, du = -\operatorname{sech} u + C$ |
| $\dfrac{d}{dx}[\operatorname{csch} u] = -\operatorname{csch} u \coth u \dfrac{du}{dx}$ | $\displaystyle\int \operatorname{csch} u \coth u\, du = -\operatorname{csch} u + C$ |

### ▶ Example 2

$$\frac{d}{dx}[\cosh(x^3)] = \sinh(x^3) \cdot \frac{d}{dx}[x^3] = 3x^2 \sinh(x^3)$$

$$\frac{d}{dx}[\ln(\tanh x)] = \frac{1}{\tanh x} \cdot \frac{d}{dx}[\tanh x] = \frac{\operatorname{sech}^2 x}{\tanh x} \quad \blacktriangleleft$$

**▶ Example 3**

$$\int \sinh^5 x \cosh x \, dx = \tfrac{1}{6}\sinh^6 x + C \qquad \begin{matrix} u = \sinh x \\ du = \cosh x \, dx \end{matrix}$$

$$\int \tanh x \, dx = \int \frac{\sinh x}{\cosh x}\, dx$$

$$= \ln|\cosh x| + C \qquad \begin{matrix} u = \cosh x \\ du = \sinh x \, dx \end{matrix}$$

$$= \ln(\cosh x) + C$$

We were justified in dropping the absolute value signs since $\cosh x > 0$ for all $x$. ◀

**▶ Example 4** A 100 ft wire is attached at its ends to the tops of two 50 ft poles that are positioned 90 ft apart. How high above the ground is the middle of the wire?

***Solution.*** From above, the wire forms a catenary curve with equation

$$y = a\cosh\left(\frac{x}{a}\right) + c$$

where the origin is on the ground midway between the poles. Using Formula (4) of Section 6.4 for the length of the catenary, we have

$$100 = \int_{-45}^{45} \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx$$

$$= 2\int_{0}^{45} \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx \qquad \text{By symmetry about the } y\text{-axis}$$

$$= 2\int_{0}^{45} \sqrt{1 + \sinh^2\left(\frac{x}{a}\right)}\, dx$$

$$= 2\int_{0}^{45} \cosh\left(\frac{x}{a}\right) dx \qquad \text{By (1) and the fact that } \cosh x > 0$$

$$= 2a\sinh\left(\frac{x}{a}\right)\Big]_0^{45} = 2a\sinh\left(\frac{45}{a}\right)$$

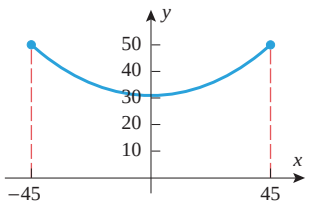
Using a calculating utility's numeric solver to solve

$$100 = 2a\sinh\left(\frac{45}{a}\right)$$

for $a$ gives $a \approx 56.01$. Then

$$50 = y(45) = 56.01\cosh\left(\frac{45}{56.01}\right) + c \approx 75.08 + c$$

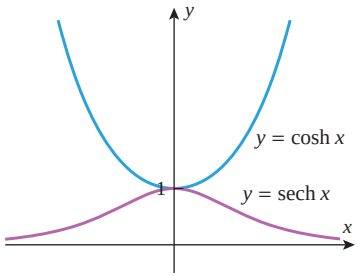
so $c \approx -25.08$. Thus, the middle of the wire is $y(0) \approx 56.01 - 25.08 = 30.93$ ft above the ground (Figure 6.9.4). ◀



▲ **Figure 6.9.4**

## INVERSES OF HYPERBOLIC FUNCTIONS

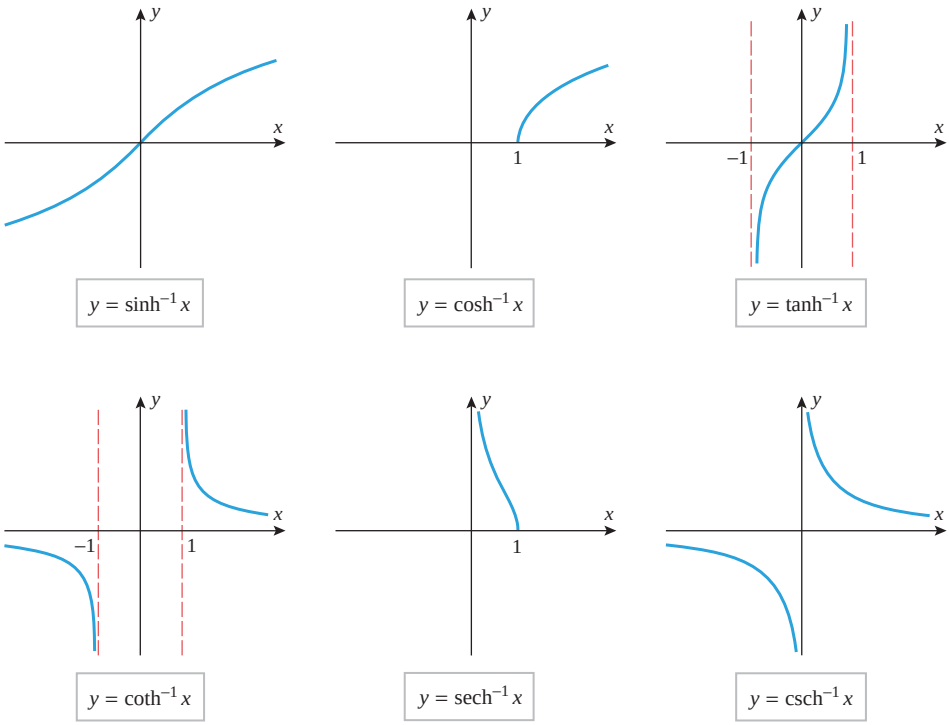
Referring to Figure 6.9.1, it is evident that the graphs of $\sinh x$, $\tanh x$, $\coth x$, and $\operatorname{csch} x$ pass the horizontal line test, but the graphs of $\cosh x$ and $\operatorname{sech} x$ do not. In the latter case, restricting $x$ to be nonnegative makes the functions invertible (Figure 6.9.5). The graphs of the six inverse hyperbolic functions in Figure 6.9.6 were obtained by reflecting the graphs of the hyperbolic functions (with the appropriate restrictions) about the line $y = x$.



With the restriction that $x \geq 0$, the curves $y = \cosh x$ and $y = \operatorname{sech} x$ pass the horizontal line test.

▲ **Figure 6.9.5**

Table 6.9.1 summarizes the basic properties of the inverse hyperbolic functions. You should confirm that the domains and ranges listed in this table agree with the graphs in Figure 6.9.6.



▶ **Figure 6.9.6**

**Table 6.9.1**

PROPERTIES OF INVERSE HYPERBOLIC FUNCTIONS

| FUNCTION | DOMAIN | RANGE | BASIC RELATIONSHIPS |
|---|---|---|---|
| $\sinh^{-1} x$ | $(-\infty, +\infty)$ | $(-\infty, +\infty)$ | $\sinh^{-1}(\sinh x) = x$ if $-\infty < x < +\infty$<br>$\sinh(\sinh^{-1} x) = x$ if $-\infty < x < +\infty$ |
| $\cosh^{-1} x$ | $[1, +\infty)$ | $[0, +\infty)$ | $\cosh^{-1}(\cosh x) = x$ if $x \geq 0$<br>$\cosh(\cosh^{-1} x) = x$ if $x \geq 1$ |
| $\tanh^{-1} x$ | $(-1, 1)$ | $(-\infty, +\infty)$ | $\tanh^{-1}(\tanh x) = x$ if $-\infty < x < +\infty$<br>$\tanh(\tanh^{-1} x) = x$ if $-1 < x < 1$ |
| $\coth^{-1} x$ | $(-\infty, -1) \cup (1, +\infty)$ | $(-\infty, 0) \cup (0, +\infty)$ | $\coth^{-1}(\coth x) = x$ if $x < 0$ or $x > 0$<br>$\coth(\coth^{-1} x) = x$ if $x < -1$ or $x > 1$ |
| $\operatorname{sech}^{-1} x$ | $(0, 1]$ | $[0, +\infty)$ | $\operatorname{sech}^{-1}(\operatorname{sech} x) = x$ if $x \geq 0$<br>$\operatorname{sech}(\operatorname{sech}^{-1} x) = x$ if $0 < x \leq 1$ |
| $\operatorname{csch}^{-1} x$ | $(-\infty, 0) \cup (0, +\infty)$ | $(-\infty, 0) \cup (0, +\infty)$ | $\operatorname{csch}^{-1}(\operatorname{csch} x) = x$ if $x < 0$ or $x > 0$<br>$\operatorname{csch}(\operatorname{csch}^{-1} x) = x$ if $x < 0$ or $x > 0$ |

## LOGARITHMIC FORMS OF INVERSE HYPERBOLIC FUNCTIONS

Because the hyperbolic functions are expressible in terms of $e^x$, it should not be surprising that the inverse hyperbolic functions are expressible in terms of natural logarithms; the next theorem shows that this is so.

**6.9.4 THEOREM** *The following relationships hold for all $x$ in the domains of the stated inverse hyperbolic functions*:

$$\sinh^{-1} x = \ln(x + \sqrt{x^2 + 1}) \qquad \cosh^{-1} x = \ln(x + \sqrt{x^2 - 1})$$

$$\tanh^{-1} x = \frac{1}{2} \ln\left(\frac{1 + x}{1 - x}\right) \qquad \coth^{-1} x = \frac{1}{2} \ln\left(\frac{x + 1}{x - 1}\right)$$

$$\operatorname{sech}^{-1} x = \ln\left(\frac{1 + \sqrt{1 - x^2}}{x}\right) \qquad \operatorname{csch}^{-1} x = \ln\left(\frac{1}{x} + \frac{\sqrt{1 + x^2}}{|x|}\right)$$

We will show how to derive the first formula in this theorem and leave the rest as exercises. The basic idea is to write the equation $x = \sinh y$ in terms of exponential functions and solve this equation for $y$ as a function of $x$. This will produce the equation $y = \sinh^{-1} x$ with $\sinh^{-1} x$ expressed in terms of natural logarithms. Expressing $x = \sinh y$ in terms of exponentials yields

$$x = \sinh y = \frac{e^y - e^{-y}}{2}$$

which can be rewritten as

$$e^y - 2x - e^{-y} = 0$$

Multiplying this equation through by $e^y$ we obtain

$$e^{2y} - 2xe^y - 1 = 0$$

and applying the quadratic formula yields

$$e^y = \frac{2x \pm \sqrt{4x^2 + 4}}{2} = x \pm \sqrt{x^2 + 1}$$

Since $e^y > 0$, the solution involving the minus sign is extraneous and must be discarded. Thus,

$$e^y = x + \sqrt{x^2 + 1}$$

Taking natural logarithms yields

$$y = \ln(x + \sqrt{x^2 + 1}) \quad \text{or} \quad \sinh^{-1} x = \ln(x + \sqrt{x^2 + 1})$$

### ▶ Example 5

$$\sinh^{-1} 1 = \ln(1 + \sqrt{1^2 + 1}) = \ln(1 + \sqrt{2}) \approx 0.8814$$

$$\tanh^{-1}\left(\frac{1}{2}\right) = \frac{1}{2} \ln\left(\frac{1 + \frac{1}{2}}{1 - \frac{1}{2}}\right) = \frac{1}{2} \ln 3 \approx 0.5493 \quad \blacktriangleleft$$

## DERIVATIVES AND INTEGRALS INVOLVING INVERSE HYPERBOLIC FUNCTIONS

Show that the derivative of the function $\sinh^{-1} x$ can also be obtained by letting $y = \sinh^{-1} x$ and then differentiating $x = \sinh y$ implicitly.

Formulas for the derivatives of the inverse hyperbolic functions can be obtained from Theorem 6.9.4. For example,

$$\frac{d}{dx}[\sinh^{-1} x] = \frac{d}{dx}[\ln(x + \sqrt{x^2+1})] = \frac{1}{x+\sqrt{x^2+1}}\left(1 + \frac{x}{\sqrt{x^2+1}}\right)$$

$$= \frac{\sqrt{x^2+1}+x}{(x+\sqrt{x^2+1})(\sqrt{x^2+1})} = \frac{1}{\sqrt{x^2+1}}$$

This computation leads to two integral formulas, a formula that involves $\sinh^{-1} x$ and an equivalent formula that involves logarithms:

$$\int \frac{dx}{\sqrt{x^2+1}} = \sinh^{-1} x + C = \ln(x + \sqrt{x^2+1}) + C$$

The following two theorems list the generalized derivative formulas and corresponding integration formulas for the inverse hyperbolic functions. Some of the proofs appear as exercises.

**6.9.5 THEOREM**

$$\frac{d}{dx}(\sinh^{-1} u) = \frac{1}{\sqrt{1+u^2}}\frac{du}{dx} \qquad \frac{d}{dx}(\coth^{-1} u) = \frac{1}{1-u^2}\frac{du}{dx}, \quad |u| > 1$$

$$\frac{d}{dx}(\cosh^{-1} u) = \frac{1}{\sqrt{u^2-1}}\frac{du}{dx}, \quad u > 1 \qquad \frac{d}{dx}(\operatorname{sech}^{-1} u) = -\frac{1}{u\sqrt{1-u^2}}\frac{du}{dx}, \quad 0 < u < 1$$

$$\frac{d}{dx}(\tanh^{-1} u) = \frac{1}{1-u^2}\frac{du}{dx}, \quad |u| < 1 \qquad \frac{d}{dx}(\operatorname{csch}^{-1} u) = -\frac{1}{|u|\sqrt{1+u^2}}\frac{du}{dx}, \quad u \neq 0$$

**6.9.6 THEOREM** *If $a > 0$, then*

$$\int \frac{du}{\sqrt{a^2+u^2}} = \sinh^{-1}\left(\frac{u}{a}\right) + C \text{ or } \ln(u + \sqrt{u^2+a^2}) + C$$

$$\int \frac{du}{\sqrt{u^2-a^2}} = \cosh^{-1}\left(\frac{u}{a}\right) + C \text{ or } \ln(u + \sqrt{u^2-a^2}) + C, \quad u > a$$

$$\int \frac{du}{a^2-u^2} = \begin{cases} \frac{1}{a}\tanh^{-1}\left(\frac{u}{a}\right) + C, & |u| < a \\ \frac{1}{a}\coth^{-1}\left(\frac{u}{a}\right) + C, & |u| > a \end{cases} \text{ or } \frac{1}{2a}\ln\left|\frac{a+u}{a-u}\right| + C, \quad |u| \neq a$$

$$\int \frac{du}{u\sqrt{a^2-u^2}} = -\frac{1}{a}\operatorname{sech}^{-1}\left|\frac{u}{a}\right| + C \text{ or } -\frac{1}{a}\ln\left(\frac{a+\sqrt{a^2-u^2}}{|u|}\right) + C, \quad 0 < |u| < a$$

$$\int \frac{du}{u\sqrt{a^2+u^2}} = -\frac{1}{a}\operatorname{csch}^{-1}\left|\frac{u}{a}\right| + C \text{ or } -\frac{1}{a}\ln\left(\frac{a+\sqrt{a^2+u^2}}{|u|}\right) + C, \quad u \neq 0$$

**▶ Example 6** Evaluate $\displaystyle\int \frac{dx}{\sqrt{4x^2-9}}, \; x > \frac{3}{2}$.

***Solution.*** Let $u = 2x$. Thus, $du = 2\,dx$ and

$$\int \frac{dx}{\sqrt{4x^2-9}} = \frac{1}{2}\int \frac{2\,dx}{\sqrt{4x^2-9}} = \frac{1}{2}\int \frac{du}{\sqrt{u^2-3^2}}$$
$$= \frac{1}{2}\cosh^{-1}\left(\frac{u}{3}\right) + C = \frac{1}{2}\cosh^{-1}\left(\frac{2x}{3}\right) + C$$

Alternatively, we can use the logarithmic equivalent of $\cosh^{-1}(2x/3)$,

$$\cosh^{-1}\left(\frac{2x}{3}\right) = \ln(2x + \sqrt{4x^2-9}) - \ln 3$$

(verify), and express the answer as

$$\int \frac{dx}{\sqrt{4x^2-9}} = \frac{1}{2}\ln(2x + \sqrt{4x^2-9}) + C \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 6.9 (See page 485 for answers.)

**1.** $\cosh x =$ _____ $\sinh x =$ _____
$\tanh x =$ _____

**2.** Complete the table.

## EXERCISE SET 6.9 Graphing Utility

**1–2** Approximate the expression to four decimal places. ■

**1.** (a) $\sinh 3$ (b) $\cosh(-2)$ (c) $\tanh(\ln 4)$
(d) $\sinh^{-1}(-2)$ (e) $\cosh^{-1} 3$ (f) $\tanh^{-1}\frac{3}{4}$

**2.** (a) $\operatorname{csch}(-1)$ (b) $\operatorname{sech}(\ln 2)$ (c) $\coth 1$
(d) $\operatorname{sech}^{-1}\frac{1}{2}$ (e) $\coth^{-1} 3$ (f) $\operatorname{csch}^{-1}(-\sqrt{3})$

**3.** Find the exact numerical value of each expression.
(a) $\sinh(\ln 3)$ (b) $\cosh(-\ln 2)$
(c) $\tanh(2\ln 5)$ (d) $\sinh(-3\ln 2)$

**4.** In each part, rewrite the expression as a ratio of polynomials.
(a) $\cosh(\ln x)$ (b) $\sinh(\ln x)$
(c) $\tanh(2\ln x)$ (d) $\cosh(-\ln x)$

**5.** In each part, a value for one of the hyperbolic functions is given at an unspecified positive number $x_0$. Use appropriate identities to find the exact values of the remaining five hyperbolic functions at $x_0$.
(a) $\sinh x_0 = 2$ (b) $\cosh x_0 = \frac{5}{4}$ (c) $\tanh x_0 = \frac{4}{5}$

**6.** Obtain the derivative formulas for $\operatorname{csch} x$, $\operatorname{sech} x$, and $\coth x$ from the derivative formulas for $\sinh x$, $\cosh x$, and $\tanh x$.

**7.** Find the derivatives of $\cosh^{-1} x$ and $\tanh^{-1} x$ by differentiating the formulas in Theorem 6.9.4.

**8.** Find the derivatives of $\sinh^{-1} x$, $\cosh^{-1} x$, and $\tanh^{-1} x$ by differentiating the equations $x = \sinh y$, $x = \cosh y$, and $x = \tanh y$ implicitly.

**9–28** Find $dy/dx$. ■

**9.** $y = \sinh(4x - 8)$ **10.** $y = \cosh(x^4)$

**11.** $y = \coth(\ln x)$

**12.** $y = \ln(\tanh 2x)$

**13.** $y = \operatorname{csch}(1/x)$

**14.** $y = \operatorname{sech}(e^{2x})$

**15.** $y = \sqrt{4x + \cosh^2(5x)}$

**16.** $y = \sinh^3(2x)$

**17.** $y = x^3 \tanh^2(\sqrt{x})$

**18.** $y = \sinh(\cos 3x)$

**19.** $y = \sinh^{-1}\left(\frac{1}{3}x\right)$

**20.** $y = \sinh^{-1}(1/x)$

**21.** $y = \ln(\cosh^{-1} x)$

**22.** $y = \cosh^{-1}(\sinh^{-1} x)$

**23.** $y = \dfrac{1}{\tanh^{-1} x}$

**24.** $y = (\coth^{-1} x)^2$

**25.** $y = \cosh^{-1}(\cosh x)$

**26.** $y = \sinh^{-1}(\tanh x)$

**27.** $y = e^x \operatorname{sech}^{-1}\sqrt{x}$

**28.** $y = (1 + x \operatorname{csch}^{-1} x)^{10}$

**29–44** Evaluate the integrals. ■

**29.** $\displaystyle\int \sinh^6 x \cosh x \, dx$

**30.** $\displaystyle\int \cosh(2x - 3)\, dx$

**31.** $\displaystyle\int \sqrt{\tanh x}\, \operatorname{sech}^2 x \, dx$

**32.** $\displaystyle\int \operatorname{csch}^2(3x)\, dx$

**33.** $\displaystyle\int \tanh x \, dx$

**34.** $\displaystyle\int \coth^2 x \operatorname{csch}^2 x \, dx$

**35.** $\displaystyle\int_{\ln 2}^{\ln 3} \tanh x \operatorname{sech}^3 x \, dx$

**36.** $\displaystyle\int_0^{\ln 3} \frac{e^x - e^{-x}}{e^x + e^{-x}}\, dx$

**37.** $\displaystyle\int \frac{dx}{\sqrt{1 + 9x^2}}$

**38.** $\displaystyle\int \frac{dx}{\sqrt{x^2 - 2}} \quad (x > \sqrt{2})$

**39.** $\displaystyle\int \frac{dx}{\sqrt{1 - e^{2x}}} \quad (x < 0)$

**40.** $\displaystyle\int \frac{\sin\theta \, d\theta}{\sqrt{1 + \cos^2\theta}}$

**41.** $\displaystyle\int \frac{dx}{x\sqrt{1 + 4x^2}}$

**42.** $\displaystyle\int \frac{dx}{\sqrt{9x^2 - 25}} \quad (x > 5/3)$

**43.** $\displaystyle\int_0^{1/2} \frac{dx}{1 - x^2}$

**44.** $\displaystyle\int_0^{\sqrt{3}} \frac{dt}{\sqrt{t^2 + 1}}$

**45–48 True–False** Determine whether the statement is true or false. Explain your answer. ■

**45.** The equation $\cosh x = \sinh x$ has no solutions.

**46.** Exactly two of the hyperbolic functions are bounded.

**47.** There is exactly one hyperbolic function $f(x)$ such that for all real numbers $a$, the equation $f(x) = a$ has a unique solution $x$.

**48.** The identities in Theorem 6.9.2 may be obtained from the corresponding trigonometric identities by replacing each trigonometric function with its hyperbolic analogue.

**49.** Find the area enclosed by $y = \sinh 2x$, $y = 0$, and $x = \ln 3$.

**50.** Find the volume of the solid that is generated when the region enclosed by $y = \operatorname{sech} x$, $y = 0$, $x = 0$, and $x = \ln 2$ is revolved about the $x$-axis.

**51.** Find the volume of the solid that is generated when the region enclosed by $y = \cosh 2x$, $y = \sinh 2x$, $x = 0$, and $x = 5$ is revolved about the $x$-axis.

**52.** Approximate the positive value of the constant $a$ such that the area enclosed by $y = \cosh ax$, $y = 0$, $x = 0$, and $x = 1$ is 2 square units. Express your answer to at least five decimal places.

**53.** Find the arc length of the catenary $y = \cosh x$ between $x = 0$ and $x = \ln 2$.

**54.** Find the arc length of the catenary $y = a\cosh(x/a)$ between $x = 0$ and $x = x_1$ $(x_1 > 0)$.

**55.** In parts (a)–(f) find the limits, and confirm that they are consistent with the graphs in Figures 6.9.1 and 6.9.6.

(a) $\displaystyle\lim_{x \to +\infty} \sinh x$ (b) $\displaystyle\lim_{x \to -\infty} \sinh x$

(c) $\displaystyle\lim_{x \to +\infty} \tanh x$ (d) $\displaystyle\lim_{x \to -\infty} \tanh x$

(e) $\displaystyle\lim_{x \to +\infty} \sinh^{-1} x$ (f) $\displaystyle\lim_{x \to 1^-} \tanh^{-1} x$

**FOCUS ON CONCEPTS**

**56.** Explain how to obtain the asymptotes for $y = \tanh x$ from the curvilinear asymptotes for $y = \cosh x$ and $y = \sinh x$.

**57.** Prove that $\sinh x$ is an odd function of $x$ and that $\cosh x$ is an even function of $x$, and check that this is consistent with the graphs in Figure 6.9.1.

**58–59** Prove the identities. ■

**58.** (a) $\cosh x + \sinh x = e^x$

(b) $\cosh x - \sinh x = e^{-x}$

(c) $\sinh(x + y) = \sinh x \cosh y + \cosh x \sinh y$

(d) $\sinh 2x = 2\sinh x \cosh x$

(e) $\cosh(x + y) = \cosh x \cosh y + \sinh x \sinh y$

(f) $\cosh 2x = \cosh^2 x + \sinh^2 x$

(g) $\cosh 2x = 2\sinh^2 x + 1$

(h) $\cosh 2x = 2\cosh^2 x - 1$

**59.** (a) $1 - \tanh^2 x = \operatorname{sech}^2 x$

(b) $\tanh(x + y) = \dfrac{\tanh x + \tanh y}{1 + \tanh x \tanh y}$

(c) $\tanh 2x = \dfrac{2\tanh x}{1 + \tanh^2 x}$

**60.** Prove:

(a) $\cosh^{-1} x = \ln(x + \sqrt{x^2 - 1}), \quad x \geq 1$

(b) $\tanh^{-1} x = \dfrac{1}{2}\ln\left(\dfrac{1 + x}{1 - x}\right), \quad -1 < x < 1.$

**61.** Use Exercise 60 to obtain the derivative formulas for $\cosh^{-1} x$ and $\tanh^{-1} x$.

**62.** Prove:

$$\operatorname{sech}^{-1} x = \cosh^{-1}(1/x), \quad 0 < x \leq 1$$
$$\coth^{-1} x = \tanh^{-1}(1/x), \quad |x| > 1$$
$$\operatorname{csch}^{-1} x = \sinh^{-1}(1/x), \quad x \neq 0$$

**63.** Use Exercise 62 to express the integral

$$\int \frac{du}{1 - u^2}$$

entirely in terms of $\tanh^{-1}$.

**64.** Show that

(a) $\dfrac{d}{dx}[\operatorname{sech}^{-1}|x|] = -\dfrac{1}{x\sqrt{1-x^2}}$

(b) $\dfrac{d}{dx}[\operatorname{csch}^{-1}|x|] = -\dfrac{1}{x\sqrt{1+x^2}}$.

**65.** In each part, find the limit.

(a) $\lim\limits_{x\to+\infty}(\cosh^{-1}x - \ln x)$ (b) $\lim\limits_{x\to+\infty}\dfrac{\cosh x}{e^x}$

**66.** Use the first and second derivatives to show that the graph of $y = \tanh^{-1}x$ is always increasing and has an inflection point at the origin.

**67.** The integration formulas for $1/\sqrt{u^2-a^2}$ in Theorem 6.9.6 are valid for $u > a$. Show that the following formula is valid for $u < -a$:

$$\int \frac{du}{\sqrt{u^2-a^2}} = -\cosh^{-1}\left(-\frac{u}{a}\right) + C \quad \text{or} \quad \ln\left|u+\sqrt{u^2-a^2}\right| + C$$

**68.** Show that $(\sinh x + \cosh x)^n = \sinh nx + \cosh nx$.

**69.** Show that

$$\int_{-a}^{a} e^{tx}\,dx = \frac{2\sinh at}{t}$$

**70.** A cable is suspended between two poles as shown in Figure 6.9.2. Assume that the equation of the curve formed by the cable is $y = a\cosh(x/a)$, where $a$ is a positive constant. Suppose that the $x$-coordinates of the points of support are $x = -b$ and $x = b$, where $b > 0$.

(a) Show that the length $L$ of the cable is given by

$$L = 2a\sinh\frac{b}{a}$$

(b) Show that the sag $S$ (the vertical distance between the highest and lowest points on the cable) is given by

$$S = a\cosh\frac{b}{a} - a$$

**71–72** These exercises refer to the hanging cable described in Exercise 70. ■

**71.** Assuming that the poles are 400 ft apart and the sag in the cable is 30 ft, approximate the length of the cable by approximating $a$. Express your final answer to the nearest tenth of a foot. [*Hint:* First let $u = 200/a$.]

**72.** Assuming that the cable is 120 ft long and the poles are 100 ft apart, approximate the sag in the cable by approximating $a$. Express your final answer to the nearest tenth of a foot. [*Hint:* First let $u = 50/a$.]

**73.** The design of the Gateway Arch in St. Louis, Missouri, by architect Eero Saarinan was implemented using equations provided by Dr. Hannskarl Badel. The equation used for the centerline of the arch was

$$y = 693.8597 - 68.7672\cosh(0.0100333x) \text{ ft}$$

for $x$ between $-299.2239$ and $299.2239$.

(a) Use a graphing utility to graph the centerline of the arch.

(b) Find the length of the centerline to four decimal places.

(c) For what values of $x$ is the height of the arch 100 ft? Round your answers to four decimal places.

(d) Approximate, to the nearest degree, the acute angle that the tangent line to the centerline makes with the ground at the ends of the arch.

**74.** Suppose that a hollow tube rotates with a constant angular velocity of $\omega$ rad/s about a horizontal axis at one end of the tube, as shown in the accompanying figure. Assume that an object is free to slide without friction in the tube while the tube is rotating. Let $r$ be the distance from the object to the pivot point at time $t \geq 0$, and assume that the object is at rest and $r = 0$ when $t = 0$. It can be shown that if the tube is horizontal at time $t = 0$ and rotating as shown in the figure, then

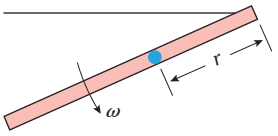
$$r = \frac{g}{2\omega^2}[\sinh(\omega t) - \sin(\omega t)]$$

during the period that the object is in the tube. Assume that $t$ is in seconds and $r$ is in meters, and use $g = 9.8$ m/s$^2$ and $\omega = 2$ rad/s.

(a) Graph $r$ versus $t$ for $0 \leq t \leq 1$.

(b) Assuming that the tube has a length of 1 m, approximately how long does it take for the object to reach the end of the tube?

(c) Use the result of part (b) to approximate $dr/dt$ at the instant that the object reaches the end of the tube.



◀ **Figure Ex-74**

**75.** The accompanying figure (on the next page) shows a person pulling a boat by holding a rope of length $a$ attached to the bow and walking along the edge of a dock. If we assume that the rope is always tangent to the curve traced by the bow of the boat, then this curve, which is called a ***tractrix***, has the property that the segment of the tangent line between the curve and the $y$-axis has a constant length $a$. It can be proved that the equation of this tractrix is

$$y = a\operatorname{sech}^{-1}\frac{x}{a} - \sqrt{a^2-x^2}$$

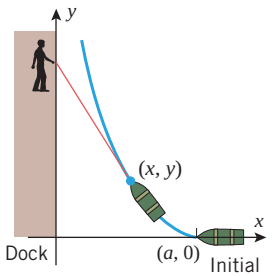
(a) Show that to move the bow of the boat to a point $(x, y)$, the person must walk a distance

$$D = a\operatorname{sech}^{-1}\frac{x}{a}$$

from the origin.

(b) If the rope has a length of 15 m, how far must the person walk from the origin to bring the boat 10 m from the dock? Round your answer to two decimal places.

(c) Find the distance traveled by the bow along the tractrix as it moves from its initial position to the point where it is 5 m from the dock.



◀ **Figure Ex-75**

**76.** **Writing** Suppose that, by analogy with the trigonometric functions, we *define* $\cosh t$ and $\sinh t$ geometrically using Figure 6.9.3*b*:

"For any real number $t$, define $x = \cosh t$ and $y = \sinh t$ to be the unique values of $x$ and $y$ such that

(i) $P(x, y)$ is on the right branch of the unit hyperbola $x^2 - y^2 = 1$;

(ii) $t$ and $y$ have the same sign (or are both 0);

(iii) the area of the region bounded by the $x$-axis, the right branch of the unit hyperbola, and the segment from the origin to $P$ is $|t|/2$."

Discuss what properties would first need to be verified in order for this to be a legitimate definition.

**77.** **Writing** Investigate what properties of $\cosh t$ and $\sinh t$ can be proved directly from the geometric definition in Exercise 76. Write a short description of the results of your investigation.

## ✔ QUICK CHECK ANSWERS 6.9

**1.** $\dfrac{e^x + e^{-x}}{2}$; $\dfrac{e^x - e^{-x}}{2}$; $\dfrac{e^x - e^{-x}}{e^x + e^{-x}}$

**2.**

| | $\cosh x$ | $\sinh x$ | $\tanh x$ | $\coth x$ | $\operatorname{sech} x$ | $\operatorname{csch} x$ |
|---|---|---|---|---|---|---|
| DOMAIN | $(-\infty, +\infty)$ | $(-\infty, +\infty)$ | $(-\infty, +\infty)$ | $(-\infty, 0) \cup (0, +\infty)$ | $(-\infty, +\infty)$ | $(-\infty, 0) \cup (0, +\infty)$ |

## CHAPTER 6 REVIEW EXERCISES

**1.** Describe the method of slicing for finding volumes, and use that method to derive an integral formula for finding volumes by the method of disks.

**2.** State an integral formula for finding a volume by the method of cylindrical shells, and use Riemann sums to derive the formula.

**3.** State an integral formula for finding the arc length of a smooth curve $y = f(x)$ over an interval $[a, b]$, and use Riemann sums to derive the formula.

**4.** State an integral formula for the work $W$ done by a variable force $F(x)$ applied in the direction of motion to an object moving from $x = a$ to $x = b$, and use Riemann sums to derive the formula.

**5.** State an integral formula for the fluid force $F$ exerted on a vertical flat surface immersed in a fluid of weight density $\rho$, and use Riemann sums to derive the formula.

**6.** Let $R$ be the region in the first quadrant enclosed by $y = x^2$, $y = 2 + x$, and $x = 0$. In each part, set up, but *do not evaluate*, an integral or a sum of integrals that will solve the problem.

(a) Find the area of $R$ by integrating with respect to $x$.

(b) Find the area of $R$ by integrating with respect to $y$.

(c) Find the volume of the solid generated by revolving $R$ about the $x$-axis by integrating with respect to $x$.

(d) Find the volume of the solid generated by revolving $R$ about the $x$-axis by integrating with respect to $y$.

(e) Find the volume of the solid generated by revolving $R$ about the $y$-axis by integrating with respect to $x$.

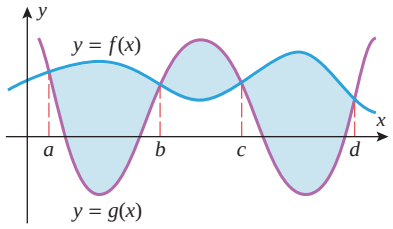
(f) Find the volume of the solid generated by revolving $R$ about the $y$-axis by integrating with respect to $y$.

(g) Find the volume of the solid generated by revolving $R$ about the line $y = -3$ by integrating with respect to $x$.

(h) Find the volume of the solid generated by revolving $R$ about the line $x = 5$ by integrating with respect to $x$.

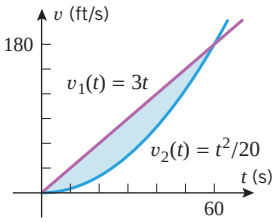
**7.** (a) Set up a sum of definite integrals that represents the total shaded area between the curves $y = f(x)$ and $y = g(x)$ in the accompanying figure on the next page. *(cont.)*

(b) Find the total area enclosed between $y = x^3$ and $y = x$ over the interval $[-1, 2]$.



◀ **Figure Ex-7**

**8.** The accompanying figure shows velocity versus time curves for two cars that move along a straight track, accelerating from rest at a common starting line.
(a) How far apart are the cars after 60 seconds?
(b) How far apart are the cars after $T$ seconds, where $0 \le T \le 60$?



◀ **Figure Ex-8**

**9.** Let $R$ be the region enclosed by the curves $y = x^2 + 4$, $y = x^3$, and the $y$-axis. Find and evaluate a definite integral that represents the volume of the solid generated by revolving $R$ about the $x$-axis.

**10.** A football has the shape of the solid generated by revolving the region bounded between the $x$-axis and the parabola $y = 4R(x^2 - \frac{1}{4}L^2)/L^2$ about the $x$-axis. Find its volume.

**11.** Find the volume of the solid whose base is the region bounded between the curves $y = \sqrt{x}$ and $y = 1/\sqrt{x}$ for $1 \le x \le 4$ and whose cross sections perpendicular to the $x$-axis are squares.

**12.** Consider the region enclosed by $y = \sin^{-1} x$, $y = 0$, and $x = 1$. Set up, but *do not evaluate*, an integral that represents the volume of the solid generated by revolving the region about the $x$-axis using
(a) disks (b) cylindrical shells.

**13.** Find the arc length in the second quadrant of the curve $x^{2/3} + y^{2/3} = 4$ from $x = -8$ to $x = -1$.

**14.** Let $C$ be the curve $y = e^x$ between $x = 0$ and $x = \ln 10$. In each part, set up, but *do not evaluate*, an integral that solves the problem.
(a) Find the arc length of $C$ by integrating with respect to $x$.
(b) Find the arc length of $C$ by integrating with respect to $y$.

**15.** Find the area of the surface generated by revolving the curve $y = \sqrt{25 - x}$, $9 \le x \le 16$, about the $x$-axis.

**16.** Let $C$ be the curve $27x - y^3 = 0$ between $y = 0$ and $y = 2$. In each part, set up, but *do not evaluate*, an integral or a sum of integrals that solves the problem.
(a) Find the area of the surface generated by revolving $C$ about the $x$-axis by integrating with respect to $x$.
(b) Find the area of the surface generated by revolving $C$ about the $y$-axis by integrating with respect to $y$.
(c) Find the area of the surface generated by revolving $C$ about the line $y = -2$ by integrating with respect to $y$.

**17.** Consider the solid generated by revolving the region enclosed by $y = \sec x$, $x = 0$, $x = \pi/3$, and $y = 0$ about the $x$-axis. Find the average value of the area of a cross section of this solid taken perpendicular to the $x$-axis.

**18.** Consider the solid generated by revolving the region enclosed by $y = \sqrt{a^2 - x^2}$ and $y = 0$ about the $x$-axis. Without performing an integration, find the average value of the area of a cross section of this solid taken perpendicular to the $x$-axis.

**19.** (a) A spring exerts a force of 0.5 N when stretched 0.25 m beyond its natural length. Assuming that Hooke's law applies, how much work was performed in stretching the spring to this length?
(b) How far beyond its natural length can the spring be stretched with 25 J of work?

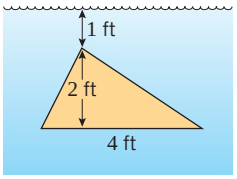
**20.** A boat is anchored so that the anchor is 150 ft below the surface of the water. In the water, the anchor weighs 2000 lb and the chain weighs 30 lb/ft. How much work is required to raise the anchor to the surface?

**21–22** Find the centroid of the region. ■

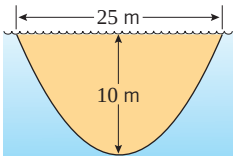
**21.** The region bounded by $y^2 = 4x$ and $y^2 = 8(x - 2)$.

**22.** The upper half of the ellipse $(x/a)^2 + (y/b)^2 = 1$.

**23.** In each part, set up, but *do not evaluate*, an integral that solves the problem.
(a) Find the fluid force exerted on a side of a box that has a 3 m square base and is filled to a depth of 1 m with a liquid of weight density $\rho$ N/m$^3$.
(b) Find the fluid force exerted by a liquid of weight density $\rho$ lb/ft$^3$ on a face of the vertical plate shown in part $(a)$ of the accompanying figure.
(c) Find the fluid force exerted on the parabolic dam in part $(b)$ of the accompanying figure by water that extends to the top of the dam.



$(a)$



$(b)$

▲ **Figure Ex-23**

**24.** Show that for any constant $a$, the function $y = \sinh(ax)$ satisfies the equation $y'' = a^2 y$.

**25.** In each part, prove the identity.
(a) $\cosh 3x = 4\cosh^3 x - 3\cosh x$
(b) $\cosh \frac{1}{2}x = \sqrt{\frac{1}{2}(\cosh x + 1)}$
(c) $\sinh \frac{1}{2}x = \pm\sqrt{\frac{1}{2}(\cosh x - 1)}$

## CHAPTER 6 MAKING CONNECTIONS

**1.** Suppose that $f$ is a nonnegative function defined on $[0, 1]$ such that the area between the graph of $f$ and the interval $[0, 1]$ is $A_1$ and such that the area of the region $R$ between the graph of $g(x) = f(x^2)$ and the interval $[0, 1]$ is $A_2$. In each part, express your answer in terms of $A_1$ and $A_2$.

(a) What is the volume of the solid of revolution generated by revolving $R$ about the $y$-axis?

(b) Find a value of $a$ such that if the $xy$-plane were horizontal, the region $R$ would balance on the line $x = a$.

**2.** A water tank has the shape of a conical frustum with radius of the base 5 ft, radius of the top 10 ft and (vertical) height 15 ft. Suppose the tank is filled with water and consider the problem of finding the work required to pump all the water out through a hole in the top of the tank.

(a) Solve this problem using the method of Example 5 in Section 6.6.

(b) Solve this problem using Definition 6.6.3. [*Hint:* Think of the base as the head of a piston that expands to a watertight fit against the sides of the tank as the piston is pushed upward. What important result about water pressure do you need to use?]

**3.** A disk of radius $a$ is an inhomogeneous lamina whose density is a function $f(r)$ of the distance $r$ to the center of the lamina. Modify the argument used to derive the method of cylindrical shells to find a formula for the mass of the lamina.

**4.** Compare Formula (10) in Section 6.7 with Formula (8) in Section 6.8. Then give a plausible argument that the force on a flat surface immersed vertically in a fluid of constant weight density is equal to the product of the area of the surface and the pressure at the centroid of the surface. Conclude that the force on the surface is the same as if the surface were immersed horizontally at the depth of the centroid.

**5.** ***Archimedes' Principle*** states that a solid immersed in a fluid experiences a buoyant force equal to the weight of the fluid displaced by the solid.

(a) Use the results of Section 6.8 to verify Archimedes' Principle in the case of (i) a box-shaped solid with a pair of faces parallel to the surface of the fluid, (ii) a solid cylinder with vertical axis, and (iii) a cylindrical shell with vertical axis.

(b) Give a plausible argument for Archimedes' Principle in the case of a solid of revolution immersed in fluid such that the axis of revolution of the solid is vertical. [*Hint:* Approximate the solid by a union of cylindrical shells and use the result from part (a).]

# 7 PRINCIPLES OF INTEGRAL EVALUATION

© AP/Wide World Photos

*The floating roof on the Stade de France sports complex is an ellipse. Finding the arc length of an ellipse involves numerical integration techniques introduced in this chapter.*

In earlier chapters we obtained many basic integration formulas as an immediate consequence of the corresponding differentiation formulas. For example, knowing that the derivative of $\sin x$ is $\cos x$ enabled us to deduce that the integral of $\cos x$ is $\sin x$. Subsequently, we expanded our integration repertoire by introducing the method of $u$-substitution. That method enabled us to integrate many functions by transforming the integrand of an unfamiliar integral into a familiar form. However, $u$-substitution alone is not adequate to handle the wide variety of integrals that arise in applications, so additional integration techniques are still needed. In this chapter we will discuss some of those techniques, and we will provide a more systematic procedure for attacking unfamiliar integrals. We will talk more about numerical approximations of definite integrals, and we will explore the idea of integrating over infinite intervals.

## 7.1 AN OVERVIEW OF INTEGRATION METHODS

*In this section we will give a brief overview of methods for evaluating integrals, and we will review the integration formulas that were discussed in earlier sections.*

### METHODS FOR APPROACHING INTEGRATION PROBLEMS

There are three basic approaches for evaluating unfamiliar integrals:

- **Technology**—CAS programs such as *Mathematica*, *Maple*, and the open source program *Sage* are capable of evaluating extremely complicated integrals, and such programs are increasingly available for both computers and handheld calculators.
- **Tables**—Prior to the development of CAS programs, scientists relied heavily on tables to evaluate difficult integrals arising in applications. Such tables were compiled over many years, incorporating the skills and experience of many people. One such table appears in the endpapers of this text, but more comprehensive tables appear in various reference books such as the *CRC Standard Mathematical Tables and Formulae*, CRC Press, Inc., 2002.
- **Transformation Methods**—Transformation methods are methods for converting unfamiliar integrals into familiar integrals. These include $u$-substitution, algebraic manipulation of the integrand, and other methods that we will discuss in this chapter.

None of the three methods is perfect; for example, CAS programs often encounter integrals that they cannot evaluate and they sometimes produce answers that are unnecessarily complicated, tables are not exhaustive and may not include a particular integral of interest, and transformation methods rely on human ingenuity that may prove to be inadequate in difficult problems.

In this chapter we will focus on transformation methods and tables, so it will *not be necessary* to have a CAS such as *Mathematica*, *Maple*, or *Sage*. However, if you have a CAS, then you can use it to confirm the results in the examples, and there are exercises that are designed to be solved with a CAS. If you have a CAS, keep in mind that many of the algorithms that it uses are based on the methods we will discuss here, so an understanding of these methods will help you to use your technology in a more informed way.

## A REVIEW OF FAMILIAR INTEGRATION FORMULAS

The following is a list of basic integrals that we have encountered thus far:

### CONSTANTS, POWERS, EXPONENTIALS

**1.** $\displaystyle\int du = u + C$

**2.** $\displaystyle\int a\,du = a\int du = au + C$

**3.** $\displaystyle\int u^r\,du = \frac{u^{r+1}}{r+1} + C,\ r \neq -1$

**4.** $\displaystyle\int \frac{du}{u} = \ln|u| + C$

**5.** $\displaystyle\int e^u\,du = e^u + C$

**6.** $\displaystyle\int b^u\,du = \frac{b^u}{\ln b} + C,\ b > 0, b \neq 1$

### TRIGONOMETRIC FUNCTIONS

**7.** $\displaystyle\int \sin u\,du = -\cos u + C$

**8.** $\displaystyle\int \cos u\,du = \sin u + C$

**9.** $\displaystyle\int \sec^2 u\,du = \tan u + C$

**10.** $\displaystyle\int \csc^2 u\,du = -\cot u + C$

**11.** $\displaystyle\int \sec u \tan u\,du = \sec u + C$

**12.** $\displaystyle\int \csc u \cot u\,du = -\csc u + C$

**13.** $\displaystyle\int \tan u\,du = -\ln|\cos u| + C$

**14.** $\displaystyle\int \cot u\,du = \ln|\sin u| + C$

### HYPERBOLIC FUNCTIONS

**15.** $\displaystyle\int \sinh u\,du = \cosh u + C$

**16.** $\displaystyle\int \cosh u\,du = \sinh u + C$

**17.** $\displaystyle\int \operatorname{sech}^2 u\,du = \tanh u + C$

**18.** $\displaystyle\int \operatorname{csch}^2 u\,du = -\coth u + C$

**19.** $\displaystyle\int \operatorname{sech} u \tanh u\,du = -\operatorname{sech} u + C$

**20.** $\displaystyle\int \operatorname{csch} u \coth u\,du = -\operatorname{csch} u + C$

### ALGEBRAIC FUNCTIONS ($a > 0$)

**21.** $\displaystyle\int \frac{du}{\sqrt{a^2 - u^2}} = \sin^{-1}\frac{u}{a} + C \qquad (|u| < a)$

**22.** $\displaystyle\int \frac{du}{a^2 + u^2} = \frac{1}{a}\tan^{-1}\frac{u}{a} + C$

**23.** $\displaystyle\int \frac{du}{u\sqrt{u^2 - a^2}} = \frac{1}{a}\sec^{-1}\left|\frac{u}{a}\right| + C \qquad (0 < a < |u|)$

**24.** $\displaystyle\int \frac{du}{\sqrt{a^2+u^2}} = \ln(u+\sqrt{u^2+a^2}) + C$

**25.** $\displaystyle\int \frac{du}{\sqrt{u^2-a^2}} = \ln\left|u+\sqrt{u^2-a^2}\right| + C \qquad (0 < a < |u|)$

**26.** $\displaystyle\int \frac{du}{a^2-u^2} = \frac{1}{2a}\ln\left|\frac{a+u}{a-u}\right| + C$

**27.** $\displaystyle\int \frac{du}{u\sqrt{a^2-u^2}} = -\frac{1}{a}\ln\left|\frac{a+\sqrt{a^2-u^2}}{u}\right| + C \qquad (0 < |u| < a)$

**28.** $\displaystyle\int \frac{du}{u\sqrt{a^2+u^2}} = -\frac{1}{a}\ln\left|\frac{a+\sqrt{a^2+u^2}}{u}\right| + C$

**REMARK** Formula 25 is a generalization of a result in Theorem 6.9.6. Readers who did not cover Section 6.9 can ignore Formulas 24–28 for now, since we will develop other methods for obtaining them in this chapter.

## ✔ QUICK CHECK EXERCISES 7.1 (See page 491 for answers.)

**1.** Use algebraic manipulation and (if necessary) $u$-substitution to integrate the function.

(a) $\displaystyle\int \frac{x+1}{x}\,dx =$ _____

(b) $\displaystyle\int \frac{x+2}{x+1}\,dx =$ _____

(c) $\displaystyle\int \frac{2x+1}{x^2+1}\,dx =$ _____

(d) $\displaystyle\int xe^{3\ln x}\,dx =$ _____

**2.** Use trigonometric identities and (if necessary) $u$-substitution to integrate the function.

(a) $\displaystyle\int \frac{1}{\csc x}\,dx =$ _____

(b) $\displaystyle\int \frac{1}{\cos^2 x}\,dx =$ _____

(c) $\displaystyle\int (\cot^2 x + 1)\,dx =$ _____

(d) $\displaystyle\int \frac{1}{\sec x + \tan x}\,dx =$ _____

**3.** Integrate the function.

(a) $\displaystyle\int \sqrt{x-1}\,dx =$ _____

(b) $\displaystyle\int e^{2x+1}\,dx =$ _____

(c) $\displaystyle\int (\sin^3 x\cos x + \sin x\cos^3 x)\,dx =$ _____

(d) $\displaystyle\int \frac{1}{(e^x+e^{-x})^2}\,dx =$ _____

## EXERCISE SET 7.1

**1–30** Evaluate the integrals by making appropriate $u$-substitutions and applying the formulas reviewed in this section. ■

**1.** $\displaystyle\int (4-2x)^3\,dx$

**2.** $\displaystyle\int 3\sqrt{4+2x}\,dx$

**3.** $\displaystyle\int x\sec^2(x^2)\,dx$

**4.** $\displaystyle\int 4x\tan(x^2)\,dx$

**5.** $\displaystyle\int \frac{\sin 3x}{2+\cos 3x}\,dx$

**6.** $\displaystyle\int \frac{1}{9+4x^2}\,dx$

**7.** $\displaystyle\int e^x \sinh(e^x)\,dx$

**8.** $\displaystyle\int \frac{\sec(\ln x)\tan(\ln x)}{x}\,dx$

**9.** $\displaystyle\int e^{\tan x}\sec^2 x\,dx$

**10.** $\displaystyle\int \frac{x}{\sqrt{1-x^4}}\,dx$

**11.** $\displaystyle\int \cos^5 5x \sin 5x\,dx$

**12.** $\displaystyle\int \frac{\cos x}{\sin x\sqrt{\sin^2 x+1}}\,dx$

**13.** $\displaystyle\int \frac{e^x}{\sqrt{4+e^{2x}}}\,dx$

**14.** $\displaystyle\int \frac{e^{\tan^{-1}x}}{1+x^2}\,dx$

**15.** $\displaystyle\int \frac{e^{\sqrt{x-1}}}{\sqrt{x-1}}\,dx$

**16.** $\displaystyle\int (x+1)\cot(x^2+2x)\,dx$

**17.** $\displaystyle\int \frac{\cosh\sqrt{x}}{\sqrt{x}}\,dx$

**18.** $\displaystyle\int \frac{dx}{x(\ln x)^2}$

**19.** $\displaystyle\int \frac{dx}{\sqrt{x}\,3^{\sqrt{x}}}$

**20.** $\displaystyle\int \sec(\sin\theta)\tan(\sin\theta)\cos\theta\,d\theta$

**21.** $\displaystyle\int \frac{\operatorname{csch}^2(2/x)}{x^2}\,dx$ **22.** $\displaystyle\int \frac{dx}{\sqrt{x^2-4}}$

**23.** $\displaystyle\int \frac{e^{-x}}{4-e^{-2x}}\,dx$ **24.** $\displaystyle\int \frac{\cos(\ln x)}{x}\,dx$

**25.** $\displaystyle\int \frac{e^x}{\sqrt{1-e^{2x}}}\,dx$ **26.** $\displaystyle\int \frac{\sinh(x^{-1/2})}{x^{3/2}}\,dx$

**27.** $\displaystyle\int \frac{x}{\csc(x^2)}\,dx$ **28.** $\displaystyle\int \frac{e^x}{\sqrt{4-e^{2x}}}\,dx$

**29.** $\displaystyle\int x4^{-x^2}\,dx$ **30.** $\displaystyle\int 2^{\pi x}\,dx$

**FOCUS ON CONCEPTS**

**31.** (a) Evaluate the integral $\int \sin x\cos x\,dx$ using the substitution $u=\sin x$.
(b) Evaluate the integral $\int \sin x\cos x\,dx$ using the identity $\sin 2x = 2\sin x\cos x$.
(c) Explain why your answers to parts (a) and (b) are consistent.

**32.** (a) Derive the identity

$$\frac{\operatorname{sech}^2 x}{1+\tanh^2 x} = \operatorname{sech} 2x$$

(b) Use the result in part (a) to evaluate $\int \operatorname{sech} x\,dx$.
(c) Derive the identity

$$\operatorname{sech} x = \frac{2e^x}{e^{2x}+1}$$

(d) Use the result in part (c) to evaluate $\int \operatorname{sech} x\,dx$.
(e) Explain why your answers to parts (b) and (d) are consistent.

**33.** (a) Derive the identity

$$\frac{\sec^2 x}{\tan x} = \frac{1}{\sin x\cos x}$$

(b) Use the identity $\sin 2x = 2\sin x\cos x$ along with the result in part (a) to evaluate $\int \csc x\,dx$.
(c) Use the identity $\cos x = \sin[(\pi/2)-x]$ along with your answer to part (a) to evaluate $\int \sec x\,dx$.

## ✔ QUICK CHECK ANSWERS 7.1

**1.** (a) $x+\ln|x|+C$ (b) $x+\ln|x+1|+C$ (c) $\ln(x^2+1)+\tan^{-1}x+C$ (d) $\dfrac{x^5}{5}+C$ **2.** (a) $-\cos x+C$ (b) $\tan x+C$ (c) $-\cot x+C$ (d) $\ln(1+\sin x)+C$ **3.** (a) $\frac{2}{3}(x-1)^{3/2}+C$ (b) $\frac{1}{2}e^{2x+1}+C$ (c) $\frac{1}{2}\sin^2 x+C$ (d) $\frac{1}{4}\tanh x+C$

# 7.2 INTEGRATION BY PARTS

*In this section we will discuss an integration technique that is essentially an antiderivative formulation of the formula for differentiating a product of two functions.*

## THE PRODUCT RULE AND INTEGRATION BY PARTS

Our primary goal in this section is to develop a general method for attacking integrals of the form

$$\int f(x)g(x)\,dx$$

As a first step, let $G(x)$ be *any* antiderivative of $g(x)$. In this case $G'(x)=g(x)$, so the product rule for differentiating $f(x)G(x)$ can be expressed as

$$\frac{d}{dx}[f(x)G(x)] = f(x)G'(x)+f'(x)G(x) = f(x)g(x)+f'(x)G(x) \tag{1}$$

This implies that $f(x)G(x)$ is an antiderivative of the function on the right side of (1), so we can express (1) in integral form as

$$\int [f(x)g(x)+f'(x)G(x)]\,dx = f(x)G(x)$$

or, equivalently, as

$$\int f(x)g(x)\,dx = f(x)G(x) - \int f'(x)G(x)\,dx \tag{2}$$

This formula allows us to integrate $f(x)g(x)$ by integrating $f'(x)G(x)$ instead, and in many cases the net effect is to replace a difficult integration with an easier one. The application of this formula is called ***integration by parts***.

In practice, we usually rewrite (2) by letting

$$u = f(x), \quad du = f'(x)\,dx$$
$$v = G(x), \quad dv = G'(x)\,dx = g(x)\,dx$$

This yields the following alternative form for (2):

$$\int u\,dv = uv - \int v\,du \tag{3}$$

Note that in Example 1 we omitted the constant of integration in calculating $v$ from $dv$. Had we included a constant of integration, it would have eventually dropped out. This is always the case in integration by parts [Exercise 68(b)], so it is common to omit the constant at this stage of the computation. However, there are certain cases in which making a clever choice of a constant of integration to include with $v$ can simplify the computation of $\int v\,du$ (Exercises 69–71).

► **Example 1** Use integration by parts to evaluate $\int x\cos x\,dx$.

***Solution.*** We will apply Formula (3). The first step is to make a choice for $u$ and $dv$ to put the given integral in the form $\int u\,dv$. We will let

$$u = x \quad \text{and} \quad dv = \cos x\,dx$$

(Other possibilities will be considered later.) The second step is to compute $du$ from $u$ and $v$ from $dv$. This yields

$$du = dx \quad \text{and} \quad v = \int dv = \int \cos x\,dx = \sin x$$

The third step is to apply Formula (3). This yields

$$\int \underbrace{x}_{u}\underbrace{\cos x\,dx}_{dv} = \underbrace{x}_{u}\underbrace{\sin x}_{v} - \int \underbrace{\sin x}_{v}\underbrace{dx}_{du}$$
$$= x\sin x - (-\cos x) + C = x\sin x + \cos x + C \quad ◄$$

## GUIDELINES FOR INTEGRATION BY PARTS

The main goal in integration by parts is to choose $u$ and $dv$ to obtain a new integral that is easier to evaluate than the original. In general, there are no hard and fast rules for doing this; it is mainly a matter of experience that comes from lots of practice. A strategy that often works is to choose $u$ and $dv$ so that $u$ becomes "simpler" when differentiated, while leaving a $dv$ that can be readily integrated to obtain $v$. Thus, for the integral $\int x\cos x\,dx$ in Example 1, both goals were achieved by letting $u = x$ and $dv = \cos x\,dx$. In contrast, $u = \cos x$ would not have been a good first choice in that example, since $du/dx = -\sin x$ is no simpler than $u$. Indeed, had we chosen

$$u = \cos x \qquad dv = x\,dx$$
$$du = -\sin x\,dx \qquad v = \int x\,dx = \frac{x^2}{2}$$

then we would have obtained

$$\int x\cos x\,dx = \frac{x^2}{2}\cos x - \int \frac{x^2}{2}(-\sin x)\,dx = \frac{x^2}{2}\cos x + \frac{1}{2}\int x^2\sin x\,dx$$

For this choice of $u$ and $dv$, the new integral is actually more complicated than the original.

The LIATE method is discussed in the article "A Technique for Integration by Parts," *American Mathematical Monthly*, Vol. 90, 1983, pp. 210–211, by Herbert Kasube.

There is another useful strategy for choosing $u$ and $dv$ that can be applied when the integrand is a product of two functions from *different* categories in the list

**L**ogarithmic, **I**nverse trigonometric, **A**lgebraic, **T**rigonometric, **E**xponential

In this case you will often be successful if you take $u$ to be the function whose category occurs earlier in the list and take $dv$ to be the rest of the integrand. The acronym LIATE will help you to remember the order. The method does not work all the time, but it works often enough to be useful.

Note, for example, that the integrand in Example 1 consists of the product of the *algebraic* function $x$ and the *trigonometric* function $\cos x$. Thus, the LIATE method suggests that we should let $u = x$ and $dv = \cos x\,dx$, which proved to be a successful choice.

**▶ Example 2** Evaluate $\int xe^x\,dx$.

***Solution.*** In this case the integrand is the product of the algebraic function $x$ with the exponential function $e^x$. According to LIATE we should let

$$u = x \quad \text{and} \quad dv = e^x\,dx$$

so that

$$du = dx \quad \text{and} \quad v = \int e^x\,dx = e^x$$

Thus, from (3)

$$\int xe^x\,dx = \int u\,dv = uv - \int v\,du = xe^x - \int e^x\,dx = xe^x - e^x + C \quad \blacktriangleleft$$

**▶ Example 3** Evaluate $\int \ln x\,dx$.

***Solution.*** One choice is to let $u = 1$ and $dv = \ln x\,dx$. But with this choice finding $v$ is equivalent to evaluating $\int \ln x\,dx$ and we have gained nothing. Therefore, the only reasonable choice is to let

$$u = \ln x \qquad dv = dx$$
$$du = \frac{1}{x}\,dx \qquad v = \int dx = x$$

With this choice it follows from (3) that

$$\int \ln x\,dx = \int u\,dv = uv - \int v\,du = x\ln x - \int dx = x\ln x - x + C \quad \blacktriangleleft$$

## REPEATED INTEGRATION BY PARTS

It is sometimes necessary to use integration by parts more than once in the same problem.

**▶ Example 4** Evaluate $\int x^2e^{-x}\,dx$.

***Solution.*** Let

$$u = x^2, \quad dv = e^{-x}\,dx, \quad du = 2x\,dx, \quad v = \int e^{-x}\,dx = -e^{-x}$$

so that from (3)

$$\begin{aligned}\int x^2e^{-x}\,dx &= \int u\,dv = uv - \int v\,du \\ &= x^2(-e^{-x}) - \int -e^{-x}(2x)\,dx \\ &= -x^2e^{-x} + 2\int xe^{-x}\,dx \end{aligned} \tag{4}$$

The last integral is similar to the original except that we have replaced $x^2$ by $x$. Another integration by parts applied to $\int xe^{-x}\,dx$ will complete the problem. We let

$$u = x, \quad dv = e^{-x}\,dx, \quad du = dx, \quad v = \int e^{-x}\,dx = -e^{-x}$$

so that

$$\int xe^{-x}\,dx = x(-e^{-x}) - \int -e^{-x}\,dx = -xe^{-x} + \int e^{-x}\,dx = -xe^{-x} - e^{-x} + C$$

Finally, substituting this into the last line of (4) yields

$$\begin{aligned}\int x^2e^{-x}\,dx &= -x^2e^{-x} + 2\int xe^{-x}\,dx = -x^2e^{-x} + 2(-xe^{-x} - e^{-x}) + C \\ &= -(x^2 + 2x + 2)e^{-x} + C \end{aligned}$$ ◀

The LIATE method suggests that integrals of the form

$$\int e^{ax}\sin bx\,dx \quad \text{and} \quad \int e^{ax}\cos bx\,dx$$

can be evaluated by letting $u = \sin bx$ or $u = \cos bx$ and $dv = e^{ax}\,dx$. However, this will require a technique that deserves special attention.

**▶ Example 5** Evaluate $\int e^x\cos x\,dx$.

***Solution.*** Let

$$u = \cos x, \quad dv = e^x\,dx, \quad du = -\sin x\,dx, \quad v = \int e^x\,dx = e^x$$

Thus,

$$\int e^x\cos x\,dx = \int u\,dv = uv - \int v\,du = e^x\cos x + \int e^x\sin x\,dx \tag{5}$$

Since the integral $\int e^x\sin x\,dx$ is similar in form to the original integral $\int e^x\cos x\,dx$, it seems that nothing has been accomplished. However, let us integrate this new integral by parts. We let

$$u = \sin x, \quad dv = e^x\,dx, \quad du = \cos x\,dx, \quad v = \int e^x\,dx = e^x$$

Thus,

$$\int e^x\sin x\,dx = \int u\,dv = uv - \int v\,du = e^x\sin x - \int e^x\cos x\,dx$$

Together with Equation (5) this yields

$$\int e^x\cos x\,dx = e^x\cos x + e^x\sin x - \int e^x\cos x\,dx \tag{6}$$

which is an equation we can solve for the unknown integral. We obtain

$$2\int e^x \cos x\,dx = e^x \cos x + e^x \sin x$$

and hence

$$\int e^x \cos x\,dx = \tfrac{1}{2}e^x \cos x + \tfrac{1}{2}e^x \sin x + C \quad \blacktriangleleft$$

## A TABULAR METHOD FOR REPEATED INTEGRATION BY PARTS

Integrals of the form

$$\int p(x)\,f(x)\,dx$$

where $p(x)$ is a polynomial, can sometimes be evaluated using repeated integration by parts in which $u$ is taken to be $p(x)$ or one of its derivatives at each stage. Since $du$ is computed by differentiating $u$, the repeated differentiation of $p(x)$ will eventually produce 0, at which point you may be left with a simplified integration problem. A convenient method for organizing the computations into two columns is called ***tabular integration by parts***.

More information on tabular integration by parts can be found in the articles "Tabular Integration by Parts," *College Mathematics Journal*, Vol. 21, 1990, pp. 307–311, by David Horowitz and "More on Tabular Integration by Parts," *College Mathematics Journal*, Vol. 22, 1991, pp. 407–410, by Leonard Gillman.

***Tabular Integration by Parts***

**Step 1.** Differentiate $p(x)$ repeatedly until you obtain 0, and list the results in the first column.

**Step 2.** Integrate $f(x)$ repeatedly and list the results in the second column.

**Step 3.** Draw an arrow from each entry in the first column to the entry that is one row down in the second column.

**Step 4.** Label the arrows with alternating + and − signs, starting with a +.

**Step 5.** For each arrow, form the product of the expressions at its tip and tail and then multiply that product by +1 or −1 in accordance with the sign on the arrow. Add the results to obtain the value of the integral.

This process is illustrated in Figure 7.2.1 for the integral $\int (x^2 - x)\cos x\,dx$.

| REPEATED DIFFERENTIATION | | REPEATED INTEGRATION |
|---|---|---|
| $x^2 - x$ | + | $\cos x$ |
| $2x - 1$ | − | $\sin x$ |
| $2$ | + | $-\cos x$ |
| $0$ | | $-\sin x$ |

$$\int (x^2 - x)\cos x\,dx = (x^2 - x)\sin x + (2x - 1)\cos x - 2\sin x + C$$
$$= (x^2 - x - 2)\sin x + (2x - 1)\cos x + C$$

▶ **Figure 7.2.1**

▶ **Example 6** In Example 11 of Section 5.3 we evaluated $\int x^2\sqrt{x-1}\,dx$ using $u$-substitution. Evaluate this integral using tabular integration by parts.

***Solution.***

| REPEATED DIFFERENTIATION | | REPEATED INTEGRATION |
|---|---|---|
| $x^2$ | + | $(x-1)^{1/2}$ |
| $2x$ | − | $\frac{2}{3}(x-1)^{3/2}$ |
| $2$ | + | $\frac{4}{15}(x-1)^{5/2}$ |
| $0$ | | $\frac{8}{105}(x-1)^{7/2}$ |

The result obtained in Example 6 looks quite different from that obtained in Example 11 of Section 5.3. Show that the two answers are equivalent.

Thus, it follows that

$$\int x^2\sqrt{x-1}\,dx = \tfrac{2}{3}x^2(x-1)^{3/2} - \tfrac{8}{15}x(x-1)^{5/2} + \tfrac{16}{105}(x-1)^{7/2} + C \quad \blacktriangleleft$$

## INTEGRATION BY PARTS FOR DEFINITE INTEGRALS

For definite integrals the formula corresponding to (3) is

$$\int_a^b u\,dv = uv\Big]_a^b - \int_a^b v\,du \tag{7}$$

**REMARK** It is important to keep in mind that the variables $u$ and $v$ in this formula are functions of $x$ and that the limits of integration in (7) are limits on the variable $x$. Sometimes it is helpful to emphasize this by writing (7) as

$$\int_{x=a}^{b} u\,dv = uv\Big]_{x=a}^{b} - \int_{x=a}^{b} v\,du \tag{8}$$

The next example illustrates how integration by parts can be used to integrate the inverse trigonometric functions.

**▶ Example 7** Evaluate $\displaystyle\int_0^1 \tan^{-1}x\,dx$.

***Solution.*** Let

$$u = \tan^{-1}x, \quad dv = dx, \quad du = \frac{1}{1+x^2}\,dx, \quad v = x$$

Thus,

$$\int_0^1 \tan^{-1}x\,dx = \int_0^1 u\,dv = uv\Big]_0^1 - \int_0^1 v\,du$$

The limits of integration refer to $x$; that is, $x = 0$ and $x = 1$.

$$= x\tan^{-1}x\Big]_0^1 - \int_0^1 \frac{x}{1+x^2}\,dx$$

But

$$\int_0^1 \frac{x}{1+x^2}\,dx = \frac{1}{2}\int_0^1 \frac{2x}{1+x^2}\,dx = \frac{1}{2}\ln(1+x^2)\Big]_0^1 = \frac{1}{2}\ln 2$$

so

$$\int_0^1 \tan^{-1}x\,dx = x\tan^{-1}x\Big]_0^1 - \frac{1}{2}\ln 2 = \left(\frac{\pi}{4} - 0\right) - \frac{1}{2}\ln 2 = \frac{\pi}{4} - \ln\sqrt{2} \quad \blacktriangleleft$$

## REDUCTION FORMULAS

Integration by parts can be used to derive ***reduction formulas*** for integrals. These are formulas that express an integral involving a power of a function in terms of an integral that involves a *lower* power of that function. For example, if $n$ is a positive integer and $n \geq 2$, then integration by parts can be used to obtain the reduction formulas

$$\int \sin^n x\,dx = -\frac{1}{n}\sin^{n-1} x\cos x + \frac{n-1}{n}\int \sin^{n-2} x\,dx \tag{9}$$

$$\int \cos^n x\,dx = \frac{1}{n}\cos^{n-1} x\sin x + \frac{n-1}{n}\int \cos^{n-2} x\,dx \tag{10}$$

To illustrate how such formulas can be obtained, let us derive (10). We begin by writing $\cos^n x$ as $\cos^{n-1} x \cdot \cos x$ and letting

$$\begin{aligned} u &= \cos^{n-1} x & dv &= \cos x\,dx \\ du &= (n-1)\cos^{n-2} x(-\sin x)\,dx & v &= \sin x \\ &= -(n-1)\cos^{n-2} x\sin x\,dx \end{aligned}$$

so that

$$\begin{aligned} \int \cos^n x\,dx &= \int \cos^{n-1} x\cos x\,dx = \int u\,dv = uv - \int v\,du \\ &= \cos^{n-1} x\sin x + (n-1)\int \sin^2 x\cos^{n-2} x\,dx \\ &= \cos^{n-1} x\sin x + (n-1)\int (1-\cos^2 x)\cos^{n-2} x\,dx \\ &= \cos^{n-1} x\sin x + (n-1)\int \cos^{n-2} x\,dx - (n-1)\int \cos^n x\,dx \end{aligned}$$

Moving the last term on the right to the left side yields

$$n\int \cos^n x\,dx = \cos^{n-1} x\sin x + (n-1)\int \cos^{n-2} x\,dx$$

from which (10) follows. The derivation of reduction formula (9) is similar (Exercise 63).

Reduction formulas (9) and (10) reduce the exponent of sine (or cosine) by 2. Thus, if the formulas are applied repeatedly, the exponent can eventually be reduced to 0 if $n$ is even or 1 if $n$ is odd, at which point the integration can be completed. We will discuss this method in more detail in the next section, but for now, here is an example that illustrates how reduction formulas work.

**▶ Example 8** Evaluate $\int \cos^4 x\,dx$.

***Solution.*** From (10) with $n = 4$

$$\int \cos^4 x\,dx = \tfrac{1}{4}\cos^3 x\sin x + \tfrac{3}{4}\int \cos^2 x\,dx$$

Now apply (10) with $n = 2$.

$$\begin{aligned} &= \tfrac{1}{4}\cos^3 x\sin x + \tfrac{3}{4}\left(\tfrac{1}{2}\cos x\sin x + \tfrac{1}{2}\int dx\right) \\ &= \tfrac{1}{4}\cos^3 x\sin x + \tfrac{3}{8}\cos x\sin x + \tfrac{3}{8}x + C \quad \blacktriangleleft \end{aligned}$$

## ✔ QUICK CHECK EXERCISES 7.2 (See page 500 for answers.)

**1.** (a) If $G'(x) = g(x)$, then

$$\int f(x)g(x)\,dx = f(x)G(x) - _____$$

(b) If $u = f(x)$ and $v = G(x)$, then the formula in part (a) can be written in the form $\int u\,dv =$ _____.

**2.** Find an appropriate choice of $u$ and $dv$ for integration by parts of each integral. Do not evaluate the integral.

(a) $\int x \ln x\,dx$; $u =$ _____, $dv =$ _____

(b) $\int (x-2)\sin x\,dx$; $u =$ _____, $dv =$ _____

(c) $\int \sin^{-1} x\,dx$; $u =$ _____, $dv =$ _____

(d) $\int \dfrac{x}{\sqrt{x-1}}dx$; $u =$ _____, $dv =$ _____

**3.** Use integration by parts to evaluate the integral.

(a) $\int xe^{2x}\,dx$ (b) $\int \ln(x-1)\,dx$

(c) $\int_0^{\pi/6} x\sin 3x\,dx$

**4.** Use a reduction formula to evaluate $\int \sin^3 x\,dx$.

## EXERCISE SET 7.2

**1–38** Evaluate the integral. ■

**1.** $\int xe^{-2x}\,dx$ **2.** $\int xe^{3x}\,dx$

**3.** $\int x^2e^x\,dx$ **4.** $\int x^2e^{-2x}\,dx$

**33.** $\int_2^4 \sec^{-1}\sqrt{\theta}\,d\theta$ **34.** $\int_1^2 x\sec^{-1} x\,dx$

**35.** $\int_0^{\pi} x\sin 2x\,dx$ **36.** $\int_0^{\pi} (x + x\cos x)\,dx$

**37.** $\int_1^3 \sqrt{x}\tan^{-1}\sqrt{x}\,dx$ **38.** $\int_0^2 \ln(x^2+1)\,dx$

**39–42 True–False** Determine whether the statement is true or false. Explain your answer. ■

**39.** The main goal in integration by parts is to choose $u$ and $dv$ to obtain a new integral that is easier to evaluate than the original.

**40.** Applying the LIATE strategy to evaluate $\int x^3\ln x\,dx$, we should choose $u = x^3$ and $dv = \ln x\,dx$.

**41.** To evaluate $\int \ln e^x\,dx$ using integration by parts, choose $dv = e^x\,dx$.

**42.** Tabular integration by parts is useful for integrals of the form $\int p(x)f(x)\,dx$, where $p(x)$ is a polynomial and $f(x)$ can be repeatedly integrated.

**43–44** Evaluate the integral by making a $u$-substitution and then integrating by parts. ■

**43.** $\int e^{\sqrt{x}}\,dx$ **44.** $\int \cos\sqrt{x}\,dx$

**45.** Prove that tabular integration by parts gives the correct answer for

$$\int p(x)f(x)\,dx$$

where $p(x)$ is any *quadratic polynomial* and $f(x)$ is any function that can be repeatedly integrated.

**46.** The computations of any integral evaluated by repeated integration by parts can be organized using tabular integration by parts. Use this organization to evaluate $\int e^x\cos x\,dx$ in

two ways: first by repeated differentiation of $\cos x$ (compare Example 5), and then by repeated differentiation of $e^x$.

**47–52** Evaluate the integral using tabular integration by parts.

**47.** $\int (3x^2 - x + 2)e^{-x}\,dx$

**48.** $\int (x^2 + x + 1)\sin x\,dx$

**49.** $\int 4x^4 \sin 2x\,dx$

**50.** $\int x^3\sqrt{2x+1}\,dx$

**51.** $\int e^{ax}\sin bx\,dx$

**52.** $\int e^{-3\theta}\sin 5\theta\,d\theta$

**53.** Consider the integral $\int \sin x \cos x\,dx$.
(a) Evaluate the integral two ways: first using integration by parts, and then using the substitution $u = \sin x$.
(b) Show that the results of part (a) are equivalent.
(c) Which of the two methods do you prefer? Discuss the reasons for your preference.

**54.** Evaluate the integral

$$\int_0^1 \frac{x^3}{\sqrt{x^2+1}}\,dx$$

using
(a) integration by parts
(b) the substitution $u = \sqrt{x^2+1}$.

**55.** (a) Find the area of the region enclosed by $y = \ln x$, the line $x = e$, and the $x$-axis.
(b) Find the volume of the solid generated when the region in part (a) is revolved about the $x$-axis.

**56.** Find the area of the region between $y = x\sin x$ and $y = x$ for $0 \le x \le \pi/2$.

**57.** Find the volume of the solid generated when the region between $y = \sin x$ and $y = 0$ for $0 \le x \le \pi$ is revolved about the $y$-axis.

**58.** Find the volume of the solid generated when the region enclosed between $y = \cos x$ and $y = 0$ for $0 \le x \le \pi/2$ is revolved about the $y$-axis.

**59.** A particle moving along the $x$-axis has velocity function $v(t) = t^3 \sin t$. How far does the particle travel from time $t = 0$ to $t = \pi$?

**60.** The study of sawtooth waves in electrical engineering leads to integrals of the form

$$\int_{-\pi/\omega}^{\pi/\omega} t\sin(k\omega t)\,dt$$

where $k$ is an integer and $\omega$ is a nonzero constant. Evaluate the integral.

**61.** Use reduction formula (9) to evaluate
(a) $\int \sin^4 x\,dx$ (b) $\int_0^{\pi/2} \sin^5 x\,dx$.

**62.** Use reduction formula (10) to evaluate
(a) $\int \cos^5 x\,dx$ (b) $\int_0^{\pi/2} \cos^6 x\,dx$.

**63.** Derive reduction formula (9).

**64.** In each part, use integration by parts or other methods to derive the reduction formula.

(a) $$\int \sec^n x\,dx = \frac{\sec^{n-2} x\tan x}{n-1} + \frac{n-2}{n-1}\int \sec^{n-2} x\,dx$$

(b) $$\int \tan^n x\,dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x\,dx$$

(c) $$\int x^n e^x\,dx = x^n e^x - n\int x^{n-1}e^x\,dx$$

**65–66** Use the reduction formulas in Exercise 64 to evaluate the integrals.

**65.** (a) $\int \tan^4 x\,dx$ (b) $\int \sec^4 x\,dx$ (c) $\int x^3 e^x\,dx$

**66.** (a) $\int x^2 e^{3x}\,dx$ (b) $\int_0^1 xe^{-\sqrt{x}}\,dx$

[*Hint:* First make a substitution.]

**67.** Let $f$ be a function whose second derivative is continuous on $[-1, 1]$. Show that

$$\int_{-1}^{1} xf''(x)\,dx = f'(1) + f'(-1) - f(1) + f(-1)$$

## FOCUS ON CONCEPTS

**68.** (a) In the integral $\int x\cos x\,dx$, let

$$u = x, \quad dv = \cos x\,dx,$$
$$du = dx, \quad v = \sin x + C_1$$

Show that the constant $C_1$ cancels out, thus giving the same solution obtained by omitting $C_1$.
(b) Show that in general

$$uv - \int v\,du = u(v + C_1) - \int (v + C_1)\,du$$

thereby justifying the omission of the constant of integration when calculating $v$ in integration by parts.

**69.** Evaluate $\int \ln(x+1)\,dx$ using integration by parts. Simplify the computation of $\int v\,du$ by introducing a constant of integration $C_1 = 1$ when going from $dv$ to $v$.

**70.** Evaluate $\int \ln(3x-2)\,dx$ using integration by parts. Simplify the computation of $\int v\,du$ by introducing a constant of integration $C_1 = -\frac{2}{3}$ when going from $dv$ to $v$. Compare your solution with your answer to Exercise 13.

**71.** Evaluate $\int x\tan^{-1} x\,dx$ using integration by parts. Simplify the computation of $\int v\,du$ by introducing a constant of integration $C_1 = \frac{1}{2}$ when going from $dv$ to $v$.

**72.** What equation results if integration by parts is applied to the integral

$$\int \frac{1}{x\ln x}\,dx$$

with the choices

$$u = \frac{1}{\ln x} \quad \text{and} \quad dv = \frac{1}{x}\,dx?$$

In what sense is this equation true? In what sense is it false?

**73.** **Writing** Explain how the product rule for derivatives and the technique of integration by parts are related.

**74.** **Writing** For what sort of problems are the integration techniques of substitution and integration by parts "competing" techniques? Describe situations, with examples, where each of these techniques would be preferred over the other.

## 7.3 INTEGRATING TRIGONOMETRIC FUNCTIONS

*In the last section we derived reduction formulas for integrating positive integer powers of sine, cosine, tangent, and secant. In this section we will show how to work with those reduction formulas, and we will discuss methods for integrating other kinds of integrals that involve trigonometric functions.*

### INTEGRATING POWERS OF SINE AND COSINE

We begin by recalling two reduction formulas from the preceding section.

$$\int \sin^n x\,dx = -\frac{1}{n}\sin^{n-1}x\cos x + \frac{n-1}{n}\int \sin^{n-2}x\,dx \tag{1}$$

$$\int \cos^n x\,dx = \frac{1}{n}\cos^{n-1}x\sin x + \frac{n-1}{n}\int \cos^{n-2}x\,dx \tag{2}$$

In the case where $n = 2$, these formulas yield

$$\int \sin^2 x\,dx = -\tfrac{1}{2}\sin x\cos x + \tfrac{1}{2}\int dx = \tfrac{1}{2}x - \tfrac{1}{2}\sin x\cos x + C \tag{3}$$

$$\int \cos^2 x\,dx = \tfrac{1}{2}\cos x\sin x + \tfrac{1}{2}\int dx = \tfrac{1}{2}x + \tfrac{1}{2}\sin x\cos x + C \tag{4}$$

Alternative forms of these integration formulas can be derived from the trigonometric identities

$$\sin^2 x = \tfrac{1}{2}(1-\cos 2x) \quad \text{and} \quad \cos^2 x = \tfrac{1}{2}(1+\cos 2x) \tag{5–6}$$

which follow from the double-angle formulas

$$\cos 2x = 1 - 2\sin^2 x \quad \text{and} \quad \cos 2x = 2\cos^2 x - 1$$

These identities yield

$$\int \sin^2 x\,dx = \tfrac{1}{2}\int (1-\cos 2x)\,dx = \tfrac{1}{2}x - \tfrac{1}{4}\sin 2x + C \tag{7}$$

$$\int \cos^2 x\,dx = \tfrac{1}{2}\int (1+\cos 2x)\,dx = \tfrac{1}{2}x + \tfrac{1}{4}\sin 2x + C \tag{8}$$

Observe that the antiderivatives in Formulas (3) and (4) involve both sines and cosines, whereas those in (7) and (8) involve sines alone. However, the apparent discrepancy is easy to resolve by using the identity

$$\sin 2x = 2 \sin x \cos x$$

to rewrite (7) and (8) in forms (3) and (4), or conversely.

In the case where $n = 3$, the reduction formulas for integrating $\sin^3 x$ and $\cos^3 x$ yield

$$\int \sin^3 x\, dx = -\tfrac{1}{3} \sin^2 x \cos x + \tfrac{2}{3} \int \sin x\, dx = -\tfrac{1}{3} \sin^2 x \cos x - \tfrac{2}{3} \cos x + C \qquad (9)$$

$$\int \cos^3 x\, dx = \tfrac{1}{3} \cos^2 x \sin x + \tfrac{2}{3} \int \cos x\, dx = \tfrac{1}{3} \cos^2 x \sin x + \tfrac{2}{3} \sin x + C \qquad (10)$$

If desired, Formula (9) can be expressed in terms of cosines alone by using the identity $\sin^2 x = 1 - \cos^2 x$, and Formula (10) can be expressed in terms of sines alone by using the identity $\cos^2 x = 1 - \sin^2 x$. We leave it for you to do this and confirm that

$$\int \sin^3 x\, dx = \tfrac{1}{3} \cos^3 x - \cos x + C \qquad (11)$$

$$\int \cos^3 x\, dx = \sin x - \tfrac{1}{3} \sin^3 x + C \qquad (12)$$

**TECHNOLOGY MASTERY**

The *Maple* CAS produces forms (11) and (12) when asked to integrate $\sin^3 x$ and $\cos^3 x$, but *Mathematica* produces

$$\int \sin^3 x\, dx = -\tfrac{3}{4} \cos x + \tfrac{1}{12} \cos 3x + C$$

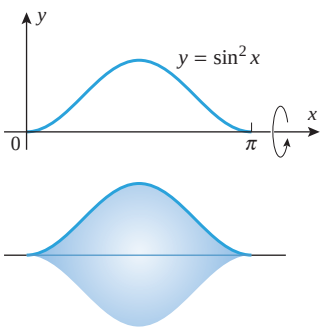
$$\int \cos^3 x\, dx = \tfrac{3}{4} \sin x + \tfrac{1}{12} \sin 3x + C$$

Use trigonometric identities to reconcile the results of the two programs.

We leave it as an exercise to obtain the following formulas by first applying the reduction formulas, and then using appropriate trigonometric identities.

$$\int \sin^4 x\, dx = \tfrac{3}{8}x - \tfrac{1}{4} \sin 2x + \tfrac{1}{32} \sin 4x + C \qquad (13)$$

$$\int \cos^4 x\, dx = \tfrac{3}{8}x + \tfrac{1}{4} \sin 2x + \tfrac{1}{32} \sin 4x + C \qquad (14)$$



▲ Figure 7.3.1

**▶ Example 1** Find the volume $V$ of the solid that is obtained when the region under the curve $y = \sin^2 x$ over the interval $[0, \pi]$ is revolved about the $x$-axis (Figure 7.3.1).

***Solution.*** Using the method of disks, Formula (5) of Section 6.2, and Formula (13) above yields

$$V = \int_0^{\pi} \pi \sin^4 x\, dx = \pi \left[\tfrac{3}{8}x - \tfrac{1}{4} \sin 2x + \tfrac{1}{32} \sin 4x\right]_0^{\pi} = \tfrac{3}{8}\pi^2 \quad \blacktriangleleft$$

## INTEGRATING PRODUCTS OF SINES AND COSINES

If $m$ and $n$ are positive integers, then the integral

$$\int \sin^m x \cos^n x\, dx$$

can be evaluated by one of the three procedures stated in Table 7.3.1, depending on whether $m$ and $n$ are odd or even.

**▶ Example 2** Evaluate

(a) $\displaystyle\int \sin^4 x \cos^5 x\, dx$ (b) $\displaystyle\int \sin^4 x \cos^4 x\, dx$

**Table 7.3.1**
INTEGRATING PRODUCTS OF SINES AND COSINES

| $\int \sin^m x \cos^n x\, dx$ | PROCEDURE | RELEVANT IDENTITIES |
|---|---|---|
| $n$ odd | • Split off a factor of $\cos x$.<br>• Apply the relevant identity.<br>• Make the substitution $u = \sin x$. | $\cos^2 x = 1 - \sin^2 x$ |
| $m$ odd | • Split off a factor of $\sin x$.<br>• Apply the relevant identity.<br>• Make the substitution $u = \cos x$. | $\sin^2 x = 1 - \cos^2 x$ |
| $\begin{cases} m \text{ even} \\ n \text{ even} \end{cases}$ | • Use the relevant identities to reduce the powers on $\sin x$ and $\cos x$. | $\begin{cases} \sin^2 x = \frac{1}{2}(1 - \cos 2x) \\ \cos^2 x = \frac{1}{2}(1 + \cos 2x) \end{cases}$ |

***Solution (a).*** Since $n = 5$ is odd, we will follow the first procedure in Table 7.3.1:

$$\begin{aligned}
\int \sin^4 x \cos^5 x\, dx &= \int \sin^4 x \cos^4 x \cos x\, dx \\
&= \int \sin^4 x (1 - \sin^2 x)^2 \cos x\, dx \\
&= \int u^4 (1 - u^2)^2\, du \\
&= \int (u^4 - 2u^6 + u^8)\, du \\
&= \tfrac{1}{5}u^5 - \tfrac{2}{7}u^7 + \tfrac{1}{9}u^9 + C \\
&= \tfrac{1}{5}\sin^5 x - \tfrac{2}{7}\sin^7 x + \tfrac{1}{9}\sin^9 x + C
\end{aligned}$$

***Solution (b).*** Since $m = n = 4$, both exponents are even, so we will follow the third procedure in Table 7.3.1:

$$\begin{aligned}
\int \sin^4 x \cos^4 x\, dx &= \int (\sin^2 x)^2 (\cos^2 x)^2\, dx \\
&= \int \left(\tfrac{1}{2}[1 - \cos 2x]\right)^2 \left(\tfrac{1}{2}[1 + \cos 2x]\right)^2\, dx \\
&= \tfrac{1}{16}\int (1 - \cos^2 2x)^2\, dx \\
&= \tfrac{1}{16}\int \sin^4 2x\, dx \qquad \text{Note that this can be obtained more directly from the original integral using the identity } \sin x \cos x = \tfrac{1}{2}\sin 2x. \\
&= \tfrac{1}{32}\int \sin^4 u\, du \qquad u = 2x,\ du = 2\,dx \text{ or } dx = \tfrac{1}{2}\,du \\
&= \tfrac{1}{32}\left(\tfrac{3}{8}u - \tfrac{1}{4}\sin 2u + \tfrac{1}{32}\sin 4u\right) + C \qquad \text{Formula (13)} \\
&= \tfrac{3}{128}x - \tfrac{1}{128}\sin 4x + \tfrac{1}{1024}\sin 8x + C \quad \blacktriangleleft
\end{aligned}$$

Integrals of the form

$$\int \sin mx \cos nx\, dx, \quad \int \sin mx \sin nx\, dx, \quad \int \cos mx \cos nx\, dx \tag{15}$$

can be found by using the trigonometric identities

$$\sin\alpha \cos\beta = \tfrac{1}{2}[\sin(\alpha-\beta) + \sin(\alpha+\beta)] \tag{16}$$

$$\sin\alpha \sin\beta = \tfrac{1}{2}[\cos(\alpha-\beta) - \cos(\alpha+\beta)] \tag{17}$$

$$\cos\alpha \cos\beta = \tfrac{1}{2}[\cos(\alpha-\beta) + \cos(\alpha+\beta)] \tag{18}$$

to express the integrand as a sum or difference of sines and cosines.

**▶ Example 3** Evaluate $\int \sin 7x \cos 3x\, dx$.

***Solution.*** Using (16) yields

$$\int \sin 7x \cos 3x\, dx = \tfrac{1}{2}\int (\sin 4x + \sin 10x)\, dx = -\tfrac{1}{8}\cos 4x - \tfrac{1}{20}\cos 10x + C \quad \blacktriangleleft$$

## INTEGRATING POWERS OF TANGENT AND SECANT

The procedures for integrating powers of tangent and secant closely parallel those for sine and cosine. The idea is to use the following reduction formulas (which were derived in Exercise 64 of Section 7.2) to reduce the exponent in the integrand until the resulting integral can be evaluated:

$$\int \tan^n x\, dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x\, dx \tag{19}$$

$$\int \sec^n x\, dx = \frac{\sec^{n-2} x \tan x}{n-1} + \frac{n-2}{n-1}\int \sec^{n-2} x\, dx \tag{20}$$

In the case where $n$ is odd, the exponent can be reduced to 1, leaving us with the problem of integrating $\tan x$ or $\sec x$. These integrals are given by

$$\int \tan x\, dx = \ln|\sec x| + C \tag{21}$$

$$\int \sec x\, dx = \ln|\sec x + \tan x| + C \tag{22}$$

Formula (21) can be obtained by writing

$$\int \tan x\, dx = \int \frac{\sin x}{\cos x}\, dx$$

$$= -\ln|\cos x| + C \qquad \boxed{\begin{array}{l} u = \cos x \\ du = -\sin x\, dx \end{array}}$$

$$= \ln|\sec x| + C \qquad \boxed{\ln|\cos x| = -\ln\frac{1}{|\cos x|}}$$

To obtain Formula (22) we write

$$\int \sec x\, dx = \int \sec x \left(\frac{\sec x + \tan x}{\sec x + \tan x}\right) dx = \int \frac{\sec^2 x + \sec x \tan x}{\sec x + \tan x}\, dx$$

$$= \ln|\sec x + \tan x| + C \qquad \boxed{\begin{array}{l} u = \sec x + \tan x \\ du = (\sec^2 x + \sec x \tan x)\, dx \end{array}}$$

The following basic integrals occur frequently and are worth noting:

$$\int \tan^2 x\,dx = \tan x - x + C \tag{23}$$

$$\int \sec^2 x\,dx = \tan x + C \tag{24}$$

Formula (24) is already known to us, since the derivative of $\tan x$ is $\sec^2 x$. Formula (23) can be obtained by applying reduction formula (19) with $n = 2$ (verify) or, alternatively, by using the identity

$$1 + \tan^2 x = \sec^2 x$$

to write

$$\int \tan^2 x\,dx = \int (\sec^2 x - 1)\,dx = \tan x - x + C$$

The formulas

$$\int \tan^3 x\,dx = \tfrac{1}{2}\tan^2 x - \ln|\sec x| + C \tag{25}$$

$$\int \sec^3 x\,dx = \tfrac{1}{2}\sec x \tan x + \tfrac{1}{2}\ln|\sec x + \tan x| + C \tag{26}$$

can be deduced from (21), (22), and reduction formulas (19) and (20) as follows:

$$\int \tan^3 x\,dx = \tfrac{1}{2}\tan^2 x - \int \tan x\,dx = \tfrac{1}{2}\tan^2 x - \ln|\sec x| + C$$

$$\int \sec^3 x\,dx = \tfrac{1}{2}\sec x \tan x + \tfrac{1}{2}\int \sec x\,dx = \tfrac{1}{2}\sec x \tan x + \tfrac{1}{2}\ln|\sec x + \tan x| + C$$

## INTEGRATING PRODUCTS OF TANGENTS AND SECANTS

If $m$ and $n$ are positive integers, then the integral

$$\int \tan^m x \sec^n x\,dx$$

can be evaluated by one of the three procedures stated in Table 7.3.2, depending on whether $m$ and $n$ are odd or even.

**Table 7.3.2**

INTEGRATING PRODUCTS OF TANGENTS AND SECANTS

| $\int \tan^m x \sec^n x\,dx$ | PROCEDURE | RELEVANT IDENTITIES |
|---|---|---|
| $n$ even | • Split off a factor of $\sec^2 x$.<br>• Apply the relevant identity.<br>• Make the substitution $u = \tan x$. | $\sec^2 x = \tan^2 x + 1$ |
| $m$ odd | • Split off a factor of $\sec x \tan x$.<br>• Apply the relevant identity.<br>• Make the substitution $u = \sec x$. | $\tan^2 x = \sec^2 x - 1$ |
| $\begin{cases} m \text{ even} \\ n \text{ odd} \end{cases}$ | • Use the relevant identities to reduce the integrand to powers of $\sec x$ alone.<br>• Then use the reduction formula for powers of $\sec x$. | $\tan^2 x = \sec^2 x - 1$ |

▶ **Example 4** Evaluate

$$\text{(a)} \int \tan^2 x \sec^4 x\,dx \qquad \text{(b)} \int \tan^3 x \sec^3 x\,dx \qquad \text{(c)} \int \tan^2 x \sec x\,dx$$

***Solution (a).*** Since $n = 4$ is even, we will follow the first procedure in Table 7.3.2:

$$\begin{aligned}\int \tan^2 x \sec^4 x\,dx &= \int \tan^2 x \sec^2 x \sec^2 x\,dx \\ &= \int \tan^2 x(\tan^2 x + 1)\sec^2 x\,dx \\ &= \int u^2(u^2+1)\,du \\ &= \tfrac{1}{5}u^5 + \tfrac{1}{3}u^3 + C = \tfrac{1}{5}\tan^5 x + \tfrac{1}{3}\tan^3 x + C\end{aligned}$$

***Solution (b).*** Since $m = 3$ is odd, we will follow the second procedure in Table 7.3.2:

$$\begin{aligned}\int \tan^3 x \sec^3 x\,dx &= \int \tan^2 x \sec^2 x(\sec x \tan x)\,dx \\ &= \int (\sec^2 x - 1)\sec^2 x(\sec x \tan x)\,dx \\ &= \int (u^2 - 1)u^2\,du \\ &= \tfrac{1}{5}u^5 - \tfrac{1}{3}u^3 + C = \tfrac{1}{5}\sec^5 x - \tfrac{1}{3}\sec^3 x + C\end{aligned}$$

***Solution (c).*** Since $m = 2$ is even and $n = 1$ is odd, we will follow the third procedure in Table 7.3.2:

$$\begin{aligned}\int \tan^2 x \sec x\,dx &= \int (\sec^2 x - 1)\sec x\,dx \\ &= \int \sec^3 x\,dx - \int \sec x\,dx \qquad \boxed{\text{See (26) and (22)}} \\ &= \tfrac{1}{2}\sec x \tan x + \tfrac{1}{2}\ln|\sec x + \tan x| - \ln|\sec x + \tan x| + C \\ &= \tfrac{1}{2}\sec x \tan x - \tfrac{1}{2}\ln|\sec x + \tan x| + C \quad ◀\end{aligned}$$

## AN ALTERNATIVE METHOD FOR INTEGRATING POWERS OF SINE, COSINE, TANGENT, AND SECANT

The methods in Tables 7.3.1 and 7.3.2 can sometimes be applied if $m = 0$ or $n = 0$ to integrate positive integer powers of sine, cosine, tangent, and secant without reduction formulas. For example, instead of using the reduction formula to integrate $\sin^3 x$, we can apply the second procedure in Table 7.3.1:

$$\begin{aligned}\int \sin^3 x\,dx &= \int (\sin^2 x)\sin x\,dx \\ &= \int (1 - \cos^2 x)\sin x\,dx \qquad \boxed{\begin{array}{l}u = \cos x \\ du = -\sin x\,dx\end{array}} \\ &= -\int (1 - u^2)\,du \\ &= \tfrac{1}{3}u^3 - u + C = \tfrac{1}{3}\cos^3 x - \cos x + C\end{aligned}$$

which agrees with (11).

With the aid of the identity

$$1 + \cot^2 x = \csc^2 x$$

the techniques in Table 7.3.2 can be adapted to evaluate integrals of the form

$$\int \cot^m x \csc^n x\,dx$$

It is also possible to derive reduction formulas for powers of cot and csc that are analogous to Formulas (19) and (20).

▲ **Figure 7.3.2** A flight path with constant compass heading from New York City to Moscow follows a spiral toward the North Pole but is a straight line segment on a Mercator projection.

## MERCATOR'S MAP OF THE WORLD

The integral of sec $x$ plays an important role in the design of navigational maps for charting nautical and aeronautical courses. Sailors and pilots usually chart their courses along paths with constant compass headings; for example, the course might be 30° northeast or 135° southeast. Except for courses that are parallel to the equator or run due north or south, a course with constant compass heading spirals around the Earth toward one of the poles (as in the top part of Figure 7.3.2). In 1569 the Flemish mathematician and geographer Gerhard Kramer (1512–1594) (better known by the Latin name Mercator) devised a world map, called the *Mercator projection*, in which spirals of constant compass headings appear as straight lines. This was extremely important because it enabled sailors to determine compass headings between two points by connecting them with a straight line on a map (as in the bottom part of Figure 7.3.2).

If the Earth is assumed to be a sphere of radius 4000 mi, then the lines of latitude at 1° increments are equally spaced about 70 mi apart (why?). However, in the Mercator projection, the lines of latitude become wider apart toward the poles, so that two widely spaced latitude lines near the poles may be actually the same distance apart on the Earth as two closely spaced latitude lines near the equator. It can be proved that on a Mercator map in which the equatorial line has length $L$, the vertical distance $D_\beta$ on the map between the equator (latitude 0°) and the line of latitude $\beta°$ is

$$D_\beta = \frac{L}{2\pi}\int_0^{\beta\pi/180} \sec x\,dx \tag{27}$$

## ✔ QUICK CHECK EXERCISES 7.3 (See page 508 for answers.)

**1.** Complete each trigonometric identity with an expression involving $\cos 2x$.

(a) $\sin^2 x =$ _____ (b) $\cos^2 x =$ _____

(c) $\cos^2 x - \sin^2 x =$ _____

**2.** Evaluate the integral.

(a) $\displaystyle\int \sec^2 x\,dx =$ _____

(b) $\displaystyle\int \tan^2 x\,dx =$ _____

(c) $\displaystyle\int \sec x\,dx =$ _____

(d) $\displaystyle\int \tan x\,dx =$ _____

**3.** Use the indicated substitution to rewrite the integral in terms of $u$. Do not evaluate the integral.

(a) $\displaystyle\int \sin^2 x\cos x\,dx;\ u = \sin x$

(b) $\displaystyle\int \sin^3 x\cos^2 x\,dx;\ u = \cos x$

(c) $\displaystyle\int \tan^3 x\sec^2 x\,dx;\ u = \tan x$

(d) $\displaystyle\int \tan^3 x\sec x\,dx;\ u = \sec x$

## EXERCISE SET 7.3

**1–52** Evaluate the integral. ■

**1.** $\displaystyle\int \cos^3 x\sin x\,dx$

**2.** $\displaystyle\int \sin^5 3x\cos 3x\,dx$

**3.** $\displaystyle\int \sin^2 5\theta\,d\theta$

**4.** $\displaystyle\int \cos^2 3x\,dx$

**5.** $\displaystyle\int \sin^3 a\theta\,d\theta$

**6.** $\displaystyle\int \cos^3 at\,dt$

**7.** $\displaystyle\int \sin ax\cos ax\,dx$

**8.** $\displaystyle\int \sin^3 x\cos^3 x\,dx$

**9.** $\displaystyle\int \sin^2 t\cos^3 t\,dt$

**10.** $\displaystyle\int \sin^3 x\cos^2 x\,dx$

**11.** $\int \sin^2 x \cos^2 x \, dx$

**12.** $\int \sin^2 x \cos^4 x \, dx$

**13.** $\int \sin 2x \cos 3x \, dx$

**14.** $\int \sin 3\theta \cos 2\theta \, d\theta$

**15.** $\int \sin x \cos(x/2) \, dx$

**16.** $\int \cos^{1/3} x \sin x \, dx$

**17.** $\int_0^{\pi/2} \cos^3 x \, dx$

**18.** $\int_0^{\pi/2} \sin^2 \frac{x}{2} \cos^2 \frac{x}{2} \, dx$

**19.** $\int_0^{\pi/3} \sin^4 3x \cos^3 3x \, dx$

**20.** $\int_{-\pi}^{\pi} \cos^2 5\theta \, d\theta$

**21.** $\int_0^{\pi/6} \sin 4x \cos 2x \, dx$

**22.** $\int_0^{2\pi} \sin^2 kx \, dx$

**23.** $\int \sec^2(2x - 1) \, dx$

**24.** $\int \tan 5x \, dx$

**25.** $\int e^{-x} \tan(e^{-x}) \, dx$

**26.** $\int \cot 3x \, dx$

**27.** $\int \sec 4x \, dx$

**28.** $\int \frac{\sec(\sqrt{x})}{\sqrt{x}} \, dx$

**29.** $\int \tan^2 x \sec^2 x \, dx$

**30.** $\int \tan^5 x \sec^4 x \, dx$

**31.** $\int \tan 4x \sec^4 4x \, dx$

**32.** $\int \tan^4 \theta \sec^4 \theta \, d\theta$

**33.** $\int \sec^5 x \tan^3 x \, dx$

**34.** $\int \tan^5 \theta \sec \theta \, d\theta$

**35.** $\int \tan^4 x \sec x \, dx$

**36.** $\int \tan^2 x \sec^3 x \, dx$

**37.** $\int \tan t \sec^3 t \, dt$

**38.** $\int \tan x \sec^5 x \, dx$

**39.** $\int \sec^4 x \, dx$

**40.** $\int \sec^5 x \, dx$

**41.** $\int \tan^3 4x \, dx$

**42.** $\int \tan^4 x \, dx$

**43.** $\int \sqrt{\tan x} \sec^4 x \, dx$

**44.** $\int \tan x \sec^{3/2} x \, dx$

**45.** $\int_0^{\pi/8} \tan^2 2x \, dx$

**46.** $\int_0^{\pi/6} \sec^3 2\theta \tan 2\theta \, d\theta$

**47.** $\int_0^{\pi/2} \tan^5 \frac{x}{2} \, dx$

**48.** $\int_0^{1/4} \sec \pi x \tan \pi x \, dx$

**49.** $\int \cot^3 x \csc^3 x \, dx$

**50.** $\int \cot^2 3t \sec 3t \, dt$

**51.** $\int \cot^3 x \, dx$

**52.** $\int \csc^4 x \, dx$

**53–56 True–False** Determine whether the statement is true or false. Explain your answer.

**53.** To evaluate $\int \sin^5 x \cos^8 x \, dx$, use the trigonometric identity $\sin^2 x = 1 - \cos^2 x$ and the substitution $u = \cos x$.

**54.** To evaluate $\int \sin^8 x \cos^5 x \, dx$, use the trigonometric identity $\sin^2 x = 1 - \cos^2 x$ and the substitution $u = \cos x$.

**55.** The trigonometric identity

$$\sin\alpha \cos\beta = \tfrac{1}{2}[\sin(\alpha - \beta) + \sin(\alpha + \beta)]$$

is often useful for evaluating integrals of the form $\int \sin^m x \cos^n x \, dx$.

**56.** The integral $\int \tan^4 x \sec^5 x \, dx$ is equivalent to one whose integrand is a polynomial in $\sec x$.

**57.** Let $m$, $n$ be distinct nonnegative integers. Use Formulas (16)–(18) to prove:

(a) $\int_0^{2\pi} \sin mx \cos nx \, dx = 0$

(b) $\int_0^{2\pi} \cos mx \cos nx \, dx = 0$

(c) $\int_0^{2\pi} \sin mx \sin nx \, dx = 0.$

**58.** Evaluate the integrals in Exercise 57 when $m$ and $n$ denote the *same* nonnegative integer.

**59.** Find the arc length of the curve $y = \ln(\cos x)$ over the interval $[0, \pi/4]$.

**60.** Find the volume of the solid generated when the region enclosed by $y = \tan x$, $y = 1$, and $x = 0$ is revolved about the $x$-axis.

**61.** Find the volume of the solid that results when the region enclosed by $y = \cos x$, $y = \sin x$, $x = 0$, and $x = \pi/4$ is revolved about the $x$-axis.

**62.** The region bounded below by the $x$-axis and above by the portion of $y = \sin x$ from $x = 0$ to $x = \pi$ is revolved about the $x$-axis. Find the volume of the resulting solid.

**63.** Use Formula (27) to show that if the length of the equatorial line on a Mercator projection is $L$, then the vertical distance $D$ between the latitude lines at $\alpha°$ and $\beta°$ on the same side of the equator (where $\alpha < \beta$) is

$$D = \frac{L}{2\pi} \ln \left| \frac{\sec \beta° + \tan \beta°}{\sec \alpha° + \tan \alpha°} \right|$$

**64.** Suppose that the equator has a length of 100 cm on a Mercator projection. In each part, use the result in Exercise 63 to answer the question.

(a) What is the vertical distance on the map between the equator and the line at 25° north latitude?

(b) What is the vertical distance on the map between New Orleans, Louisiana, at 30° north latitude and Winnipeg, Canada, at 50° north latitude?

**FOCUS ON CONCEPTS**

**65.** (a) Show that

$$\int \csc x \, dx = -\ln|\csc x + \cot x| + C$$

(b) Show that the result in part (a) can also be written as

$$\int \csc x \, dx = \ln|\csc x - \cot x| + C$$

and

$$\int \csc x \, dx = \ln\left|\tan \tfrac{1}{2}x\right| + C$$

**66.** Rewrite $\sin x + \cos x$ in the form

$$A\sin(x+\phi)$$

and use your result together with Exercise 65 to evaluate

$$\int \frac{dx}{\sin x + \cos x}$$

**67.** Use the method of Exercise 66 to evaluate

$$\int \frac{dx}{a\sin x + b\cos x} \quad (a, b \text{ not both zero})$$

**68.** (a) Use Formula (9) in Section 7.2 to show that

$$\int_0^{\pi/2} \sin^n x\,dx = \frac{n-1}{n}\int_0^{\pi/2} \sin^{n-2} x\,dx \quad (n \geq 2)$$

(b) Use this result to derive the ***Wallis sine formulas***:

$$\int_0^{\pi/2} \sin^n x\,dx = \frac{\pi}{2}\cdot\frac{1\cdot 3\cdot 5\cdots(n-1)}{2\cdot 4\cdot 6\cdots n} \quad \begin{pmatrix} n \text{ even} \\ \text{and} \geq 2 \end{pmatrix}$$

$$\int_0^{\pi/2} \sin^n x\,dx = \frac{2\cdot 4\cdot 6\cdots(n-1)}{3\cdot 5\cdot 7\cdots n} \quad \begin{pmatrix} n \text{ odd} \\ \text{and} \geq 3 \end{pmatrix}$$

**69.** Use the Wallis formulas in Exercise 68 to evaluate

(a) $\displaystyle\int_0^{\pi/2} \sin^3 x\,dx$ (b) $\displaystyle\int_0^{\pi/2} \sin^4 x\,dx$

(c) $\displaystyle\int_0^{\pi/2} \sin^5 x\,dx$ (d) $\displaystyle\int_0^{\pi/2} \sin^6 x\,dx$.

**70.** Use Formula (10) in Section 7.2 and the method of Exercise 68 to derive the ***Wallis cosine formulas***:

$$\int_0^{\pi/2} \cos^n x\,dx = \frac{\pi}{2}\cdot\frac{1\cdot 3\cdot 5\cdots(n-1)}{2\cdot 4\cdot 6\cdots n} \quad \begin{pmatrix} n \text{ even} \\ \text{and} \geq 2 \end{pmatrix}$$

$$\int_0^{\pi/2} \cos^n x\,dx = \frac{2\cdot 4\cdot 6\cdots(n-1)}{3\cdot 5\cdot 7\cdots n} \quad \begin{pmatrix} n \text{ odd} \\ \text{and} \geq 3 \end{pmatrix}$$

# 7.4 TRIGONOMETRIC SUBSTITUTIONS

*In this section we will discuss a method for evaluating integrals containing radicals by making substitutions involving trigonometric functions. We will also show how integrals containing quadratic polynomials can sometimes be evaluated by completing the square.*

## THE METHOD OF TRIGONOMETRIC SUBSTITUTION

To start, we will be concerned with integrals that contain expressions of the form

$$\sqrt{a^2-x^2}, \quad \sqrt{x^2+a^2}, \quad \sqrt{x^2-a^2}$$

in which $a$ is a positive constant. The basic idea for evaluating such integrals is to make a substitution for $x$ that will eliminate the radical. For example, to eliminate the radical in the expression $\sqrt{a^2-x^2}$, we can make the substitution

$$x = a\sin\theta, \quad -\pi/2 \leq \theta \leq \pi/2 \tag{1}$$

which yields

$$\sqrt{a^2-x^2} = \sqrt{a^2-a^2\sin^2\theta} = \sqrt{a^2(1-\sin^2\theta)}$$
$$= a\sqrt{\cos^2\theta} = a|\cos\theta| = a\cos\theta \qquad \cos\theta \geq 0 \text{ since } -\pi/2 \leq \theta \leq \pi/2$$

The restriction on $\theta$ in (1) serves two purposes—it enables us to replace $|\cos\theta|$ by $\cos\theta$ to simplify the calculations, and it also ensures that the substitutions can be rewritten as $\theta = \sin^{-1}(x/a)$, if needed.

**▶ Example 1** Evaluate $\displaystyle\int \frac{dx}{x^2\sqrt{4-x^2}}$.

***Solution.*** To eliminate the radical we make the substitution

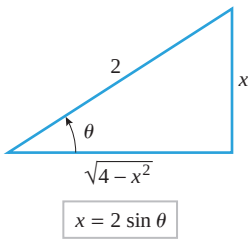
$$x = 2\sin\theta, \quad dx = 2\cos\theta\, d\theta$$

This yields

$$\int \frac{dx}{x^2\sqrt{4-x^2}} = \int \frac{2\cos\theta\, d\theta}{(2\sin\theta)^2\sqrt{4-4\sin^2\theta}}$$

$$= \int \frac{2\cos\theta\, d\theta}{(2\sin\theta)^2(2\cos\theta)} = \frac{1}{4}\int \frac{d\theta}{\sin^2\theta}$$

$$= \frac{1}{4}\int \csc^2\theta\, d\theta = -\frac{1}{4}\cot\theta + C \tag{2}$$



▲ **Figure 7.4.1**

At this point we have completed the integration; however, because the original integral was expressed in terms of $x$, it is desirable to express $\cot\theta$ in terms of $x$ as well. This can be done using trigonometric identities, but the expression can also be obtained by writing the substitution $x = 2\sin\theta$ as $\sin\theta = x/2$ and representing it geometrically as in Figure 7.4.1. From that figure we obtain

$$\cot\theta = \frac{\sqrt{4-x^2}}{x}$$

Substituting this in (2) yields

$$\int \frac{dx}{x^2\sqrt{4-x^2}} = -\frac{1}{4}\frac{\sqrt{4-x^2}}{x} + C \quad \blacktriangleleft$$

**▶ Example 2** Evaluate $\displaystyle\int_1^{\sqrt{2}} \frac{dx}{x^2\sqrt{4-x^2}}$.

***Solution.*** There are two possible approaches: we can make the substitution in the indefinite integral (as in Example 1) and then evaluate the definite integral using the $x$-limits of integration, or we can make the substitution in the definite integral and convert the $x$-limits to the corresponding $\theta$-limits.

**Method 1.**

Using the result from Example 1 with the $x$-limits of integration yields

$$\int_1^{\sqrt{2}} \frac{dx}{x^2\sqrt{4-x^2}} = -\frac{1}{4}\left[\frac{\sqrt{4-x^2}}{x}\right]_1^{\sqrt{2}} = -\frac{1}{4}\left[1-\sqrt{3}\right] = \frac{\sqrt{3}-1}{4}$$

**Method 2.**

The substitution $x = 2\sin\theta$ can be expressed as $x/2 = \sin\theta$ or $\theta = \sin^{-1}(x/2)$, so the $\theta$-limits that correspond to $x = 1$ and $x = \sqrt{2}$ are

$$x = 1: \quad \theta = \sin^{-1}(1/2) = \pi/6$$

$$x = \sqrt{2}: \quad \theta = \sin^{-1}(\sqrt{2}/2) = \pi/4$$

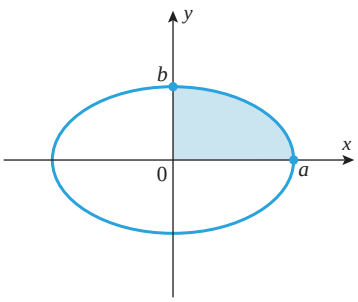
Thus, from (2) in Example 1 we obtain

$$\int_1^{\sqrt{2}} \frac{dx}{x^2\sqrt{4-x^2}} = \frac{1}{4}\int_{\pi/6}^{\pi/4} \csc^2\theta\, d\theta \qquad \text{Convert } x\text{-limits to } \theta\text{-limits.}$$

$$= -\frac{1}{4}\left[\cot\theta\right]_{\pi/6}^{\pi/4} = -\frac{1}{4}\left[1-\sqrt{3}\right] = \frac{\sqrt{3}-1}{4} \quad \blacktriangleleft$$

**▶ Example 3** Find the area of the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$



$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

▲ Figure 7.4.2

***Solution.*** Because the ellipse is symmetric about both axes, its area $A$ is four times the area in the first quadrant (Figure 7.4.2). If we solve the equation of the ellipse for $y$ in terms of $x$, we obtain

$$y = \pm\frac{b}{a}\sqrt{a^2-x^2}$$

where the positive square root gives the equation of the upper half. Thus, the area $A$ is given by

$$A = 4\int_0^a \frac{b}{a}\sqrt{a^2-x^2}\,dx = \frac{4b}{a}\int_0^a \sqrt{a^2-x^2}\,dx$$

To evaluate this integral, we will make the substitution $x = a\sin\theta$ (so $dx = a\cos\theta\, d\theta$) and convert the $x$-limits of integration to $\theta$-limits. Since the substitution can be expressed as $\theta = \sin^{-1}(x/a)$, the $\theta$-limits of integration are

$$x = 0: \quad \theta = \sin^{-1}(0) = 0$$
$$x = a: \quad \theta = \sin^{-1}(1) = \pi/2$$

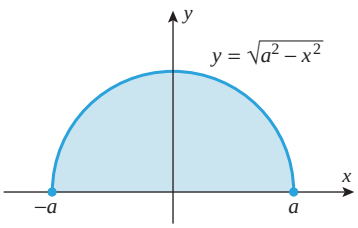
Thus, we obtain

$$A = \frac{4b}{a}\int_0^a \sqrt{a^2-x^2}\,dx = \frac{4b}{a}\int_0^{\pi/2} \sqrt{a^2-a^2\sin^2\theta}\cdot a\cos\theta\, d\theta$$

$$= \frac{4b}{a}\int_0^{\pi/2} a\cos\theta\cdot a\cos\theta\, d\theta$$

$$= 4ab\int_0^{\pi/2} \cos^2\theta\, d\theta = 4ab\int_0^{\pi/2} \frac{1}{2}(1+\cos 2\theta)\, d\theta$$

$$= 2ab\left[\theta + \frac{1}{2}\sin 2\theta\right]_0^{\pi/2} = 2ab\left[\frac{\pi}{2} - 0\right] = \pi ab \quad \blacktriangleleft$$



▲ Figure 7.4.3

**REMARK**

In the special case where $a = b$, the ellipse becomes a circle of radius $a$, and the area formula becomes $A = \pi a^2$, as expected. It is worth noting that

$$\int_{-a}^{a} \sqrt{a^2-x^2}\,dx = \tfrac{1}{2}\pi a^2 \tag{3}$$

since this integral represents the area of the upper semicircle (Figure 7.4.3).

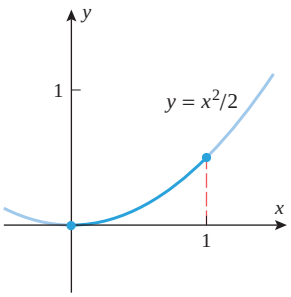
**TECHNOLOGY MASTERY**

If you have a calculating utility with a numerical integration capability, use it and Formula (3) to approximate $\pi$ to three decimal places.

Thus far, we have focused on using the substitution $x = a\sin\theta$ to evaluate integrals involving radicals of the form $\sqrt{a^2-x^2}$. Table 7.4.1 summarizes this method and describes some other substitutions of this type.

**Table 7.4.1**
TRIGONOMETRIC SUBSTITUTIONS

| EXPRESSION IN THE INTEGRAND | SUBSTITUTION | RESTRICTION ON $\theta$ | SIMPLIFICATION |
|---|---|---|---|
| $\sqrt{a^2 - x^2}$ | $x = a \sin\theta$ | $-\pi/2 \le \theta \le \pi/2$ | $a^2 - x^2 = a^2 - a^2\sin^2\theta = a^2\cos^2\theta$ |
| $\sqrt{a^2 + x^2}$ | $x = a \tan\theta$ | $-\pi/2 < \theta < \pi/2$ | $a^2 + x^2 = a^2 + a^2\tan^2\theta = a^2\sec^2\theta$ |
| $\sqrt{x^2 - a^2}$ | $x = a \sec\theta$ | $\begin{cases} 0 \le \theta < \pi/2 & (\text{if } x \ge a) \\ \pi/2 < \theta \le \pi & (\text{if } x \le -a) \end{cases}$ | $x^2 - a^2 = a^2\sec^2\theta - a^2 = a^2\tan^2\theta$ |



▲ **Figure 7.4.4**

▶ **Example 4** Find the arc length of the curve $y = x^2/2$ from $x = 0$ to $x = 1$ (Figure 7.4.4).

***Solution.*** From Formula (4) of Section 6.4 the arc length $L$ of the curve is

$$L = \int_0^1 \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx = \int_0^1 \sqrt{1 + x^2}\, dx$$

The integrand involves a radical of the form $\sqrt{a^2 + x^2}$ with $a = 1$, so from Table 7.4.1 we make the substitution

$$x = \tan\theta, \quad -\pi/2 < \theta < \pi/2$$
$$\frac{dx}{d\theta} = \sec^2\theta \quad \text{or} \quad dx = \sec^2\theta\, d\theta$$

Since this substitution can be expressed as $\theta = \tan^{-1} x$, the $\theta$-limits of integration that correspond to the $x$-limits, $x = 0$ and $x = 1$, are

$$x = 0: \quad \theta = \tan^{-1} 0 = 0$$
$$x = 1: \quad \theta = \tan^{-1} 1 = \pi/4$$

Thus,

$$\begin{aligned} L = \int_0^1 \sqrt{1 + x^2}\, dx &= \int_0^{\pi/4} \sqrt{1 + \tan^2\theta}\, \sec^2\theta\, d\theta \\ &= \int_0^{\pi/4} \sqrt{\sec^2\theta}\, \sec^2\theta\, d\theta \qquad 1 + \tan^2\theta = \sec^2\theta \\ &= \int_0^{\pi/4} |\sec\theta| \sec^2\theta\, d\theta \\ &= \int_0^{\pi/4} \sec^3\theta\, d\theta \qquad \sec\theta > 0 \text{ since } -\pi/2 < \theta < \pi/2 \\ &= \left[\tfrac{1}{2}\sec\theta\tan\theta + \tfrac{1}{2}\ln|\sec\theta + \tan\theta|\right]_0^{\pi/4} \qquad \text{Formula (26) of Section 7.3} \\ &= \tfrac{1}{2}\left[\sqrt{2} + \ln(\sqrt{2} + 1)\right] \approx 1.148 \quad \blacktriangleleft \end{aligned}$$

▶ **Example 5** Evaluate $\displaystyle\int \frac{\sqrt{x^2 - 25}}{x}\, dx$, assuming that $x \ge 5$.

***Solution.*** The integrand involves a radical of the form $\sqrt{x^2 - a^2}$ with $a = 5$, so from Table 7.4.1 we make the substitution

$$x = 5\sec\theta, \quad 0 \le \theta < \pi/2$$

$$\frac{dx}{d\theta} = 5\sec\theta\tan\theta \quad \text{or} \quad dx = 5\sec\theta\tan\theta\, d\theta$$

Thus,

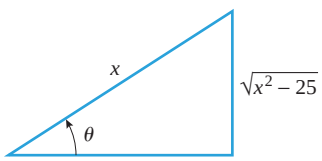
$$\begin{aligned}\int \frac{\sqrt{x^2-25}}{x}\,dx &= \int \frac{\sqrt{25\sec^2\theta - 25}}{5\sec\theta}(5\sec\theta\tan\theta)\,d\theta \\ &= \int \frac{5|\tan\theta|}{5\sec\theta}(5\sec\theta\tan\theta)\,d\theta \\ &= 5\int \tan^2\theta\,d\theta \qquad \boxed{\tan\theta \ge 0 \text{ since } 0 \le \theta < \pi/2} \\ &= 5\int(\sec^2\theta - 1)\,d\theta = 5\tan\theta - 5\theta + C\end{aligned}$$

To express the solution in terms of $x$, we will represent the substitution $x = 5\sec\theta$ geometrically by the triangle in Figure 7.4.5, from which we obtain

$$\tan\theta = \frac{\sqrt{x^2-25}}{5}$$

From this and the fact that the substitution can be expressed as $\theta = \sec^{-1}(x/5)$, we obtain

$$\int \frac{\sqrt{x^2-25}}{x}\,dx = \sqrt{x^2-25} - 5\sec^{-1}\left(\frac{x}{5}\right) + C \quad \blacktriangleleft$$



▲ **Figure 7.4.5**

## INTEGRALS INVOLVING $ax^2 + bx + c$

Integrals that involve a quadratic expression $ax^2 + bx + c$, where $a \ne 0$ and $b \ne 0$, can often be evaluated by first completing the square, then making an appropriate substitution. The following example illustrates this idea.

**Example 6** Evaluate $\displaystyle\int \frac{x}{x^2 - 4x + 8}\,dx$.

***Solution.*** Completing the square yields

$$x^2 - 4x + 8 = (x^2 - 4x + 4) + 8 - 4 = (x-2)^2 + 4$$

Thus, the substitution

$$u = x - 2, \quad du = dx$$

yields

$$\begin{aligned}\int \frac{x}{x^2-4x+8}\,dx &= \int \frac{x}{(x-2)^2+4}\,dx = \int \frac{u+2}{u^2+4}\,du \\ &= \int \frac{u}{u^2+4}\,du + 2\int \frac{du}{u^2+4} \\ &= \frac{1}{2}\int \frac{2u}{u^2+4}\,du + 2\int \frac{du}{u^2+4} \\ &= \frac{1}{2}\ln(u^2+4) + 2\left(\frac{1}{2}\right)\tan^{-1}\frac{u}{2} + C \\ &= \frac{1}{2}\ln[(x-2)^2+4] + \tan^{-1}\left(\frac{x-2}{2}\right) + C \quad \blacktriangleleft\end{aligned}$$

## ✔ QUICK CHECK EXERCISES 7.4 (See page 514 for answers.)

1. For each expression, give a trigonometric substitution that will eliminate the radical.
   (a) $\sqrt{a^2 - x^2}$ _____ (b) $\sqrt{a^2 + x^2}$ _____
   (c) $\sqrt{x^2 - a^2}$ _____
2. If $x = 2\sec\theta$ and $0 < \theta < \pi/2$, then
   (a) $\sin\theta =$ _____ (b) $\cos\theta =$ _____
   (c) $\tan\theta =$ _____.
3. In each part, state the trigonometric substitution that you would try first to evaluate the integral. Do not evaluate the integral.
   (a) $\displaystyle\int \sqrt{9 + x^2}\,dx$ _____
   (b) $\displaystyle\int \sqrt{9 - x^2}\,dx$ _____
   (c) $\displaystyle\int \sqrt{1 - 9x^2}\,dx$ _____

26. $\displaystyle\int_0^3 \frac{x^3}{(3 + x^2)^{5/2}}\,dx$

**27–30 True–False** Determine whether the statement is true or false. Explain your answer. ■

27. An integrand involving a radical of the form $\sqrt{a^2 - x^2}$ suggests the substitution $x = a\sin\theta$.
28. The trigonometric substitution $x = a\sin\theta$ is made with the restriction $0 \le \theta \le \pi$.
29. An integrand involving a radical of the form $\sqrt{x^2 - a^2}$ suggests the substitution $x = a\cos\theta$.
30. The area enclosed by the ellipse $x^2 + 4y^2 = 1$ is $\pi/2$.

**FOCUS ON CONCEPTS**

31. The integral
$$\int \frac{x}{x^2 + 4}\,dx$$
can be evaluated either by a trigonometric substitution or by the substitution $u = x^2 + 4$. Do it both ways and show that the results are equivalent.
32. The integral
$$\int \frac{x^2}{x^2 + 4}\,dx$$
can be evaluated either by a trigonometric substitution or by algebraically rewriting the numerator of the integrand as $(x^2 + 4) - 4$. Do it both ways and show that the results are equivalent.
33. Find the arc length of the curve $y = \ln x$ from $x = 1$ to $x = 2$.
34. Find the arc length of the curve $y = x^2$ from $x = 0$ to $x = 1$.

**35.** Find the area of the surface generated when the curve in Exercise 34 is revolved about the $x$-axis.

**36.** Find the volume of the solid generated when the region enclosed by $x = y(1 - y^2)^{1/4}$, $y = 0$, $y = 1$, and $x = 0$ is revolved about the $y$-axis.

**37–48** Evaluate the integral. ■

**37.** $\displaystyle\int \frac{dx}{x^2 - 4x + 5}$

**38.** $\displaystyle\int \frac{dx}{\sqrt{2x - x^2}}$

**39.** $\displaystyle\int \frac{dx}{\sqrt{3 + 2x - x^2}}$

**40.** $\displaystyle\int \frac{dx}{16x^2 + 16x + 5}$

**41.** $\displaystyle\int \frac{dx}{\sqrt{x^2 - 6x + 10}}$

**42.** $\displaystyle\int \frac{x}{x^2 + 2x + 2}\,dx$

**43.** $\displaystyle\int \sqrt{3 - 2x - x^2}\,dx$

**44.** $\displaystyle\int \frac{e^x}{\sqrt{1 + e^x + e^{2x}}}\,dx$

**45.** $\displaystyle\int \frac{dx}{2x^2 + 4x + 7}$

**46.** $\displaystyle\int \frac{2x + 3}{4x^2 + 4x + 5}\,dx$

**47.** $\displaystyle\int_1^2 \frac{dx}{\sqrt{4x - x^2}}$

**48.** $\displaystyle\int_0^4 \sqrt{x(4 - x)}\,dx$

C **49–50** There is a good chance that your CAS will not be able to evaluate these integrals as stated. If this is so, make a substitution that converts the integral into one that your CAS can evaluate. ■

**49.** $\displaystyle\int \cos x \sin x \sqrt{1 - \sin^4 x}\,dx$

**50.** $\displaystyle\int (x \cos x + \sin x)\sqrt{1 + x^2 \sin^2 x}\,dx$

**51.** (a) Use the ***hyperbolic substitution*** $x = 3 \sinh u$, the identity $\cosh^2 u - \sinh^2 u = 1$, and Theorem 6.9.4 to evaluate

$$\int \frac{dx}{\sqrt{x^2 + 9}}$$

(b) Evaluate the integral in part (a) using a trigonometric substitution and show that the result agrees with that obtained in part (a).

**52.** Use the hyperbolic substitutionn $x = \cosh u$, the identity $\sinh^2 u = \frac{1}{2}(\cosh 2u - 1)$, and the results referenced in Exercise 51 to evaluate

$$\int \sqrt{x^2 - 1}\,dx, \quad x \geq 1$$

**53.** **Writing** The trigonometric substitution $x = a \sin\theta$, $-\pi/2 \leq \theta \leq \pi/2$, is suggested for an integral whose integrand involves $\sqrt{a^2 - x^2}$. Discuss the implications of restricting $\theta$ to $\pi/2 \leq \theta \leq 3\pi/2$, and explain why the restriction $-\pi/2 \leq \theta \leq \pi/2$ should be preferred.

**54.** **Writing** The trigonometric substitution $x = a \cos\theta$ could also be used for an integral whose integrand involves $\sqrt{a^2 - x^2}$. Determine an appropriate restriction for $\theta$ with the substitution $x = a \cos\theta$, and discuss how to apply this substitution in appropriate integrals. Illustrate your discussion by evaluating the integral in Example 1 using a substitution of this type.

## 7.5 INTEGRATING RATIONAL FUNCTIONS BY PARTIAL FRACTIONS

*Recall that a rational function is a ratio of two polynomials. In this section we will give a general method for integrating rational functions that is based on the idea of decomposing a rational function into a sum of simple rational functions that can be integrated by the methods studied in earlier sections.*

### ■ PARTIAL FRACTIONS

In algebra, one learns to combine two or more fractions into a single fraction by finding a common denominator. For example,

$$\frac{2}{x - 4} + \frac{3}{x + 1} = \frac{2(x + 1) + 3(x - 4)}{(x - 4)(x + 1)} = \frac{5x - 10}{x^2 - 3x - 4} \tag{1}$$

However, for purposes of integration, the left side of (1) is preferable to the right side since each of the terms is easy to integrate:

$$\int \frac{5x-10}{x^2-3x-4}\,dx = \int \frac{2}{x-4}\,dx + \int \frac{3}{x+1}\,dx = 2\ln|x-4| + 3\ln|x+1| + C$$

Thus, it is desirable to have some method that will enable us to obtain the left side of (1), starting with the right side. To illustrate how this can be done, we begin by noting that on the left side the numerators are constants and the denominators are the factors of the denominator on the right side. Thus, to find the left side of (1), starting from the right side, we could factor the denominator of the right side and look for constants $A$ and $B$ such that

$$\frac{5x-10}{(x-4)(x+1)} = \frac{A}{x-4} + \frac{B}{x+1} \tag{2}$$

One way to find the constants $A$ and $B$ is to multiply (2) through by $(x-4)(x+1)$ to clear fractions. This yields

$$5x - 10 = A(x+1) + B(x-4) \tag{3}$$

This relationship holds for all $x$, so it holds in particular if $x = 4$ or $x = -1$. Substituting $x = 4$ in (3) makes the second term on the right drop out and yields the equation $10 = 5A$ or $A = 2$; and substituting $x = -1$ in (3) makes the first term on the right drop out and yields the equation $-15 = -5B$ or $B = 3$. Substituting these values in (2) we obtain

$$\frac{5x-10}{(x-4)(x+1)} = \frac{2}{x-4} + \frac{3}{x+1} \tag{4}$$

which agrees with (1).

A second method for finding the constants $A$ and $B$ is to multiply out the right side of (3) and collect like powers of $x$ to obtain

$$5x - 10 = (A+B)x + (A-4B)$$

Since the polynomials on the two sides are identical, their corresponding coefficients must be the same. Equating the corresponding coefficients on the two sides yields the following system of equations in the unknowns $A$ and $B$:

$$\begin{aligned} A + B &= 5 \\ A - 4B &= -10 \end{aligned}$$

Solving this system yields $A = 2$ and $B = 3$ as before (verify).

The terms on the right side of (4) are called ***partial fractions*** of the expression on the left side because they each constitute *part* of that expression. To find those partial fractions we first had to make a guess about their form, and then we had to find the unknown constants. Our next objective is to extend this idea to general rational functions. For this purpose, suppose that $P(x)/Q(x)$ is a ***proper rational function***, by which we mean that the degree of the numerator is less than the degree of the denominator. There is a theorem in advanced algebra which states that every proper rational function can be expressed as a sum

$$\frac{P(x)}{Q(x)} = F_1(x) + F_2(x) + \cdots + F_n(x)$$

where $F_1(x), F_2(x), \ldots, F_n(x)$ are rational functions of the form

$$\frac{A}{(ax+b)^k} \quad \text{or} \quad \frac{Ax+B}{(ax^2+bx+c)^k}$$

in which the denominators are factors of $Q(x)$. The sum is called the ***partial fraction decomposition*** of $P(x)/Q(x)$, and the terms are called ***partial fractions***. As in our opening example, there are two parts to finding a partial fraction decomposition: determining the exact form of the decomposition and finding the unknown constants.

## FINDING THE FORM OF A PARTIAL FRACTION DECOMPOSITION

The first step in finding the form of the partial fraction decomposition of a proper rational function $P(x)/Q(x)$ is to factor $Q(x)$ completely into linear and irreducible quadratic factors, and then collect all repeated factors so that $Q(x)$ is expressed as a product of *distinct* factors of the form

$$(ax+b)^m \quad \text{and} \quad (ax^2+bx+c)^m$$

From these factors we can determine the form of the partial fraction decomposition using two rules that we will now discuss.

## LINEAR FACTORS

If all of the factors of $Q(x)$ are linear, then the partial fraction decomposition of $P(x)/Q(x)$ can be determined by using the following rule:

**LINEAR FACTOR RULE** For each factor of the form $(ax+b)^m$, the partial fraction decomposition contains the following sum of $m$ partial fractions:

$$\frac{A_1}{ax+b}+\frac{A_2}{(ax+b)^2}+\cdots+\frac{A_m}{(ax+b)^m}$$

where $A_1, A_2, \ldots, A_m$ are constants to be determined. In the case where $m=1$, only the first term in the sum appears.

**Example 1** Evaluate $\displaystyle\int \frac{dx}{x^2+x-2}$.

***Solution.*** The integrand is a proper rational function that can be written as

$$\frac{1}{x^2+x-2}=\frac{1}{(x-1)(x+2)}$$

The factors $x-1$ and $x+2$ are both linear and appear to the first power, so each contributes one term to the partial fraction decomposition by the linear factor rule. Thus, the decomposition has the form

$$\frac{1}{(x-1)(x+2)}=\frac{A}{x-1}+\frac{B}{x+2} \tag{5}$$

where $A$ and $B$ are constants to be determined. Multiplying this expression through by $(x-1)(x+2)$ yields

$$1=A(x+2)+B(x-1) \tag{6}$$

As discussed earlier, there are two methods for finding $A$ and $B$: we can substitute values of $x$ that are chosen to make terms on the right drop out, or we can multiply out on the right and equate corresponding coefficients on the two sides to obtain a system of equations that can be solved for $A$ and $B$. We will use the first approach.

Setting $x=1$ makes the second term in (6) drop out and yields $1=3A$ or $A=\frac{1}{3}$; and setting $x=-2$ makes the first term in (6) drop out and yields $1=-3B$ or $B=-\frac{1}{3}$. Substituting these values in (5) yields the partial fraction decomposition

$$\frac{1}{(x-1)(x+2)}=\frac{\frac{1}{3}}{x-1}+\frac{-\frac{1}{3}}{x+2}$$

The integration can now be completed as follows:

$$\int \frac{dx}{(x-1)(x+2)} = \frac{1}{3}\int \frac{dx}{x-1} - \frac{1}{3}\int \frac{dx}{x+2}$$
$$= \frac{1}{3}\ln|x-1| - \frac{1}{3}\ln|x+2| + C = \frac{1}{3}\ln\left|\frac{x-1}{x+2}\right| + C \quad \blacktriangleleft$$

If the factors of $Q(x)$ are linear and none are repeated, as in the last example, then the recommended method for finding the constants in the partial fraction decomposition is to substitute appropriate values of $x$ to make terms drop out. However, if some of the linear factors are repeated, then it will not be possible to find all of the constants in this way. In this case the recommended procedure is to find as many constants as possible by substitution and then find the rest by equating coefficients. This is illustrated in the next example.

**▶ Example 2** Evaluate $\displaystyle\int \frac{2x+4}{x^3-2x^2}\,dx$.

***Solution.*** The integrand can be rewritten as

$$\frac{2x+4}{x^3-2x^2} = \frac{2x+4}{x^2(x-2)}$$

Although $x^2$ is a quadratic factor, it is *not* irreducible since $x^2 = xx$. Thus, by the linear factor rule, $x^2$ introduces two terms (since $m = 2$) of the form

$$\frac{A}{x} + \frac{B}{x^2}$$

and the factor $x - 2$ introduces one term (since $m = 1$) of the form

$$\frac{C}{x-2}$$

so the partial fraction decomposition is

$$\frac{2x+4}{x^2(x-2)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x-2} \tag{7}$$

Multiplying by $x^2(x-2)$ yields

$$2x+4 = Ax(x-2) + B(x-2) + Cx^2 \tag{8}$$

which, after multiplying out and collecting like powers of $x$, becomes

$$2x+4 = (A+C)x^2 + (-2A+B)x - 2B \tag{9}$$

Setting $x = 0$ in (8) makes the first and third terms drop out and yields $B = -2$, and setting $x = 2$ in (8) makes the first and second terms drop out and yields $C = 2$ (verify). However, there is no substitution in (8) that produces $A$ directly, so we look to Equation (9) to find this value. This can be done by equating the coefficients of $x^2$ on the two sides to obtain

$$A + C = 0 \quad \text{or} \quad A = -C = -2$$

Substituting the values $A = -2$, $B = -2$, and $C = 2$ in (7) yields the partial fraction decomposition

$$\frac{2x+4}{x^2(x-2)} = \frac{-2}{x} + \frac{-2}{x^2} + \frac{2}{x-2}$$

Thus,

$$\int \frac{2x+4}{x^2(x-2)}\,dx = -2\int \frac{dx}{x} - 2\int \frac{dx}{x^2} + 2\int \frac{dx}{x-2}$$
$$= -2\ln|x| + \frac{2}{x} + 2\ln|x-2| + C = 2\ln\left|\frac{x-2}{x}\right| + \frac{2}{x} + C \quad \blacktriangleleft$$

## QUADRATIC FACTORS

If some of the factors of $Q(x)$ are irreducible quadratics, then the contribution of those factors to the partial fraction decomposition of $P(x)/Q(x)$ can be determined from the following rule:

**QUADRATIC FACTOR RULE** For each factor of the form $(ax^2 + bx + c)^m$, the partial fraction decomposition contains the following sum of $m$ partial fractions:

$$\frac{A_1x + B_1}{ax^2 + bx + c} + \frac{A_2x + B_2}{(ax^2 + bx + c)^2} + \cdots + \frac{A_mx + B_m}{(ax^2 + bx + c)^m}$$

where $A_1, A_2, \ldots, A_m, B_1, B_2, \ldots, B_m$ are constants to be determined. In the case where $m = 1$, only the first term in the sum appears.

**Example 3** Evaluate $\displaystyle\int \frac{x^2 + x - 2}{3x^3 - x^2 + 3x - 1}\,dx$.

***Solution.*** The denominator in the integrand can be factored by grouping:

$$3x^3 - x^2 + 3x - 1 = x^2(3x - 1) + (3x - 1) = (3x - 1)(x^2 + 1)$$

By the linear factor rule, the factor $3x - 1$ introduces one term, namely,

$$\frac{A}{3x - 1}$$

and by the quadratic factor rule, the factor $x^2 + 1$ introduces one term, namely,

$$\frac{Bx + C}{x^2 + 1}$$

Thus, the partial fraction decomposition is

$$\frac{x^2 + x - 2}{(3x - 1)(x^2 + 1)} = \frac{A}{3x - 1} + \frac{Bx + C}{x^2 + 1} \tag{10}$$

Multiplying by $(3x - 1)(x^2 + 1)$ yields

$$x^2 + x - 2 = A(x^2 + 1) + (Bx + C)(3x - 1) \tag{11}$$

We could find $A$ by substituting $x = \frac{1}{3}$ to make the last term drop out, and then find the rest of the constants by equating corresponding coefficients. However, in this case it is just as easy to find *all* of the constants by equating coefficients and solving the resulting system. For this purpose we multiply out the right side of (11) and collect like terms:

$$x^2 + x - 2 = (A + 3B)x^2 + (-B + 3C)x + (A - C)$$

Equating corresponding coefficients gives

$$\begin{aligned} A + 3B \qquad &= 1 \\ -B + 3C &= 1 \\ A \qquad - C &= -2 \end{aligned}$$

To solve this system, subtract the third equation from the first to eliminate $A$. Then use the resulting equation together with the second equation to solve for $B$ and $C$. Finally, determine $A$ from the first or third equation. This yields (verify)

$$A = -\frac{7}{5}, \quad B = \frac{4}{5}, \quad C = \frac{3}{5}$$

Thus, (10) becomes

$$\frac{x^2+x-2}{(3x-1)(x^2+1)} = \frac{-\frac{7}{5}}{3x-1} + \frac{\frac{4}{5}x+\frac{3}{5}}{x^2+1}$$

and

$$\int \frac{x^2+x-2}{(3x-1)(x^2+1)}\,dx = -\frac{7}{5}\int \frac{dx}{3x-1} + \frac{4}{5}\int \frac{x}{x^2+1}\,dx + \frac{3}{5}\int \frac{dx}{x^2+1}$$
$$= -\frac{7}{15}\ln|3x-1| + \frac{2}{5}\ln(x^2+1) + \frac{3}{5}\tan^{-1}x + C \quad \blacktriangleleft$$

**TECHNOLOGY MASTERY**

Computer algebra systems have built-in capabilities for finding partial fraction decompositions. If you have a CAS, use it to find the decompositions in Examples 1, 2, and 3.

▶ **Example 4** Evaluate $\displaystyle\int \frac{3x^4+4x^3+16x^2+20x+9}{(x+2)(x^2+3)^2}\,dx$.

***Solution.*** Observe that the integrand is a proper rational function since the numerator has degree 4 and the denominator has degree 5. Thus, the method of partial fractions is applicable. By the linear factor rule, the factor $x+2$ introduces the single term

$$\frac{A}{x+2}$$

and by the quadratic factor rule, the factor $(x^2+3)^2$ introduces two terms (since $m=2$):

$$\frac{Bx+C}{x^2+3} + \frac{Dx+E}{(x^2+3)^2}$$

Thus, the partial fraction decomposition of the integrand is

$$\frac{3x^4+4x^3+16x^2+20x+9}{(x+2)(x^2+3)^2} = \frac{A}{x+2} + \frac{Bx+C}{x^2+3} + \frac{Dx+E}{(x^2+3)^2} \tag{12}$$

Multiplying by $(x+2)(x^2+3)^2$ yields

$$3x^4+4x^3+16x^2+20x+9$$
$$= A(x^2+3)^2 + (Bx+C)(x^2+3)(x+2) + (Dx+E)(x+2) \tag{13}$$

which, after multiplying out and collecting like powers of $x$, becomes

$$3x^4+4x^3+16x^2+20x+9$$
$$= (A+B)x^4 + (2B+C)x^3 + (6A+3B+2C+D)x^2$$
$$+ (6B+3C+2D+E)x + (9A+6C+2E) \tag{14}$$

Equating corresponding coefficients in (14) yields the following system of five linear equations in five unknowns:

$$\begin{aligned} A+B &= 3 \\ 2B+C &= 4 \\ 6A+3B+2C+D &= 16 \\ 6B+3C+2D+E &= 20 \\ 9A+6C+2E &= 9 \end{aligned} \tag{15}$$

Efficient methods for solving systems of linear equations such as this are studied in a branch of mathematics called ***linear algebra***; those methods are outside the scope of this text. However, as a practical matter most linear systems of any size are solved by computer, and most computer algebra systems have commands that in many cases can solve linear systems exactly. In this particular case we can simplify the work by first substituting $x=-2$

in (13), which yields $A = 1$. Substituting this known value of $A$ in (15) yields the simpler system

$$\begin{aligned} B &= 2 \\ 2B + C &= 4 \\ 3B + 2C + D &= 10 \\ 6B + 3C + 2D + E &= 20 \\ 6C + 2E &= 0 \end{aligned} \tag{16}$$

This system can be solved by starting at the top and working down, first substituting $B = 2$ in the second equation to get $C = 0$, then substituting the known values of $B$ and $C$ in the third equation to get $D = 4$, and so forth. This yields

$$A = 1, \quad B = 2, \quad C = 0, \quad D = 4, \quad E = 0$$

Thus, (12) becomes

$$\frac{3x^4 + 4x^3 + 16x^2 + 20x + 9}{(x+2)(x^2+3)^2} = \frac{1}{x+2} + \frac{2x}{x^2+3} + \frac{4x}{(x^2+3)^2}$$

and so

$$\begin{aligned} &\int \frac{3x^4 + 4x^3 + 16x^2 + 20x + 9}{(x+2)(x^2+3)^2}\,dx \\ &\quad = \int \frac{dx}{x+2} + \int \frac{2x}{x^2+3}\,dx + 4\int \frac{x}{(x^2+3)^2}\,dx \\ &\quad = \ln|x+2| + \ln(x^2+3) - \frac{2}{x^2+3} + C \end{aligned}$$ ◀

## INTEGRATING IMPROPER RATIONAL FUNCTIONS

Although the method of partial fractions only applies to proper rational functions, an improper rational function can be integrated by performing a long division and expressing the function as the quotient plus the remainder over the divisor. The remainder over the divisor will be a proper rational function, which can then be decomposed into partial fractions. This idea is illustrated in the following example.

**▶ Example 5** Evaluate $\displaystyle\int \frac{3x^4 + 3x^3 - 5x^2 + x - 1}{x^2 + x - 2}\,dx$.

***Solution.*** The integrand is an improper rational function since the numerator has degree 4 and the denominator has degree 2. Thus, we first perform the long division

$$\begin{array}{r} 3x^2 \quad +1 \\ x^2+x-2 \;\overline{)\; 3x^4+3x^3-5x^2+x-1} \\ \underline{3x^4+3x^3-6x^2} \\ x^2+x-1 \\ \underline{x^2+x-2} \\ 1 \end{array}$$

It follows that the integrand can be expressed as

$$\frac{3x^4 + 3x^3 - 5x^2 + x - 1}{x^2 + x - 2} = (3x^2 + 1) + \frac{1}{x^2 + x - 2}$$

and hence

$$\int \frac{3x^4 + 3x^3 - 5x^2 + x - 1}{x^2 + x - 2}\,dx = \int (3x^2 + 1)\,dx + \int \frac{dx}{x^2 + x - 2}$$

The second integral on the right now involves a proper rational function and can thus be evaluated by a partial fraction decomposition. Using the result of Example 1 we obtain

$$\int \frac{3x^4+3x^3-5x^2+x-1}{x^2+x-2}\,dx = x^3+x+\frac{1}{3}\ln\left|\frac{x-1}{x+2}\right|+C \quad \blacktriangleleft$$

## CONCLUDING REMARKS

There are some cases in which the method of partial fractions is inappropriate. For example, it would be inefficient to use partial fractions to perform the integration

$$\int \frac{3x^2+2}{x^3+2x-8}\,dx = \ln|x^3+2x-8|+C$$

since the substitution $u = x^3+2x-8$ is more direct. Similarly, the integration

$$\int \frac{2x-1}{x^2+1}\,dx = \int \frac{2x}{x^2+1}\,dx - \int \frac{dx}{x^2+1} = \ln(x^2+1)-\tan^{-1}x+C$$

requires only a little algebra since the integrand is already in partial fraction form.

## QUICK CHECK EXERCISES 7.5 (See page 523 for answers.)

1. A partial fraction is a rational function of the form _____ or of the form _____.
2. (a) What is a proper rational function?
   (b) What condition must the degree of the numerator and the degree of the denominator of a rational function satisfy for the method of partial fractions to be applicable directly?
   (c) If the condition in part (b) is not satisfied, what must you do if you want to use partial fractions?
3. Suppose that the function $f(x) = P(x)/Q(x)$ is a proper rational function.
   (a) For each factor of $Q(x)$ of the form $(ax+b)^m$, the partial fraction decomposition of $f$ contains the following sum of $m$ partial fractions: _____
   (b) For each factor of $Q(x)$ of the form $(ax^2+bx+c)^m$, where $ax^2+bx+c$ is an irreducible quadratic, the partial fraction decomposition of $f$ contains the following sum of $m$ partial fractions: _____
4. Complete the partial fraction decomposition.
   (a) $\dfrac{-3}{(x+1)(2x-1)} = \dfrac{A}{x+1} - \dfrac{2}{2x-1}$
   (b) $\dfrac{2x^2-3x}{(x^2+1)(3x+2)} = \dfrac{B}{3x+2} - \dfrac{1}{x^2+1}$
5. Evaluate the integral.
   (a) $\displaystyle\int \frac{3}{(x+1)(1-2x)}\,dx$ (b) $\displaystyle\int \frac{2x^2-3x}{(x^2+1)(3x+2)}\,dx$

## EXERCISE SET 7.5 C CAS

**1–8** Write out the form of the partial fraction decomposition. (Do not find the numerical values of the coefficients.)

1. $\dfrac{3x-1}{(x-3)(x+4)}$
2. $\dfrac{5}{x(x^2-4)}$
3. $\dfrac{2x-3}{x^3-x^2}$
4. $\dfrac{x^2}{(x+2)^3}$
5. $\dfrac{1-x^2}{x^3(x^2+2)}$
6. $\dfrac{3x}{(x-1)(x^2+6)}$
7. $\dfrac{4x^3-x}{(x^2+5)^2}$
8. $\dfrac{1-3x^4}{(x-2)(x^2+1)^2}$

**9–34** Evaluate the integral.

9. $\displaystyle\int \frac{dx}{x^2-3x-4}$
10. $\displaystyle\int \frac{dx}{x^2-6x-7}$
11. $\displaystyle\int \frac{11x+17}{2x^2+7x-4}\,dx$
12. $\displaystyle\int \frac{5x-5}{3x^2-8x-3}\,dx$
13. $\displaystyle\int \frac{2x^2-9x-9}{x^3-9x}\,dx$
14. $\displaystyle\int \frac{dx}{x(x^2-1)}$
15. $\displaystyle\int \frac{x^2-8}{x+3}\,dx$
16. $\displaystyle\int \frac{x^2+1}{x-1}\,dx$
17. $\displaystyle\int \frac{3x^2-10}{x^2-4x+4}\,dx$
18. $\displaystyle\int \frac{x^2}{x^2-3x+2}\,dx$
19. $\displaystyle\int \frac{2x-3}{x^2-3x-10}\,dx$
20. $\displaystyle\int \frac{3x+1}{3x^2+2x-1}\,dx$
21. $\displaystyle\int \frac{x^5+x^2+2}{x^3-x}\,dx$
22. $\displaystyle\int \frac{x^5-4x^3+1}{x^3-4x}\,dx$
23. $\displaystyle\int \frac{2x^2+3}{x(x-1)^2}\,dx$
24. $\displaystyle\int \frac{3x^2-x+1}{x^3-x^2}\,dx$

**25.** $\displaystyle\int \frac{2x^2 - 10x + 4}{(x+1)(x-3)^2}\,dx$

**26.** $\displaystyle\int \frac{2x^2 - 2x - 1}{x^3 - x^2}\,dx$

**27.** $\displaystyle\int \frac{x^2}{(x+1)^3}\,dx$

**28.** $\displaystyle\int \frac{2x^2 + 3x + 3}{(x+1)^3}\,dx$

**29.** $\displaystyle\int \frac{2x^2 - 1}{(4x-1)(x^2+1)}\,dx$

**30.** $\displaystyle\int \frac{dx}{x^3 + 2x}$

**31.** $\displaystyle\int \frac{x^3 + 3x^2 + x + 9}{(x^2+1)(x^2+3)}\,dx$

**32.** $\displaystyle\int \frac{x^3 + x^2 + x + 2}{(x^2+1)(x^2+2)}\,dx$

**33.** $\displaystyle\int \frac{x^3 - 2x^2 + 2x - 2}{x^2 + 1}\,dx$

**34.** $\displaystyle\int \frac{x^4 + 6x^3 + 10x^2 + x}{x^2 + 6x + 10}\,dx$

**35–38 True–False** Determine whether the statement is true or false. Explain your answer.

**35.** The technique of partial fractions is used for integrals whose integrands are ratios of polynomials.

**36.** The integrand in

$$\int \frac{3x^4 + 5}{(x^2+1)^2}\,dx$$

is a proper rational function.

**37.** The partial fraction decomposition of

$$\frac{2x+3}{x^2} \quad \text{is} \quad \frac{2}{x} + \frac{3}{x^2}$$

**38.** If $f(x) = P(x)/(x+5)^3$ is a proper rational function, then the partial fraction decomposition of $f(x)$ has terms with constant numerators and denominators $(x+5)$, $(x+5)^2$, and $(x+5)^3$.

**39–42** Evaluate the integral by making a substitution that converts the integrand to a rational function.

**39.** $\displaystyle\int \frac{\cos\theta}{\sin^2\theta + 4\sin\theta - 5}\,d\theta$

**40.** $\displaystyle\int \frac{e^t}{e^{2t} - 4}\,dt$

**41.** $\displaystyle\int \frac{e^{3x}}{e^{2x} + 4}\,dx$

**42.** $\displaystyle\int \frac{5 + 2\ln x}{x(1 + \ln x)^2}\,dx$

**43.** Find the volume of the solid generated when the region enclosed by $y = x^2/(9 - x^2)$, $y = 0$, $x = 0$, and $x = 2$ is revolved about the $x$-axis.

**44.** Find the area of the region under the curve $y = 1/(1 + e^x)$, over the interval $[-\ln 5, \ln 5]$. [*Hint:* Make a substitution that converts the integrand to a rational function.]

C **45–46** Use a CAS to evaluate the integral in two ways: (i) integrate directly; (ii) use the CAS to find the partial fraction decomposition and integrate the decomposition. Integrate by hand to check the results.

**45.** $\displaystyle\int \frac{x^2 + 1}{(x^2 + 2x + 3)^2}\,dx$

**46.** $\displaystyle\int \frac{x^5 + x^4 + 4x^3 + 4x^2 + 4x + 4}{(x^2+2)^3}\,dx$

C **47–48** Integrate by hand and check your answers using a CAS.

**47.** $\displaystyle\int \frac{dx}{x^4 - 3x^3 - 7x^2 + 27x - 18}$

**48.** $\displaystyle\int \frac{dx}{16x^3 - 4x^2 + 4x - 1}$

**FOCUS ON CONCEPTS**

**49.** Show that

$$\int_0^1 \frac{x}{x^4 + 1}\,dx = \frac{\pi}{8}$$

**50.** Use partial fractions to derive the integration formula

$$\int \frac{1}{a^2 - x^2}\,dx = \frac{1}{2a}\ln\left|\frac{a+x}{a-x}\right| + C$$

**51.** Suppose that $ax^2 + bx + c$ is a quadratic polynomial and that the integration

$$\int \frac{1}{ax^2 + bx + c}\,dx$$

produces a function with no inverse tangent terms. What does this tell you about the roots of the polynomial?

**52.** Suppose that $ax^2 + bx + c$ is a quadratic polynomial and that the integration

$$\int \frac{1}{ax^2 + bx + c}\,dx$$

produces a function with neither logarithmic nor inverse tangent terms. What does this tell you about the roots of the polynomial?

**53.** Does there exist a quadratic polynomial $ax^2 + bx + c$ such that the integration

$$\int \frac{x}{ax^2 + bx + c}\,dx$$

produces a function with no logarithmic terms? If so, give an example; if not, explain why no such polynomial can exist.

**54. Writing** Suppose that $P(x)$ is a cubic polynomial. State the general form of the partial fraction decomposition for

$$f(x) = \frac{P(x)}{(x+5)^4}$$

and state the implications of this decomposition for evaluating the integral $\int f(x)\,dx$.

**55. Writing** Consider the functions

$$f(x) = \frac{1}{x^2 - 4} \quad \text{and} \quad g(x) = \frac{x}{x^2 - 4}$$

Each of the integrals $\int f(x)\,dx$ and $\int g(x)\,dx$ can be evaluated using partial fractions and using at least one other integration technique. Demonstrate two different techniques for evaluating each of these integrals, and then discuss the considerations that would determine which technique you would use.

## ✔ QUICK CHECK ANSWERS 7.5

**1.** $\dfrac{A}{(ax+b)^k}$; $\dfrac{Ax+B}{(ax^2+bx+c)^k}$ **2.** (a) A proper rational function is a rational function in which the degree of the numerator is less than the degree of the denominator. (b) The degree of the numerator must be less than the degree of the denominator. (c) Divide the denominator into the numerator, which results in the sum of a polynomial and a proper rational function.

**3.** (a) $\dfrac{A_1}{ax+b}+\dfrac{A_2}{(ax+b)^2}+\cdots+\dfrac{A_m}{(ax+b)^m}$ (b) $\dfrac{A_1x+B_1}{ax^2+bx+c}+\dfrac{A_2x+B_2}{(ax^2+bx+c)^2}+\cdots+\dfrac{A_mx+B_m}{(ax^2+bx+c)^m}$

**4.** (a) $A=1$ (b) $B=2$

# 7.6 USING COMPUTER ALGEBRA SYSTEMS AND TABLES OF INTEGRALS

*In this section we will discuss how to integrate using tables, and we will see some special substitutions to try when an integral doesn't match any of the forms in an integral table. In particular, we will discuss a method for integrating rational functions of* $\sin x$ *and* $\cos x$. *We will also address some of the issues that relate to using computer algebra systems for integration. Readers who are not using computer algebra systems can skip that material.*

## INTEGRAL TABLES

Tables of integrals are useful for eliminating tedious hand computation. The endpapers of this text contain a relatively brief table of integrals that we will refer to as the ***Endpaper Integral Table***; more comprehensive tables are published in standard reference books such as the *CRC Standard Mathematical Tables and Formulae*, CRC Press, Inc., 2002.

All integral tables have their own scheme for classifying integrals according to the form of the integrand. For example, the Endpaper Integral Table classifies the integrals into 15 categories; *Basic Functions*, *Reciprocals of Basic Functions*, *Powers of Trigonometric Functions*, *Products of Trigonometric Functions*, and so forth. The first step in working with tables is to read through the classifications so that you understand the classification scheme and know where to look in the table for integrals of different types.

## PERFECT MATCHES

If you are lucky, the integral you are attempting to evaluate will match up perfectly with one of the forms in the table. However, when looking for matches you may have to make an adjustment for the variable of integration. For example, the integral

$$\int x^2 \sin x\,dx$$

is a perfect match with Formula (46) in the Endpaper Integral Table, except for the letter used for the variable of integration. Thus, to apply Formula (46) to the given integral we need to change the variable of integration in the formula from $u$ to $x$. With that minor modification we obtain

$$\int x^2 \sin x\,dx = 2x\sin x+(2-x^2)\cos x+C$$

Here are some more examples of perfect matches.

▶ **Example 1** Use the Endpaper Integral Table to evaluate

$$\text{(a)} \int \sin 7x \cos 2x \, dx \qquad \text{(b)} \int x^2\sqrt{7+3x}\, dx$$

$$\text{(c)} \int \frac{\sqrt{2-x^2}}{x}\, dx \qquad \text{(d)} \int (x^3+7x+1)\sin \pi x \, dx$$

***Solution (a).*** The integrand can be classified as a product of trigonometric functions. Thus, from Formula (40) with $m = 7$ and $n = 2$ we obtain

$$\int \sin 7x \cos 2x \, dx = -\frac{\cos 9x}{18} - \frac{\cos 5x}{10} + C$$

***Solution (b).*** The integrand can be classified as a power of $x$ multiplying $\sqrt{a+bx}$. Thus, from Formula (103) with $a = 7$ and $b = 3$ we obtain

$$\int x^2\sqrt{7+3x}\, dx = \frac{2}{2835}(135x^2 - 252x + 392)(7+3x)^{3/2} + C$$

***Solution (c).*** The integrand can be classified as a power of $x$ dividing $\sqrt{a^2-x^2}$. Thus, from Formula (79) with $a = \sqrt{2}$ we obtain

$$\int \frac{\sqrt{2-x^2}}{x}\, dx = \sqrt{2-x^2} - \sqrt{2}\ln\left|\frac{\sqrt{2}+\sqrt{2-x^2}}{x}\right| + C$$

***Solution (d).*** The integrand can be classified as a polynomial multiplying a trigonometric function. Thus, we apply Formula (58) with $p(x) = x^3 + 7x + 1$ and $a = \pi$. The successive nonzero derivatives of $p(x)$ are

$$p'(x) = 3x^2 + 7, \quad p''(x) = 6x, \quad p'''(x) = 6$$

and so

$$\int (x^3+7x+1)\sin \pi x \, dx$$
$$= -\frac{x^3+7x+1}{\pi}\cos \pi x + \frac{3x^2+7}{\pi^2}\sin \pi x + \frac{6x}{\pi^3}\cos \pi x - \frac{6}{\pi^4}\sin \pi x + C \quad ◀$$

## MATCHES REQUIRING SUBSTITUTIONS

Sometimes an integral that does not match any table entry can be made to match by making an appropriate substitution.

▶ **Example 2** Use the Endpaper Integral Table to evaluate

$$\text{(a)} \int e^{\pi x}\sin^{-1}(e^{\pi x})\, dx \qquad \text{(b)} \int x\sqrt{x^2-4x+5}\, dx$$

***Solution (a).*** The integrand does not even come close to matching any of the forms in the table. However, a little thought suggests the substitution

$$u = e^{\pi x}, \quad du = \pi e^{\pi x}\, dx$$

from which we obtain

$$\int e^{\pi x} \sin^{-1}(e^{\pi x})\,dx = \frac{1}{\pi}\int \sin^{-1} u\,du$$

The integrand is now a basic function, and Formula (7) yields

$$\begin{aligned}\int e^{\pi x} \sin^{-1}(e^{\pi x})\,dx &= \frac{1}{\pi}\left[u \sin^{-1} u + \sqrt{1-u^2}\right] + C \\ &= \frac{1}{\pi}\left[e^{\pi x} \sin^{-1}(e^{\pi x}) + \sqrt{1-e^{2\pi x}}\right] + C\end{aligned}$$

***Solution (b).*** Again, the integrand does not closely match any of the forms in the table. However, a little thought suggests that it may be possible to bring the integrand closer to the form $x\sqrt{x^2+a^2}$ by completing the square to eliminate the term involving $x$ inside the radical. Doing this yields

$$\int x\sqrt{x^2-4x+5}\,dx = \int x\sqrt{(x^2-4x+4)+1}\,dx = \int x\sqrt{(x-2)^2+1}\,dx \qquad (1)$$

At this point we are closer to the form $x\sqrt{x^2+a^2}$, but we are not quite there because of the $(x-2)^2$ rather than $x^2$ inside the radical. However, we can resolve that problem with the substitution

$$u = x-2, \quad du = dx$$

With this substitution we have $x = u+2$, so (1) can be expressed in terms of $u$ as

$$\int x\sqrt{x^2-4x+5}\,dx = \int (u+2)\sqrt{u^2+1}\,du = \int u\sqrt{u^2+1}\,du + 2\int \sqrt{u^2+1}\,du$$

The first integral on the right is now a perfect match with Formula (84) with $a = 1$, and the second is a perfect match with Formula (72) with $a = 1$. Thus, applying these formulas we obtain

$$\int x\sqrt{x^2-4x+5}\,dx = \tfrac{1}{3}(u^2+1)^{3/2} + 2\left[\tfrac{1}{2}u\sqrt{u^2+1} + \tfrac{1}{2}\ln(u+\sqrt{u^2+1})\right] + C$$

If we now replace $u$ by $x-2$ (in which case $u^2+1 = x^2-4x+5$), we obtain

$$\begin{aligned}\int x\sqrt{x^2-4x+5}\,dx = \tfrac{1}{3}(x^2-4x+5)^{3/2} + (x-2)\sqrt{x^2-4x+5} \\ + \ln\left(x-2+\sqrt{x^2-4x+5}\right) + C\end{aligned}$$

Although correct, this form of the answer has an unnecessary mixture of radicals and fractional exponents. If desired, we can "clean up" the answer by writing

$$(x^2-4x+5)^{3/2} = (x^2-4x+5)\sqrt{x^2-4x+5}$$

from which it follows that (verify)

$$\begin{aligned}\int x\sqrt{x^2-4x+5}\,dx = \tfrac{1}{3}(x^2-x-1)\sqrt{x^2-4x+5} \\ + \ln\left(x-2+\sqrt{x^2-4x+5}\right) + C \quad \blacktriangleleft\end{aligned}$$

## MATCHES REQUIRING REDUCTION FORMULAS

In cases where the entry in an integral table is a reduction formula, that formula will have to be applied first to reduce the given integral to a form in which it can be evaluated.

▶ **Example 3** Use the Endpaper Integral Table to evaluate $\displaystyle\int \frac{x^3}{\sqrt{1+x}}\,dx$.

***Solution.*** The integrand can be classified as a power of $x$ multiplying the reciprocal of $\sqrt{a+bx}$. Thus, from Formula (107) with $a=1$, $b=1$, and $n=3$, followed by Formula (106), we obtain

$$\begin{aligned}\int \frac{x^3}{\sqrt{1+x}}\,dx &= \frac{2x^3\sqrt{1+x}}{7} - \frac{6}{7}\int \frac{x^2}{\sqrt{1+x}}\,dx \\ &= \frac{2x^3\sqrt{1+x}}{7} - \frac{6}{7}\left[\frac{2}{15}(3x^2-4x+8)\sqrt{1+x}\right] + C \\ &= \left(\frac{2x^3}{7} - \frac{12x^2}{35} + \frac{16x}{35} - \frac{32}{35}\right)\sqrt{1+x} + C \quad \blacktriangleleft\end{aligned}$$

## SPECIAL SUBSTITUTIONS

The Endpaper Integral Table has numerous entries involving an exponent of $3/2$ or involving square roots (exponent $1/2$), but it has no entries with other fractional exponents. However, integrals involving fractional powers of $x$ can often be simplified by making the substitution $u = x^{1/n}$ in which $n$ is the least common multiple of the denominators of the exponents. The resulting integral will then involve integer powers of $u$.

▶ **Example 4** Evaluate

$$\text{(a)}\ \int \frac{\sqrt{x}}{1+\sqrt[3]{x}}\,dx \qquad \text{(b)}\ \int \sqrt{1+e^x}\,dx$$

***Solution (a).*** The integrand contains $x^{1/2}$ and $x^{1/3}$, so we make the substitution $u = x^{1/6}$, from which we obtain

$$x = u^6, \quad dx = 6u^5\,du$$

Thus,

$$\int \frac{\sqrt{x}}{1+\sqrt[3]{x}}\,dx = \int \frac{(u^6)^{1/2}}{1+(u^6)^{1/3}}(6u^5)\,du = 6\int \frac{u^8}{1+u^2}\,du$$

By long division

$$\frac{u^8}{1+u^2} = u^6 - u^4 + u^2 - 1 + \frac{1}{1+u^2}$$

from which it follows that

$$\begin{aligned}\int \frac{\sqrt{x}}{1+\sqrt[3]{x}}\,dx &= 6\int \left(u^6 - u^4 + u^2 - 1 + \frac{1}{1+u^2}\right)du \\ &= \tfrac{6}{7}u^7 - \tfrac{6}{5}u^5 + 2u^3 - 6u + 6\tan^{-1}u + C \\ &= \tfrac{6}{7}x^{7/6} - \tfrac{6}{5}x^{5/6} + 2x^{1/2} - 6x^{1/6} + 6\tan^{-1}(x^{1/6}) + C\end{aligned}$$

***Solution (b).*** The integral does not match any of the forms in the Endpaper Integral Table. However, the table does include several integrals containing $\sqrt{a+bu}$. This suggests the substitution $u = e^x$, from which we obtain

$$x = \ln u, \quad dx = \frac{1}{u}\,du$$

Thus, from Formula (110) with $a = 1$ and $b = 1$, followed by Formula (108), we obtain

$$\begin{aligned}\int \sqrt{1+e^x}\,dx &= \int \frac{\sqrt{1+u}}{u}\,du \\ &= 2\sqrt{1+u} + \int \frac{du}{u\sqrt{1+u}} \\ &= 2\sqrt{1+u} + \ln\left|\frac{\sqrt{1+u}-1}{\sqrt{1+u}+1}\right| + C \\ &= 2\sqrt{1+e^x} + \ln\left[\frac{\sqrt{1+e^x}-1}{\sqrt{1+e^x}+1}\right] + C\end{aligned}$$

Absolute value not needed ◀

Try finding the antiderivative in Example 4(b) using the substitution

$$u = \sqrt{1+e^x}$$

Functions that consist of finitely many sums, differences, quotients, and products of $\sin x$ and $\cos x$ are called ***rational functions of sin x and cos x***. Some examples are

$$\frac{\sin x + 3\cos^2 x}{\cos x + 4\sin x}, \quad \frac{\sin x}{1+\cos x - \cos^2 x}, \quad \frac{3\sin^5 x}{1+4\sin x}$$

The Endpaper Integral Table gives a few formulas for integrating rational functions of $\sin x$ and $\cos x$ under the heading *Reciprocals of Basic Functions*. For example, it follows from Formula (18) that

$$\int \frac{1}{1+\sin x}\,dx = \tan x - \sec x + C \tag{2}$$

However, since the integrand is a rational function of $\sin x$, it may be desirable in a particular application to express the value of the integral in terms of $\sin x$ and $\cos x$ and rewrite (2) as

$$\int \frac{1}{1+\sin x}\,dx = \frac{\sin x - 1}{\cos x} + C$$

Many rational functions of $\sin x$ and $\cos x$ can be evaluated by an ingenious method that was discovered by the mathematician Karl Weierstrass (see p. 102 for biography). The idea is to make the substitution

$$u = \tan(x/2), \quad -\pi/2 < x/2 < \pi/2$$

from which it follows that

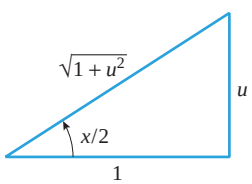
$$x = 2\tan^{-1} u, \quad dx = \frac{2}{1+u^2}\,du$$

To implement this substitution we need to express $\sin x$ and $\cos x$ in terms of $u$. For this purpose we will use the identities

$$\sin x = 2\sin(x/2)\cos(x/2) \tag{3}$$

$$\cos x = \cos^2(x/2) - \sin^2(x/2) \tag{4}$$

and the following relationships suggested by Figure 7.6.1:



▲ Figure 7.6.1

$$\sin(x/2) = \frac{u}{\sqrt{1+u^2}} \quad \text{and} \quad \cos(x/2) = \frac{1}{\sqrt{1+u^2}}$$

Substituting these expressions in (3) and (4) yields

$$\sin x = 2\left(\frac{u}{\sqrt{1+u^2}}\right)\left(\frac{1}{\sqrt{1+u^2}}\right) = \frac{2u}{1+u^2}$$

$$\cos x = \left(\frac{1}{\sqrt{1+u^2}}\right)^2 - \left(\frac{u}{\sqrt{1+u^2}}\right)^2 = \frac{1-u^2}{1+u^2}$$

In summary, we have shown that the substitution $u = \tan(x/2)$ can be implemented in a rational function of $\sin x$ and $\cos x$ by letting

$$\sin x = \frac{2u}{1+u^2}, \quad \cos x = \frac{1-u^2}{1+u^2}, \quad dx = \frac{2}{1+u^2}\,du \tag{5}$$

**▶ Example 5** Evaluate $\displaystyle\int \frac{dx}{1-\sin x+\cos x}$.

***Solution.*** The integrand is a rational function of $\sin x$ and $\cos x$ that does not match any of the formulas in the Endpaper Integral Table, so we make the substitution $u = \tan(x/2)$. Thus, from (5) we obtain

$$\begin{aligned}\int \frac{dx}{1-\sin x+\cos x} &= \int \frac{\dfrac{2\,du}{1+u^2}}{1-\left(\dfrac{2u}{1+u^2}\right)+\left(\dfrac{1-u^2}{1+u^2}\right)} \\ &= \int \frac{2\,du}{(1+u^2)-2u+(1-u^2)} \\ &= \int \frac{du}{1-u} = -\ln|1-u|+C = -\ln|1-\tan(x/2)|+C \quad \blacktriangleleft\end{aligned}$$

The substitution $u = \tan(x/2)$ will convert any rational function of $\sin x$ and $\cos x$ to an ordinary rational function of $u$. However, the method can lead to cumbersome partial fraction decompositions, so it may be worthwhile to consider other methods as well when hand computations are being used.

## INTEGRATING WITH COMPUTER ALGEBRA SYSTEMS

Integration tables are rapidly giving way to computerized integration using computer algebra systems. However, as with many powerful tools, a knowledgeable operator is an important component of the system.

Sometimes computer algebra systems do not produce the most general form of the indefinite integral. For example, the integral formula

$$\int \frac{dx}{x-1} = \ln|x-1|+C$$

which can be obtained by inspection or by using the substitution $u = x-1$, is valid for $x > 1$ or for $x < 1$. However, not all computer algebra systems produce this form of the answer. Some typical answers produced by various implementations of *Mathematica*, *Maple*, and the CAS on a handheld calculator are

$$\ln(-1+x), \quad \ln(x-1), \quad \ln(|x-1|)$$

Observe that none of the systems include the constant of integration—the answer produced is a particular antiderivative and not the most general antiderivative (indefinite integral). Observe also that only one of these answers includes the absolute value signs; the antiderivatives produced by the other systems are valid only for $x > 1$. All systems, however, are able to calculate the definite integral

$$\int_0^{1/2} \frac{dx}{x-1} = -\ln 2$$

correctly. Now let us examine how these systems handle the integral

$$\begin{aligned}\int x\sqrt{x^2-4x+5}\,dx = \tfrac{1}{3}(x^2-x-1)\sqrt{x^2-4x+5} \\ +\ln\left(x-2+\sqrt{x^2-4x+5}\right)\end{aligned} \tag{6}$$

which we obtained in Example 2(b) (with the constant of integration included). Some CAS implementations produce this result in slightly different algebraic forms, but a version of *Maple* produces the result

$$\int x\sqrt{x^2-4x+5}\,dx = \tfrac{1}{3}(x^2-4x+5)^{3/2} + \tfrac{1}{2}(2x-4)\sqrt{x^2-4x+5} + \sinh^{-1}(x-2)$$

This can be rewritten as (6) by expressing the fractional exponent in radical form and expressing $\sinh^{-1}(x-2)$ in logarithmic form using Theorem 6.9.4 (verify). A version of *Mathematica* produces the result

$$\int x\sqrt{x^2-4x+5}\,dx = \tfrac{1}{3}(x^2-x-1)\sqrt{x^2-4x+5} - \sinh^{-1}(2-x)$$

which can be rewritten in form (6) by using Theorem 6.9.4 together with the identity $\sinh^{-1}(-x) = -\sinh^{-1} x$ (verify).

Computer algebra systems can sometimes produce inconvenient or unnatural answers to integration problems. For example, various computer algebra systems produced the following results when asked to integrate $(x+1)^7$:

$$\frac{(x+1)^8}{8}, \quad \frac{1}{8}x^8 + x^7 + \frac{7}{2}x^6 + 7x^5 + \frac{35}{4}x^4 + 7x^3 + \frac{7}{2}x^2 + x \tag{7}$$

Expanding the expression $\dfrac{(x+1)^8}{8}$ produces a constant term of $\frac{1}{8}$, whereas the second expression in (7) has no constant term. What is the explanation?

The first form is in keeping with the hand computation

$$\int (x+1)^7\,dx = \frac{(x+1)^8}{8} + C$$

that uses the substitution $u = x+1$, whereas the second form is based on expanding $(x+1)^7$ and integrating term by term.

In Example 2(a) of Section 7.3 we showed that

$$\int \sin^4 x \cos^5 x\,dx = \tfrac{1}{5}\sin^5 x - \tfrac{2}{7}\sin^7 x + \tfrac{1}{9}\sin^9 x + C$$

However, a version of *Mathematica* integrates this as

$$\tfrac{3}{128}\sin x - \tfrac{1}{192}\sin 3x - \tfrac{1}{320}\sin 5x + \tfrac{1}{1792}\sin 7x + \tfrac{1}{2304}\sin 9x$$

whereas other computer algebra systems essentially integrate it as

$$-\tfrac{1}{9}\sin^3 x\cos^6 x - \tfrac{1}{21}\sin x\cos^6 x + \tfrac{1}{105}\cos^4 x\sin x + \tfrac{4}{315}\cos^2 x\sin x + \tfrac{8}{315}\sin x$$

Although these three results look quite different, they can be obtained from one another using appropriate trigonometric identities.

## COMPUTER ALGEBRA SYSTEMS HAVE LIMITATIONS

A computer algebra system combines a set of integration rules (such as substitution) with a library of functions that it can use to construct antiderivatives. Such libraries contain elementary functions, such as polynomials, rational functions, trigonometric functions, as well as various nonelementary functions that arise in engineering, physics, and other applied fields. Just as our Endpaper Integral Table has only 121 indefinite integrals, these libraries are not exhaustive of all possible integrands. If the system cannot manipulate the integrand to a form matching one in its library, the program will give some indication that it cannot evaluate the integral. For example, when asked to evaluate the integral

$$\int (1+\ln x)\sqrt{1+(x\ln x)^2}\,dx \tag{8}$$

all of the systems mentioned above respond by displaying some form of the unevaluated integral as an answer, indicating that they could not perform the integration.

Sometimes computer algebra systems respond by expressing an integral in terms of another integral. For example, if you try to integrate $e^{x^2}$ using *Mathematica*, *Maple*, or

**TECHNOLOGY MASTERY**

Sometimes integrals that cannot be evaluated by a CAS in their given form can be evaluated by first rewriting them in a different form or by making a substitution. If you have a CAS, make a $u$-substitution in (8) that will enable you to evaluate the integral with your CAS. Then evaluate the integral.

*Sage*, you will obtain an expression involving erf (which stands for ***error function***). The function $\operatorname{erf}(x)$ is defined as

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2}\, dt$$

so all three programs essentially rewrite the given integral in terms of a closely related integral. From one point of view this is what we did in integrating $1/x$, since the natural logarithm function is (formally) defined as

$$\ln x = \int_1^x \frac{1}{t}\, dt$$

(see Section 5.10).

▶ **Example 6** A particle moves along an $x$-axis in such a way that its velocity $v(t)$ at time $t$ is

$$v(t) = 30\cos^7 t \sin^4 t \quad (t \geq 0)$$

Graph the position versus time curve for the particle, given that the particle is at $x = 1$ when $t = 0$.

***Solution.*** Since $dx/dt = v(t)$ and $x = 1$ when $t = 0$, the position function $x(t)$ is given by

$$x(t) = 1 + \int_0^t v(s)\, ds$$

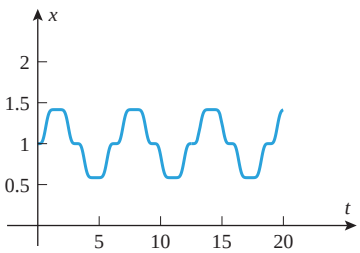
Some computer algebra systems will allow this expression to be entered directly into a command for plotting functions, but it is often more efficient to perform the integration first. The authors' integration utility yields

$$\begin{aligned} x &= \int 30\cos^7 t \sin^4 t\, dt \\ &= -\tfrac{30}{11}\sin^{11} t + 10\sin^9 t - \tfrac{90}{7}\sin^7 t + 6\sin^5 t + C \end{aligned}$$

where we have added the required constant of integration. Using the initial condition $x(0) = 1$, we substitute the values $x = 1$ and $t = 0$ into this equation to find that $C = 1$, so

$$x(t) = -\tfrac{30}{11}\sin^{11} t + 10\sin^9 t - \tfrac{90}{7}\sin^7 t + 6\sin^5 t + 1 \quad (t \geq 0)$$

The graph of $x$ versus $t$ is shown in Figure 7.6.2. ◀



▲ Figure 7.6.2

## ✔ QUICK CHECK EXERCISES 7.6 (See page 533 for answers.)

**1.** Find an integral formula in the Endpaper Integral Table that can be used to evaluate the integral. Do not evaluate the integral.

(a) $\displaystyle\int \frac{2x}{3x+4}\, dx$ _____

(b) $\displaystyle\int \frac{1}{x\sqrt{5x-4}}\, dx$ _____

(c) $\displaystyle\int x\sqrt{3x+2}\, dx$ _____

(d) $\displaystyle\int x^2 \ln x\, dx$ _____

**2.** In each part, make the indicated $u$-substitution, and then find an integral formula in the Endpaper Integral Table that can be used to evaluate the integral. Do not evaluate the integral.

(a) $\displaystyle\int \frac{x}{1+e^{x^2}}\, dx;\ u = x^2$ _____

(b) $\displaystyle\int e^{\sqrt{x}}\, dx;\ u = \sqrt{x}$ _____

(c) $\displaystyle\int \frac{e^x}{1+\sin(e^x)}\, dx;\ u = e^x$ _____

(d) $\displaystyle\int \frac{1}{(1-4x^2)^{3/2}}\, dx;\ u = 2x$ _____

**3.** In each part, use the Endpaper Integral Table to evaluate the integral. (If necessary, first make an appropriate substitution or complete the square.) *(cont.)*

(a) $\displaystyle\int \frac{1}{4-x^2}\,dx =$ _____

(b) $\displaystyle\int \cos 2x \cos x\,dx =$ _____

(c) $\displaystyle\int \frac{e^{3x}}{\sqrt{1-e^{2x}}}\,dx =$ _____

(d) $\displaystyle\int \frac{x}{x^2-4x+8}\,dx =$ _____

## EXERCISE SET 7.6 C CAS

C **1–24** (a) Use the Endpaper Integral Table to evaluate the given integral. (b) If you have a CAS, use it to evaluate the integral, and then confirm that the result is equivalent to the one that you found in part (a). ■

**1.** $\displaystyle\int \frac{4x}{3x-1}\,dx$

**2.** $\displaystyle\int \frac{x}{(4-5x)^2}\,dx$

**3.** $\displaystyle\int \frac{1}{x(2x+5)}\,dx$

**4.** $\displaystyle\int \frac{1}{x^2(1-5x)}\,dx$

**5.** $\displaystyle\int x\sqrt{2x+3}\,dx$

**6.** $\displaystyle\int \frac{x}{\sqrt{2-x}}\,dx$

**7.** $\displaystyle\int \frac{1}{x\sqrt{4-3x}}\,dx$

**8.** $\displaystyle\int \frac{1}{x\sqrt{3x-4}}\,dx$

**9.** $\displaystyle\int \frac{1}{16-x^2}\,dx$

**10.** $\displaystyle\int \frac{1}{x^2-9}\,dx$

**11.** $\displaystyle\int \sqrt{x^2-3}\,dx$

**12.** $\displaystyle\int \frac{\sqrt{x^2-5}}{x^2}\,dx$

**13.** $\displaystyle\int \frac{x^2}{\sqrt{x^2+4}}\,dx$

**14.** $\displaystyle\int \frac{1}{x^2\sqrt{x^2-2}}\,dx$

**15.** $\displaystyle\int \sqrt{9-x^2}\,dx$

**16.** $\displaystyle\int \frac{\sqrt{4-x^2}}{x^2}\,dx$

**17.** $\displaystyle\int \frac{\sqrt{4-x^2}}{x}\,dx$

**18.** $\displaystyle\int \frac{1}{x\sqrt{6x-x^2}}\,dx$

**19.** $\displaystyle\int \sin 3x \sin 4x\,dx$

**20.** $\displaystyle\int \sin 2x \cos 5x\,dx$

**21.** $\displaystyle\int x^3 \ln x\,dx$

**22.** $\displaystyle\int \frac{\ln x}{\sqrt{x^3}}\,dx$

**23.** $\displaystyle\int e^{-2x} \sin 3x\,dx$

**24.** $\displaystyle\int e^{x} \cos 2x\,dx$

C **25–36** (a) Make the indicated $u$-substitution, and then use the Endpaper Integral Table to evaluate the integral. (b) If you have a CAS, use it to evaluate the integral, and then confirm that the result is equivalent to the one that you found in part (a). ■

**25.** $\displaystyle\int \frac{e^{4x}}{(4-3e^{2x})^2}\,dx,\ u = e^{2x}$

**26.** $\displaystyle\int \frac{\sin 2x}{(\cos 2x)(3-\cos 2x)}\,dx,\ u = \cos 2x$

**27.** $\displaystyle\int \frac{1}{\sqrt{x}(9x+4)}\,dx,\ u = 3\sqrt{x}$

**28.** $\displaystyle\int \frac{\cos 4x}{9+\sin^2 4x}\,dx,\ u = \sin 4x$

**29.** $\displaystyle\int \frac{1}{\sqrt{4x^2-9}}\,dx,\ u = 2x$

**81.** $y = 2x^2,\ 0 \le x \le 2$ **82.** $y = 3\ln x,\ 1 \le x \le 3$

**83–84** Use any method to find the area of the surface generated by revolving the curve about the $x$-axis.

**83.** $y = \sin x,\ 0 \le x \le \pi$ **84.** $y = 1/x,\ 1 \le x \le 4$

C **85–86** Information is given about the motion of a particle moving along a coordinate line.

(a) Use a CAS to find the position function of the particle for $t \ge 0$.

(b) Graph the position versus time curve.

**85.** $v(t) = 20\cos^6 t\sin^3 t,\ s(0) = 2$

**86.** $a(t) = e^{-t}\sin 2t\sin 4t,\ v(0) = 0,\ s(0) = 10$

**FOCUS ON CONCEPTS**

**87.** (a) Use the substitution $u = \tan(x/2)$ to show that

$$\int \sec x\,dx = \ln\left|\frac{1+\tan(x/2)}{1-\tan(x/2)}\right| + C$$

and confirm that this is consistent with Formula (22) of Section 7.3.

(b) Use the result in part (a) to show that

$$\int \sec x\,dx = \ln\left|\tan\left(\frac{\pi}{4}+\frac{x}{2}\right)\right| + C$$

**88.** Use the substitution $u = \tan(x/2)$ to show that

$$\int \csc x\,dx = \frac{1}{2}\ln\left[\frac{1-\cos x}{1+\cos x}\right] + C$$

and confirm that this is consistent with the result in Exercise 65(a) of Section 7.3.

**89.** Find a substitution that can be used to integrate rational functions of $\sinh x$ and $\cosh x$ and use your substitution to evaluate

$$\int \frac{dx}{2\cosh x+\sinh x}$$

without expressing the integrand in terms of $e^x$ and $e^{-x}$.

C **90–93** Some integrals that can be evaluated by hand cannot be evaluated by all computer algebra systems. Evaluate the integral by hand, and determine if it can be evaluated on your CAS.

**90.** $\displaystyle\int \frac{x^3}{\sqrt{1-x^8}}dx$

**91.** $\displaystyle\int (\cos^{32}x\sin^{30}x - \cos^{30}x\sin^{32}x)\,dx$

**92.** $\displaystyle\int \sqrt{x-\sqrt{x^2-4}}\,dx$ [*Hint:* $\frac{1}{2}(\sqrt{x+2}-\sqrt{x-2})^2 = ?$]

**93.** $\displaystyle\int \frac{1}{x^{10}+x}\,dx$

[*Hint:* Rewrite the denominator as $x^{10}(1+x^{-9})$.]

C **94.** Let

$$f(x)=\frac{-2x^5+26x^4+15x^3+6x^2+20x+43}{x^6-x^5-18x^4-2x^3-39x^2-x-20}$$

(a) Use a CAS to factor the denominator, and then write down the form of the partial fraction decomposition. You need not find the values of the constants.
(b) Check your answer in part (a) by using the CAS to find the partial fraction decomposition of $f$.
(c) Integrate $f$ by hand, and then check your answer by integrating with the CAS.

# 7.7 NUMERICAL INTEGRATION; SIMPSON'S RULE

*If it is necessary to evaluate a definite integral of a function for which an antiderivative cannot be found, then one must settle for some kind of numerical approximation of the integral. In Section 5.4 we considered three such approximations in the context of areas—left endpoint approximation, right endpoint approximation, and midpoint approximation. In this section we will extend those methods to general definite integrals, and we will develop some new methods that often provide more accuracy with less computation. We will also discuss the errors that arise in integral approximations.*

## A REVIEW OF RIEMANN SUM APPROXIMATIONS

Recall from Section 5.5 that the definite integral of a continuous function $f$ over an interval $[a,b]$ may be computed as

$$\int_a^b f(x)\,dx=\lim_{\max\Delta x_k\to 0}\sum_{k=1}^{n}f(x_k^*)\Delta x_k$$

where the sum that appears on the right side is called a Riemann sum. In this formula, $\Delta x_k$ is the width of the $k$th subinterval of a partition $a=x_0<x_1<x_2<\cdots<x_n=b$ of $[a,b]$ into $n$ subintervals, and $x_k^*$ denotes an arbitrary point in the $k$th subinterval. If we take all subintervals of the same width, so that $\Delta x_k=(b-a)/n$, then as $n$ increases the Riemann sum will eventually be a good approximation to the definite integral. We denote this by writing

$$\int_a^b f(x)\,dx\approx\left(\frac{b-a}{n}\right)[f(x_1^*)+f(x_2^*)+\cdots+f(x_n^*)] \tag{1}$$

If we denote the values of $f$ at the endpoints of the subintervals by

$$y_0=f(a),\quad y_1=f(x_1),\quad y_2=f(x_2),\ldots,y_{n-1}=f(x_{n-1}),\quad y_n=f(x_n)$$

and the values of $f$ at the midpoints of the subintervals by

$$y_{m_1},y_{m_2},\ldots,y_{m_n}$$

then it follows from (1) that the left endpoint, right endpoint, and midpoint approximations discussed in Section 5.4 can be expressed as shown in Table 7.7.1. Although we originally

**Table 7.7.1**

| LEFT ENDPOINT APPROXIMATION | RIGHT ENDPOINT APPROXIMATION | MIDPOINT APPROXIMATION |
|---|---|---|
| $\int_a^b f(x)\,dx \approx \left(\frac{b-a}{n}\right)[y_0 + y_1 + \cdots + y_{n-1}]$ | $\int_a^b f(x)\,dx \approx \left(\frac{b-a}{n}\right)[y_1 + y_2 + \cdots + y_n]$ | $\int_a^b f(x)\,dx \approx \left(\frac{b-a}{n}\right)[y_{m_1} + y_{m_2} + \cdots + y_{m_n}]$ |
|  |  |  |

obtained these results for nonnegative functions in the context of approximating areas, they are applicable to any function that is continuous on $[a, b]$.

## TRAPEZOIDAL APPROXIMATION

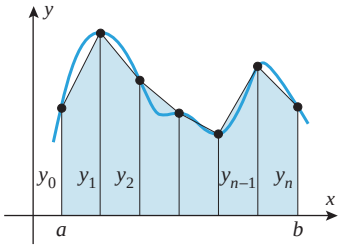
It will be convenient in this section to denote the left endpoint, right endpoint, and midpoint approximations with $n$ subintervals by $L_n$, $R_n$, and $M_n$, respectively. Of the three approximations, the midpoint approximation is most widely used in applications. If we take the average of $L_n$ and $R_n$, then we obtain another important approximation denoted by

$$T_n = \tfrac{1}{2}(L_n + R_n)$$

called the ***trapezoidal approximation***:

***Trapezoidal Approximation***

$$\int_a^b f(x)\,dx \approx T_n = \left(\frac{b-a}{2n}\right)[y_0 + 2y_1 + \cdots + 2y_{n-1} + y_n] \tag{2}$$



▲ **Figure 7.7.1**

The name "trapezoidal approximation" results from the fact that in the case where $f$ is nonnegative on the interval of integration, the approximation $T_n$ is the sum of the trapezoidal areas shown in Figure 7.7.1 (see Exercise 51).

**► Example 1** In Table 7.7.2 we have approximated

$$\ln 2 = \int_1^2 \frac{1}{x}\,dx$$

using the midpoint approximation and the trapezoidal approximation.* In each case we used $n = 10$ subdivisions of the interval $[1, 2]$, so that

$$\underbrace{\frac{b-a}{n} = \frac{2-1}{10} = 0.1}_{\text{Midpoint}} \quad \text{and} \quad \underbrace{\frac{b-a}{2n} = \frac{2-1}{20} = 0.05}_{\text{Trapezoidal}} \quad \blacktriangleleft$$

*Throughout this section we will show numerical values to nine places to the right of the decimal point. If your calculating utility does not show this many places, then you will need to make the appropriate adjustments. What is important here is that you understand the principles being discussed.

**Table 7.7.2**

MIDPOINT AND TRAPEZOIDAL APPROXIMATIONS FOR $\int_1^2 \frac{1}{x}\,dx$

| MIDPOINT APPROXIMATION | | | TRAPEZOIDAL APPROXIMATION | | | | |
|---|---|---|---|---|---|---|---|
| $i$ | MIDPOINT $m_i$ | $y_{m_i} = f(m_i) = 1/m_i$ | $i$ | ENDPOINT $x_i$ | $y_i = f(x_i) = 1/x_i$ | MULTIPLIER $w_i$ | $w_i y_i$ |

## COMPARISON OF THE MIDPOINT AND TRAPEZOIDAL APPROXIMATIONS

We define the ***errors*** in the midpoint and trapezoidal approximations to be

$$E_M = \int_a^b f(x)\,dx - M_n \quad \text{and} \quad E_T = \int_a^b f(x)\,dx - T_n \tag{3–4}$$

respectively, and we define $|E_M|$ and $|E_T|$ to be the ***absolute errors*** in these approximations. The absolute errors are nonnegative and do not distinguish between underestimates and overestimates.

By rewriting (3) and (4) in the form

$$\int_a^b f(x)\,dx = \text{approximation} + \text{error}$$

we see that positive values of $E_M$ and $E_T$ correspond to underestimates and negative values to overestimates.

▶ **Example 2** The value of $\ln 2$ to nine decimal places is

$$\ln 2 = \int_1^2 \frac{1}{x}\,dx \approx 0.693147181 \tag{5}$$

so we see from Tables 7.7.2 and 7.7.3 that the absolute errors in approximating $\ln 2$ by $M_{10}$ and $T_{10}$ are

$$|E_M| = |\ln 2 - M_{10}| \approx 0.000311821$$
$$|E_T| = |\ln 2 - T_{10}| \approx 0.000624222$$

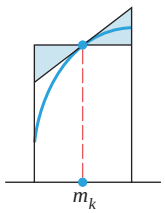
Thus, the midpoint approximation is more accurate than the trapezoidal approximation in this case. ◀

**Table 7.7.3**

| $\ln 2$ (NINE DECIMAL PLACES) | APPROXIMATION | ERROR |
|---|---|---|
| 0.693147181 | $M_{10} \approx 0.692835360$ | $E_M = \ln 2 - M_{10} \approx 0.000311821$ |
| 0.693147181 | $T_{10} \approx 0.693771403$ | $E_T = \ln 2 - T_{10} \approx -0.000624222$ |

It is not accidental in Example 2 that the midpoint approximation of $\ln 2$ was more accurate than the trapezoidal approximation. To see why this is so, we first need to look at the midpoint approximation from another point of view. To simplify our explanation, we will assume that $f$ is nonnegative on $[a, b]$, though the conclusions we reach will be true without this assumption.

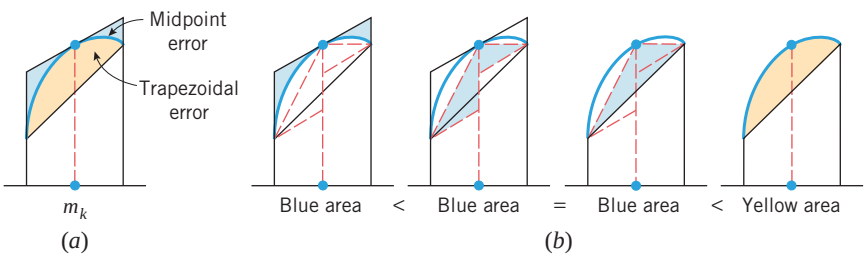
If $f$ is a differentiable function, then the midpoint approximation is sometimes called the ***tangent line approximation*** because for each subinterval of $[a, b]$ the area of the rectangle used in the midpoint approximation is equal to the area of the trapezoid whose upper boundary is the tangent line to $y = f(x)$ at the midpoint of the subinterval (Figure 7.7.2). The equality of these areas follows from the fact that the shaded areas in the figure are congruent. We will now show how this point of view about midpoint approximations can be used to establish useful criteria for determining which of $M_n$ or $T_n$ produces the better approximation of a given integral.



▲ **Figure 7.7.2**

In Figure 7.7.3*a* we have isolated a subinterval of $[a, b]$ on which the graph of a function $f$ is concave down, and we have shaded the areas that represent the errors in the midpoint and trapezoidal approximations over the subinterval. In Figure 7.7.3*b* we show a succession of four illustrations which make it evident that the error from the midpoint approximation is less than that from the trapezoidal approximation. If the graph of $f$ were concave up, analogous figures would lead to the same conclusion. (This argument, due to Frank Buck, appeared in *The College Mathematics Journal*, Vol. 16, No. 1, 1985.)

Justify the conclusions in each step of Figure 7.7.3*b*.



▲ **Figure 7.7.3**

Figure 7.7.3*a* also suggests that on a subinterval where the graph is concave down, the midpoint approximation is larger than the value of the integral and the trapezoidal approximation is smaller. On an interval where the graph is concave up it is the other way around. In summary, we have the following result, which we state without formal proof:

**7.7.1 THEOREM** *Let $f$ be continuous on $[a, b]$, and let $|E_M|$ and $|E_T|$ be the absolute errors that result from the midpoint and trapezoidal approximations of $\int_a^b f(x)\,dx$ using $n$ subintervals.*

(*a*) *If the graph of $f$ is either concave up or concave down on $(a, b)$, then $|E_M| < |E_T|$, that is, the absolute error from the midpoint approximation is less than that from the trapezoidal approximation.*

(*b*) *If the graph of $f$ is concave down on $(a, b)$, then*

$$T_n < \int_a^b f(x)\,dx < M_n$$

(*c*) *If the graph of $f$ is concave up on $(a, b)$, then*

$$M_n < \int_a^b f(x)\,dx < T_n$$

▶ **Example 3** Since the graph of $f(x) = 1/x$ is continuous on the interval $[1, 2]$ and concave up on the interval $(1, 2)$, it follows from part $(a)$ of Theorem 7.7.1 that $M_n$ will always provide a better approximation than $T_n$ for

$$\int_1^2 \frac{1}{x}\,dx = \ln 2$$

Moreover, if follows from part $(c)$ of Theorem 7.7.1 that $M_n < \ln 2 < T_n$ for every positive integer $n$. Note that this is consistent with our computations in Example 2. ◀

**WARNING**

Do not conclude that the midpoint approximation is always better than the trapezoidal approximation; the trapezoidal approximation may be better if the function changes concavity on the interval of integration.

▶ **Example 4** The midpoint and trapezoidal approximations can be used to approximate $\sin 1$ by using the integral

$$\sin 1 = \int_0^1 \cos x\,dx$$

Since $f(x) = \cos x$ is continuous on $[0, 1]$ and concave down on $(0, 1)$, it follows from parts $(a)$ and $(b)$ of Theorem 7.7.1 that the absolute error in $M_n$ will be less than that in $T_n$, and that $T_n < \sin 1 < M_n$ for every positive integer $n$. This is consistent with the results in Table 7.7.4 for $n = 5$ (intermediate computations are omitted). ◀

**Table 7.7.4**

| sin 1 (NINE DECIMAL PLACES) | APPROXIMATION | ERROR |
|---|---|---|
| 0.841470985 | $M_5 \approx 0.842875074$ | $E_M = \sin 1 - M_5 \approx -0.001404089$ |
| 0.841470985 | $T_5 \approx 0.838664210$ | $E_T = \sin 1 - T_5 \approx 0.002806775$ |

▶ **Example 5** Table 7.7.5 shows approximations for $\sin 3 = \int_0^3 \cos x\,dx$ using the midpoint and trapezoidal approximations with $n = 10$ subdivisions of the interval $[0, 3]$. Note that $|E_M| < |E_T|$ and $T_{10} < \sin 3 < M_{10}$, although these results are not guaranteed by Theorem 7.7.1 since $f(x) = \cos x$ changes concavity on the interval $[0, 3]$. ◀

**Table 7.7.5**

| sin 3 (NINE DECIMAL PLACES) | APPROXIMATION | ERROR |
|---|---|---|
| 0.141120008 | $M_{10} \approx 0.141650601$ | $E_M = \sin 3 - M_{10} \approx -0.000530592$ |
| 0.141120008 | $T_{10} \approx 0.140060017$ | $E_T = \sin 3 - T_{10} \approx 0.001059991$ |

## SIMPSON'S RULE

When the left and right endpoint approximations are averaged to produce the trapezoidal approximation, a better approximation often results. We now see how a weighted average of the midpoint and trapezoidal approximations can yield an even better approximation.

The numerical evidence in Tables 7.7.3, 7.7.4, and 7.7.5 reveals that $E_T \approx -2E_M$, so that $2E_M + E_T \approx 0$ in these instances. This suggests that

$$\begin{aligned} 3\int_a^b f(x)\,dx &= 2\int_a^b f(x)\,dx + \int_a^b f(x)\,dx \\ &= 2(M_k + E_M) + (T_k + E_T) \\ &= (2M_k + T_k) + (2E_M + E_T) \\ &\approx 2M_k + T_k \end{aligned}$$

This gives

$$\int_a^b f(x)\,dx \approx \tfrac{1}{3}(2M_k + T_k) \tag{6}$$

**WARNING**

Note that in (7) the subscript $n$ in $S_n$ is always *even* since it is twice the value of the subscripts for the corresponding midpoint and trapezoidal approximations. For example,

$$S_{10} = \tfrac{1}{3}(2M_5 + T_5)$$

and

$$S_{20} = \tfrac{1}{3}(2M_{10} + T_{10})$$

The midpoint approximation $M_k$ in (6) requires the evaluation of $f$ at $k$ points in the interval $[a, b]$, and the trapezoidal approximation $T_k$ in (6) requires the evaluation of $f$ at $k + 1$ points in $[a, b]$. Thus, $\frac{1}{3}(2M_k + T_k)$ uses $2k + 1$ values of $f$, taken at equally spaced points in the interval $[a, b]$. These points are obtained by partitioning $[a, b]$ into $2k$ equal subintervals indicated by the left endpoints, right endpoints, and midpoints used in $T_k$ and $M_k$, respectively. Setting $n = 2k$, we use $S_n$ to denote the weighted average of $M_k$ and $T_k$ in (6). That is,

$$S_n = S_{2k} = \tfrac{1}{3}(2M_k + T_k) \quad \text{or} \quad S_n = \tfrac{1}{3}(2M_{n/2} + T_{n/2}) \tag{7}$$

Table 7.7.6 displays the approximations $S_n$ corresponding to the data in Tables 7.7.3 to 7.7.5.

**Table 7.7.6**

| FUNCTION VALUE (NINE DECIMAL PLACES) | APPROXIMATION | ERROR |
|---|---|---|
| $\ln 2 \approx 0.693147181$ | $\int_1^2 (1/x)\,dx \approx S_{20} = \frac{1}{3}(2M_{10} + T_{10}) \approx 0.693147375$ | $-0.000000194$ |
| $\sin 1 \approx 0.841470985$ | $\int_0^1 \cos x\,dx \approx S_{10} = \frac{1}{3}(2M_5 + T_5) \approx 0.841471453$ | $-0.000000468$ |
| $\sin 3 \approx 0.141120008$ | $\int_0^3 \cos x\,dx \approx S_{20} = \frac{1}{3}(2M_{10} + T_{10}) \approx 0.141120406$ | $-0.000000398$ |

Using the midpoint approximation formula in Table 7.7.1 and Formula (2) for the trapezoidal approximation, we can derive a similar formula for $S_n$. We start by partitioning the interval $[a, b]$ into an *even* number of equal subintervals. If $n$ is the number of subintervals, then each subinterval has length $(b - a)/n$. Label the endpoints of these subintervals successively by $a = x_0, x_1, x_2, \ldots, x_n = b$. Then $x_0, x_2, x_4, \ldots, x_n$ define a partition of $[a, b]$ into $n/2$ equal intervals, each of length $2(b - a)/n$, and the midpoints of these subintervals are $x_1, x_3, x_5, \ldots, x_{n-1}$, respectively, as illustrated in Figure 7.7.4. Using $y_i = f(x_i)$, we have

$$\begin{aligned} 2M_{n/2} &= 2\left(\frac{2(b-a)}{n}\right)[y_1 + y_3 + \cdots + y_{n-1}] \\ &= \left(\frac{b-a}{n}\right)[4y_1 + 4y_3 + \cdots + 4y_{n-1}] \end{aligned}$$

Noting that $(b - a)/[2(n/2)] = (b - a)/n$, we can express $T_{n/2}$ as

$$T_{n/2} = \left(\frac{b-a}{n}\right)[y_0 + 2y_2 + 2y_4 + \cdots + 2y_{n-2} + y_n]$$

Thus, $S_n = \frac{1}{3}(2M_{n/2} + T_{n/2})$ can be expressed as

$$S_n = \frac{1}{3}\left(\frac{b-a}{n}\right)[y_0 + 4y_1 + 2y_2 + 4y_3 + 2y_4 + \cdots + 2y_{n-2} + 4y_{n-1} + y_n] \tag{8}$$

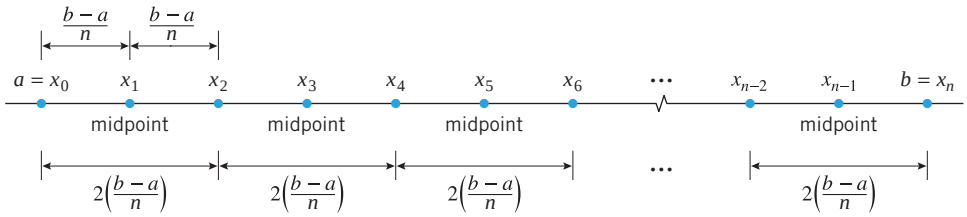
The approximation

$$\int_a^b f(x)\,dx \approx S_n \tag{9}$$

with $S_n$ as given in (8) is known as ***Simpson's rule***. We denote the error in this approximation by

$$E_S = \int_a^b f(x)\,dx - S_n \tag{10}$$

As before, the absolute error in the approximation (9) is given by $|E_S|$.



▶ Figure 7.7.4

▶ **Example 6** In Table 7.7.7 we have used Simpson's rule with $n = 10$ subintervals to obtain the approximation

$$\ln 2 = \int_1^2 \frac{1}{x}\,dx \approx S_{10} = 0.693150231$$

For this approximation,

$$\frac{1}{3}\left(\frac{b-a}{n}\right) = \frac{1}{3}\left(\frac{2-1}{10}\right) = \frac{1}{30}$$

**Table 7.7.7**

AN APPROXIMATION TO $\ln 2$ USING SIMPSON'S RULE

| $i$ | ENDPOINT $x_i$ | $y_i = f(x_i) = 1/x_i$ | MULTIPLIER $w_i$ | $w_i y_i$ |
|---|---|---|---|---|
| 0 | 1.0 | 1.000000000 | 1 | 1.000000000 |

| 9 | 1.9 | 0.526315789 | 4 | 2.105263158 |
| 10 | 2.0 | 0.500000000 | 1 | 0.500000000 |
| | | | | 20.794506921 |

$$\int_1^2 \frac{1}{x}\,dx \approx \left(\tfrac{1}{30}\right)(20.794506921) \approx 0.693150231$$

**Thomas Simpson (1710–1761)** English mathematician. Simpson was the son of a weaver. He was trained to follow in his father's footsteps and had little formal education in his early life. His interest in science and mathematics was aroused in 1724, when he witnessed an eclipse of the Sun and received two books from a peddler, one on astrology and the other on arithmetic. Simpson quickly absorbed their contents and soon became a successful local fortune teller. His improved financial situation enabled him to give up weaving and marry his landlady. Then in 1733 some mysterious "unfortunate incident" forced him to move. He settled in Derby, where he taught in an evening school and worked at weaving during the day. In 1736 he moved to London and published his first mathematical work in a periodical called the *Ladies' Diary* (of which he later became the editor). In 1737 he published a successful calculus textbook that enabled him to give up weaving completely and concentrate on textbook writing and teaching. His fortunes improved further in 1740 when one Robert Heath accused him of plagiarism. The publicity was marvelous, and Simpson proceeded to dash off a succession of best-selling textbooks: *Algebra* (ten editions plus translations), *Geometry* (twelve editions plus translations), *Trigonometry* (five editions plus translations), and numerous others. It is interesting to note that Simpson did not discover the rule that bears his name—it was a well-known result by Simpson's time.

[*Image: http://www-history.mcs.st-and.ac.uk/Posters/820.html*]

Although $S_{10}$ is a weighted average of $M_5$ and $T_5$, it makes sense to compare $S_{10}$ to $M_{10}$ and $T_{10}$, since the sums for these three approximations involve the same number of terms. Using the values for $M_{10}$ and $T_{10}$ from Example 2 and the value for $S_{10}$ in Table 7.7.7, we have

$$|E_M| = |\ln 2 - M_{10}| \approx |0.693147181 - 0.692835360| = 0.000311821$$

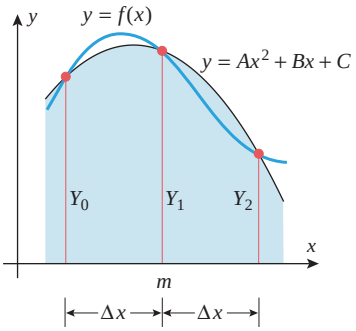
$$|E_T| = |\ln 2 - T_{10}| \approx |0.693147181 - 0.693771403| = 0.000624222$$

$$|E_S| = |\ln 2 - S_{10}| \approx |0.693147181 - 0.693150231| = 0.000003050$$

Comparing these absolute errors, it is clear that $S_{10}$ is a much more accurate approximation of $\ln 2$ than either $M_{10}$ or $T_{10}$. ◀

## GEOMETRIC INTERPRETATION OF SIMPSON'S RULE

The midpoint (or tangent line) approximation and the trapezoidal approximation for a definite integral are based on approximating a segment of the curve $y = f(x)$ by line segments. Intuition suggests that we might improve on these approximations using parabolic arcs rather than line segments, thereby accounting for concavity of the curve $y = f(x)$ more closely.



▲ Figure 7.7.5

At the heart of this idea is a formula, sometimes called the ***one-third rule***. The one-third rule expresses a definite integral of a quadratic function $g(x) = Ax^2 + Bx + C$ in terms of the values $Y_0$, $Y_1$, and $Y_2$ of $g$ at the left endpoint, midpoint, and right endpoint, respectively, of the interval of integration $[m - \Delta x, m + \Delta x]$ (see Figure 7.7.5):

$$\int_{m-\Delta x}^{m+\Delta x} (Ax^2 + Bx + C)\,dx = \frac{\Delta x}{3}[Y_0 + 4Y_1 + Y_2] \tag{11}$$

Verification of the one-third rule is left for the reader (Exercise 53). By applying the one-third rule to subintervals $[x_{2k-2}, x_{2k}]$, $k = 1, \ldots, n/2$, one arrives at Formula (8) for Simpson's rule (Exercise 54). Thus, Simpson's rule corresponds to the integral of a piecewise-quadratic approximation to $f(x)$.

## ERROR BOUNDS

With all the methods studied in this section, there are two sources of error: the *intrinsic* or *truncation error* due to the approximation formula, and the *roundoff error* introduced in the calculations. In general, increasing $n$ reduces the truncation error but increases the roundoff error, since more computations are required for larger $n$. In practical applications, it is important to know how large $n$ must be taken to ensure that a specified degree of accuracy is obtained. The analysis of roundoff error is complicated and will not be considered here. However, the following theorems, which are proved in books on numerical analysis, provide upper bounds on the truncation errors in the midpoint, trapezoidal, and Simpson's rule approximations.

**7.7.2 THEOREM** (***Midpoint and Trapezoidal Error Bounds***) *If $f''$ is continuous on $[a, b]$ and if $K_2$ is the maximum value of $|f''(x)|$ on $[a, b]$, then*

$$(a)\ |E_M| = \left|\int_a^b f(x)\,dx - M_n\right| \le \frac{(b-a)^3 K_2}{24n^2} \tag{12}$$

$$(b)\ |E_T| = \left|\int_a^b f(x)\,dx - T_n\right| \le \frac{(b-a)^3 K_2}{12n^2} \tag{13}$$

**7.7.3 THEOREM** (*Simpson Error Bound*) *If $f^{(4)}$ is continuous on $[a, b]$ and if $K_4$ is the maximum value of $|f^{(4)}(x)|$ on $[a, b]$, then*

$$|E_S| = \left| \int_a^b f(x)\,dx - S_n \right| \le \frac{(b-a)^5 K_4}{180n^4} \tag{14}$$

▶ **Example 7** Find an upper bound on the absolute error that results from approximating

$$\ln 2 = \int_1^2 \frac{1}{x}\,dx$$

using (a) the midpoint approximation $M_{10}$, (b) the trapezoidal approximation $T_{10}$, and (c) Simpson's rule $S_{10}$, each with $n = 10$ subintervals.

***Solution.*** We will apply Formulas (12), (13), and (14) with

$$f(x) = \frac{1}{x}, \quad a = 1, \quad b = 2, \quad \text{and} \quad n = 10$$

We have

$$f'(x) = -\frac{1}{x^2}, \quad f''(x) = \frac{2}{x^3}, \quad f'''(x) = -\frac{6}{x^4}, \quad f^{(4)}(x) = \frac{24}{x^5}$$

Thus,

$$|f''(x)| = \left|\frac{2}{x^3}\right| = \frac{2}{x^3}, \quad |f^{(4)}(x)| = \left|\frac{24}{x^5}\right| = \frac{24}{x^5}$$

where we have dropped the absolute values because $f''(x)$ and $f^{(4)}(x)$ have positive values for $1 \le x \le 2$. Since $|f''(x)|$ and $|f^4(x)|$ are continuous and decreasing on $[1, 2]$, both functions have their maximum values at $x = 1$; for $|f''(x)|$ this maximum value is 2 and for $|f^4(x)|$ the maximum value is 24. Thus we can take $K_2 = 2$ in (12) and (13), and $K_4 = 24$ in (14). This yields

$$|E_M| \le \frac{(b-a)^3 K_2}{24n^2} = \frac{1^3 \cdot 2}{24 \cdot 10^2} \approx 0.000833333$$

$$|E_T| \le \frac{(b-a)^3 K_2}{12n^2} = \frac{1^3 \cdot 2}{12 \cdot 10^2} \approx 0.001666667$$

$$|E_S| \le \frac{(b-a)^5 K_4}{180n^4} = \frac{1^5 \cdot 24}{180 \cdot 10^4} \approx 0.000013333 \quad \blacktriangleleft$$

Note that the upper bounds calculated in Example 7 are consistent with the values $|E_M|$, $|E_T|$, and $|E_S|$ calculated in Example 6 but are considerably greater than those values. It is quite common that the upper bounds on the absolute errors given in Theorems 7.7.2 and 7.7.3 substantially exceed the actual absolute errors. However, that does not diminish the utility of these bounds.

▶ **Example 8** How many subintervals should be used in approximating

$$\ln 2 = \int_1^2 \frac{1}{x}\,dx$$

by Simpson's rule for five decimal-place accuracy?

***Solution.*** To obtain five decimal-place accuracy, we must choose the number of subintervals so that

$$|E_S| \le 0.000005 = 5 \times 10^{-6}$$

From (14), this can be achieved by taking $n$ in Simpson's rule to satisfy

$$\frac{(b-a)^5 K_4}{180n^4} \le 5 \times 10^{-6}$$

Taking $a = 1$, $b = 2$, and $K_4 = 24$ (found in Example 7) in this inequality yields

$$\frac{1^5 \cdot 24}{180 \cdot n^4} \le 5 \times 10^{-6}$$

which, on taking reciprocals, can be rewritten as

$$n^4 \ge \frac{2 \times 10^6}{75} = \frac{8 \times 10^4}{3}$$

Thus,

$$n \ge \frac{20}{\sqrt[4]{6}} \approx 12.779$$

Since $n$ must be an even integer, the smallest value of $n$ that satisfies this requirement is $n = 14$. Thus, the approximation $S_{14}$ using 14 subintervals will produce five decimal-place accuracy. ◀

**REMARK** In cases where it is difficult to find the values of $K_2$ and $K_4$ in Formulas (12), (13), and (14), these constants may be replaced by any larger constants. For example, suppose that a constant $K$ can be easily found with the certainty that $|f''(x)| < K$ on the interval. Then $K_2 \le K$ and

$$|E_T| \le \frac{(b-a)^3 K_2}{12n^2} \le \frac{(b-a)^3 K}{12n^2} \tag{15}$$

so the right side of (15) is also an upper bound on the value of $|E_T|$. Using $K$, however, will likely increase the computed value of $n$ needed for a given error tolerance. Many applications involve the resolution of competing practical issues, illustrated here through the trade-off between the convenience of finding a crude bound for $|f''(x)|$ versus the efficiency of using the smallest possible $n$ for a desired accuracy.

▶ **Example 9** How many subintervals should be used in approximating

$$\int_0^1 \cos(x^2)\,dx$$

by the midpoint approximation for three decimal-place accuracy?

***Solution.*** To obtain three decimal-place accuracy, we must choose $n$ so that

$$|E_M| \le 0.0005 = 5 \times 10^{-4} \tag{16}$$

From (12) with $f(x) = \cos(x^2)$, $a = 0$, and $b = 1$, an upper bound on $|E_M|$ is given by

$$|E_M| \le \frac{K_2}{24n^2} \tag{17}$$

where $|K_2|$ is the maximum value of $|f''(x)|$ on the interval $[0, 1]$. However,

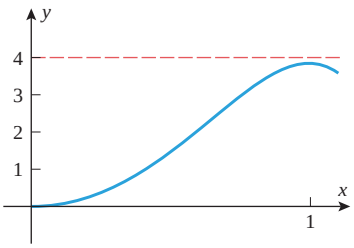
$$f'(x) = -2x\sin(x^2)$$
$$f''(x) = -4x^2\cos(x^2) - 2\sin(x^2) = -[4x^2\cos(x^2) + 2\sin(x^2)]$$

so that

$$|f''(x)| = |4x^2\cos(x^2) + 2\sin(x^2)| \tag{18}$$

It would be tedious to look for the maximum value of this function on the interval $[0, 1]$. For $x$ in $[0, 1]$, it is easy to see that each of the expressions $x^2$, $\cos(x^2)$, and $\sin(x^2)$ is bounded in absolute value by 1, so $|4x^2\cos(x^2) + 2\sin(x^2)| \le 4 + 2 = 6$ on $[0, 1]$. We can improve on this by using a graphing utility to sketch $|f''(x)|$, as shown in Figure 7.7.6. It is evident from the graph that

$$|f''(x)| < 4 \quad \text{for} \quad 0 \le x \le 1$$



$y = |f''(x)| = |4x^2\cos(x^2) + 2\sin(x^2)|$

▲ Figure 7.7.6

Thus, it follows from (17) that

$$|E_M| \le \frac{K_2}{24n^2} < \frac{4}{24n^2} = \frac{1}{6n^2}$$

and hence we can satisfy (16) by choosing $n$ so that

$$\frac{1}{6n^2} < 5 \times 10^{-4}$$

which, on taking reciprocals, can be written as

$$n^2 > \frac{10^4}{30} \quad \text{or} \quad n > \frac{10^2}{\sqrt{30}} \approx 18.257$$

The smallest integer value of $n$ satisfying this inequality is $n = 19$. Thus, the midpoint approximation $M_{19}$ using 19 subintervals will produce three decimal-place accuracy. ◀

## A COMPARISON OF THE THREE METHODS

Of the three methods studied in this section, Simpson's rule generally produces more accurate results than the midpoint or trapezoidal approximations for the same amount of work. To make this plausible, let us express (12), (13), and (14) in terms of the subinterval width

$$\Delta x = \frac{b-a}{n}$$

We obtain

$$|E_M| \le \frac{1}{24} K_2 (b-a)(\Delta x)^2 \tag{19}$$

$$|E_T| \le \frac{1}{12} K_2 (b-a)(\Delta x)^2 \tag{20}$$

$$|E_S| \le \frac{1}{180} K_4 (b-a)(\Delta x)^4 \tag{21}$$

(verify). For Simpson's rule, the upper bound on the absolute error is proportional to $(\Delta x)^4$, whereas the upper bound on the absolute error for the midpoint and trapezoidal approximations is proportional to $(\Delta x)^2$. Thus, reducing the interval width by a factor of 10, for example, reduces the error bound by a factor of 100 for the midpoint and trapezoidal approximations but reduces the error bound by a factor of 10,000 for Simpson's rule. This suggests that, as $n$ increases, the accuracy of Simpson's rule improves much more rapidly than that of the other approximations.

As a final note, observe that if $f(x)$ is a polynomial of degree 3 or less, then we have $f^{(4)}(x) = 0$ for all $x$, so $K_4 = 0$ in (14) and consequently $|E_S| = 0$. Thus, Simpson's rule gives exact results for polynomials of degree 3 or less. Similarly, the midpoint and trapezoidal approximations give exact results for polynomials of degree 1 or less. (You should also be able to see that this is so geometrically.)

## ✔ QUICK CHECK EXERCISES 7.7 (See page 547 for answers.)

**1.** Let $T_n$ be the trapezoidal approximation for the definite integral of $f(x)$ over an interval $[a, b]$ using $n$ subintervals.
(a) Expressed in terms of $L_n$ and $R_n$ (the left and right endpoint approximations), $T_n =$ _____.
(b) Expressed in terms of the function values $y_0, y_1, \ldots, y_n$ at the endpoints of the subintervals, $T_n =$ _____.

**2.** Let $I$ denote the definite integral of $f$ over an interval $[a, b]$ with $T_n$ and $M_n$ the respective trapezoidal and midpoint approximations of $I$ for a given $n$. Assume that the graph of $f$ is concave up on the interval $[a, b]$ and order the quantities $T_n$, $M_n$, and $I$ from smallest to largest: _____ < _____ < _____.

**3.** Let $S_6$ be the Simpson's rule approximation for $\int_a^b f(x)\,dx$ using $n = 6$ subintervals.
(a) Expressed in terms of $M_3$ and $T_3$ (the midpoint and trapezoidal approximations), $S_6 =$ _____.
(b) Using the function values $y_0, y_1, y_2, \ldots, y_6$ at the endpoints of the subintervals, $S_6 =$ _____.

**4.** Assume that $f^{(4)}$ is continuous on $[0, 1]$ and that $f^{(k)}(x)$ satisfies $|f^{(k)}(x)| \le 1$ on $[0, 1]$, $k = 1, 2, 3, 4$. Find an upper bound on the absolute error that results from approximating the integral of $f$ over $[0, 1]$ using (a) the midpoint approximation $M_{10}$; (b) the trapezoidal approximation $T_{10}$; and (c) Simpson's rule $S_{10}$.

**5.** Approximate $\displaystyle\int_1^3 \frac{1}{x^2}\,dx$ using the indicated method.
(a) $M_1 =$ _____ (b) $T_1 =$ _____
(c) $S_2 =$ _____

## EXERCISE SET 7.7 C CAS

**1–6** Approximate the integral using (a) the midpoint approximation $M_{10}$, (b) the trapezoidal approximation $T_{10}$, and (c) Simpson's rule approximation $S_{20}$ using Formula (7). In each case, find the exact value of the integral and approximate the absolute error. Express your answers to at least four decimal places. ■

**1.** $\displaystyle\int_0^3 \sqrt{x+1}\,dx$ **2.** $\displaystyle\int_4^9 \frac{1}{\sqrt{x}}\,dx$ **3.** $\displaystyle\int_0^{\pi/2} \cos x\,dx$

**4.** $\displaystyle\int_0^2 \sin x\,dx$ **5.** $\displaystyle\int_1^3 e^{-2x}\,dx$ **6.** $\displaystyle\int_0^3 \frac{1}{3x+1}\,dx$

**7–12** Use inequalities (12), (13), and (14) to find upper bounds on the errors in parts (a), (b), and (c) of the indicated exercise. ■

**7.** Exercise 1 **8.** Exercise 2 **9.** Exercise 3

**10.** Exercise 4 **11.** Exercise 5 **12.** Exercise 6

**13–18** Use inequalities (12), (13), and (14) to find a number $n$ of subintervals for (a) the midpoint approximation $M_n$, (b) the trapezoidal approximation $T_n$, and (c) Simpson's rule approximation $S_n$ to ensure that the absolute error will be less than the given value. ■

**13.** Exercise 1; $5 \times 10^{-4}$ **14.** Exercise 2; $5 \times 10^{-4}$

**15.** Exercise 3; $10^{-3}$ **16.** Exercise 4; $10^{-3}$

**17.** Exercise 5; $10^{-4}$ **18.** Exercise 6; $10^{-4}$

**19–22 True–False** Determine whether the statement is true or false. Explain your answer. ■

**19.** The midpoint approximation, $M_n$, is the average of the left and right endpoint approximations, $L_n$ and $R_n$, respectively.

**20.** If $f(x)$ is concave down on the interval $(a, b)$, then the trapezoidal approximation $T_n$ underestimates $\int_a^b f(x)\,dx$.

**21.** The Simpson's rule approximation $S_{50}$ for $\int_a^b f(x)\,dx$ is a weighted average of the approximations $M_{50}$ and $T_{50}$, where $M_{50}$ is given twice the weight of $T_{50}$ in the average.

**22.** Simpson's rule approximation $S_{50}$ for $\int_a^b f(x)\,dx$ corresponds to $\int_a^b q(x)\,dx$, where the graph of $q$ is composed of 25 parabolic segments joined at points on the graph of $f$.

**23–24** Find a function $g(x)$ of the form

$$g(x) = Ax^2 + Bx + C$$

whose graph contains the points $(m - \Delta x, f(m - \Delta x))$, $(m, f(m))$, and $(m + \Delta x, f(m + \Delta x))$, for the given function $f(x)$ and the given values of $m$ and $\Delta x$. Then verify Formula (11):

$$\int_{m-\Delta x}^{m+\Delta x} g(x)\,dx = \frac{\Delta x}{3}[Y_0 + 4Y_1 + Y_2]$$

where $Y_0 = f(m - \Delta x)$, $Y_1 = f(m)$, and $Y_2 = f(m + \Delta x)$. ■

**23.** $f(x) = \dfrac{1}{x}$; $m = 3$, $\Delta x = 1$

**24.** $f(x) = \sin^2(\pi x)$; $m = \frac{1}{6}$, $\Delta x = \frac{1}{6}$

**25–30** Approximate the integral using Simpson's rule $S_{10}$ and compare your answer to that produced by a calculating utility with a numerical integration capability. Express your answers to at least four decimal places. ■

**25.** $\displaystyle\int_{-1}^{1} e^{-x^2}\,dx$ **26.** $\displaystyle\int_0^3 \frac{x}{\sqrt{2x^3+1}}\,dx$

**27.** $\displaystyle\int_{-1}^{2} x\sqrt{2+x^3}\,dx$ **28.** $\displaystyle\int_0^{\pi} \frac{x}{2+\sin x}\,dx$

**29.** $\displaystyle\int_0^1 \cos(x^2)\,dx$ **30.** $\displaystyle\int_1^2 (\ln x)^{3/2}\,dx$

**31–32** The exact value of the given integral is $\pi$ (verify). Approximate the integral using (a) the midpoint approximation $M_{10}$, (b) the trapezoidal approximation $T_{10}$, and (c) Simpson's rule approximation $S_{20}$ using Formula (7). Approximate the absolute error and express your answers to at least four decimal places. ■

**31.** $\displaystyle\int_0^2 \frac{8}{x^2+4}\,dx$ **32.** $\displaystyle\int_0^3 \frac{4}{9}\sqrt{9-x^2}\,dx$

**33.** In Example 8 we showed that taking $n = 14$ subdivisions ensures that the approximation of

$$\ln 2 = \int_1^2 \frac{1}{x}\,dx$$

by Simpson's rule is accurate to five decimal places. Confirm this by comparing the approximation of $\ln 2$ produced by Simpson's rule with $n = 14$ to the value produced directly by your calculating utility.

**34.** In each part, determine whether a trapezoidal approximation would be an underestimate or an overestimate for the definite integral.

(a) $\int_0^1 \cos(x^2)\,dx$ (b) $\int_{3/2}^2 \cos(x^2)\,dx$

**35–36** Find a value of $n$ to ensure that the absolute error in approximating the integral by the midpoint approximation will be less than $10^{-4}$. Estimate the absolute error, and express your answers to at least four decimal places. ■

**35.** $\int_0^2 x \sin x\,dx$ **36.** $\int_0^1 e^{\cos x}\,dx$

**37–38** Show that the inequalities (12) and (13) are of no value in finding an upper bound on the absolute error that results from approximating the integral using either the midpoint approximation or the trapezoidal approximation. ■

**37.** $\int_0^1 x\sqrt{x}\,dx$ **38.** $\int_0^1 \sin\sqrt{x}\,dx$

# 7.8 IMPROPER INTEGRALS

*Up to now we have focused on definite integrals with continuous integrands and finite intervals of integration. In this section we will extend the concept of a definite integral to include infinite intervals of integration and integrands that become infinite within the interval of integration.*

## IMPROPER INTEGRALS

It is assumed in the definition of the definite integral

$$\int_a^b f(x)\,dx$$

that $[a, b]$ is a finite interval and that the limit that defines the integral exists; that is, the function $f$ is integrable. We observed in Theorems 5.5.2 and 5.5.8 that continuous functions are integrable, as are bounded functions with finitely many points of discontinuity. We also observed in Theorem 5.5.8 that functions that are not bounded on the interval of integration are not integrable. Thus, for example, a function with a vertical asymptote within the interval of integration would not be integrable.

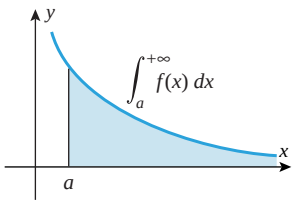
Our main objective in this section is to extend the concept of a definite integral to allow for infinite intervals of integration and integrands with vertical asymptotes within the interval of integration. We will call the vertical asymptotes ***infinite discontinuities***, and we will call

integrals with infinite intervals of integration or infinite discontinuities within the interval of integration ***improper integrals***. Here are some examples:

- Improper integrals with infinite intervals of integration:
$$\int_1^{+\infty} \frac{dx}{x^2}, \quad \int_{-\infty}^0 e^x\,dx, \quad \int_{-\infty}^{+\infty} \frac{dx}{1+x^2}$$
- Improper integrals with infinite discontinuities in the interval of integration:
$$\int_{-3}^3 \frac{dx}{x^2}, \quad \int_1^2 \frac{dx}{x-1}, \quad \int_0^{\pi} \tan x\,dx$$
- Improper integrals with infinite discontinuities and infinite intervals of integration:
$$\int_0^{+\infty} \frac{dx}{\sqrt{x}}, \quad \int_{-\infty}^{+\infty} \frac{dx}{x^2-9}, \quad \int_1^{+\infty} \sec x\,dx$$

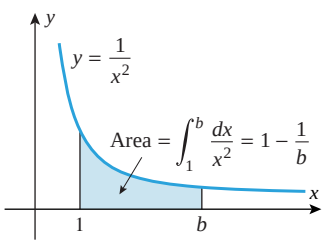
## INTEGRALS OVER INFINITE INTERVALS

To motivate a reasonable definition for improper integrals of the form
$$\int_a^{+\infty} f(x)\,dx$$
let us begin with the case where $f$ is continuous and nonnegative on $[a, +\infty)$, so we can think of the integral as the area under the curve $y = f(x)$ over the interval $[a, +\infty)$ (Figure 7.8.1). At first, you might be inclined to argue that this area is infinite because the region has infinite extent. However, such an argument would be based on vague intuition rather than precise mathematical logic, since the concept of area has only been defined over intervals of *finite extent*. Thus, before we can make any reasonable statements about the area of the region in Figure 7.8.1, we need to begin by defining what we mean by the area of this region. For that purpose, it will help to focus on a specific example.

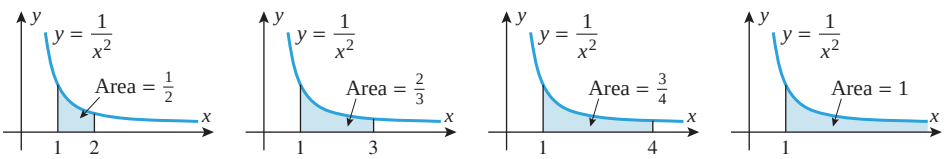


▲ Figure 7.8.1

Suppose we are interested in the area $A$ of the region that lies below the curve $y = 1/x^2$ and above the interval $[1, +\infty)$ on the $x$-axis. Instead of trying to find the entire area at once, let us begin by calculating the portion of the area that lies above a finite interval $[1, b]$, where $b > 1$ is arbitrary. That area is
$$\int_1^b \frac{dx}{x^2} = -\frac{1}{x}\Big]_1^b = 1 - \frac{1}{b}$$
(Figure 7.8.2). If we now allow $b$ to increase so that $b \to +\infty$, then the portion of the area over the interval $[1, b]$ will begin to fill out the area over the entire interval $[1, +\infty)$ (Figure 7.8.3), and hence we can reasonably define the area $A$ under $y = 1/x^2$ over the interval $[1, +\infty)$ to be
$$A = \int_1^{+\infty} \frac{dx}{x^2} = \lim_{b\to+\infty} \int_1^b \frac{dx}{x^2} = \lim_{b\to+\infty} \left(1 - \frac{1}{b}\right) = 1 \tag{1}$$
Thus, the area has a finite value of 1 and is not infinite as we first conjectured.



▲ Figure 7.8.2



▶ Figure 7.8.3

With the preceding discussion as our guide, we make the following definition (which is applicable to functions with both positive and negative values).

If $f$ is nonnegative over the interval $[a, +\infty)$, then the improper integral in Definition 7.8.1 can be interpreted to be the area under the graph of $f$ over the interval $[a, +\infty)$. If the integral converges, then the area is finite and equal to the value of the integral, and if the integral diverges, then the area is regarded to be infinite.

**7.8.1 DEFINITION** The *improper integral of f over the interval* $[a, +\infty)$ is defined to be

$$\int_a^{+\infty} f(x)\,dx = \lim_{b\to+\infty} \int_a^b f(x)\,dx$$

In the case where the limit exists, the improper integral is said to ***converge***, and the limit is defined to be the value of the integral. In the case where the limit does not exist, the improper integral is said to ***diverge***, and it is not assigned a value.

**▶ Example 1** Evaluate

$$\text{(a)} \int_1^{+\infty} \frac{dx}{x^3} \qquad \text{(b)} \int_1^{+\infty} \frac{dx}{x}$$

***Solution (a).*** Following the definition, we replace the infinite upper limit by a finite upper limit $b$, and then take the limit of the resulting integral. This yields

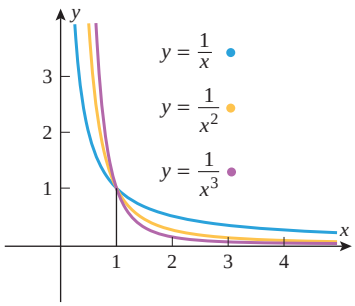
$$\int_1^{+\infty} \frac{dx}{x^3} = \lim_{b\to+\infty} \int_1^b \frac{dx}{x^3} = \lim_{b\to+\infty} \left[-\frac{1}{2x^2}\right]_1^b = \lim_{b\to+\infty} \left(\frac{1}{2} - \frac{1}{2b^2}\right) = \frac{1}{2}$$

Since the limit is finite, the integral converges and its value is $1/2$.

***Solution (b).***

$$\int_1^{+\infty} \frac{dx}{x} = \lim_{b\to+\infty} \int_1^b \frac{dx}{x} = \lim_{b\to+\infty} \left[\ln x\right]_1^b = \lim_{b\to+\infty} \ln b = +\infty$$

In this case the integral diverges and hence has no value. ◀



▲ Figure 7.8.4

Because the functions $1/x^3$, $1/x^2$, and $1/x$ are nonnegative over the interval $[1, +\infty)$, it follows from (1) and the last example that over this interval the area under $y = 1/x^3$ is $\frac{1}{2}$, the area under $y = 1/x^2$ is 1, and the area under $y = 1/x$ is infinite. However, on the surface the graphs of the three functions seem very much alike (Figure 7.8.4), and there is nothing to suggest why one of the areas should be infinite and the other two finite. One explanation is that $1/x^3$ and $1/x^2$ approach zero more rapidly than $1/x$ as $x \to +\infty$, so that the area over the interval $[1, b]$ accumulates less rapidly under the curves $y = 1/x^3$ and $y = 1/x^2$ than under $y = 1/x$ as $b \to +\infty$, and the difference is just enough that the first two areas are finite and the third is infinite.

**▶ Example 2** For what values of $p$ does the integral $\displaystyle\int_1^{+\infty} \frac{dx}{x^p}$ converge?

***Solution.*** We know from the preceding example that the integral diverges if $p = 1$, so let us assume that $p \neq 1$. In this case we have

$$\int_1^{+\infty} \frac{dx}{x^p} = \lim_{b\to+\infty} \int_1^b x^{-p}\,dx = \lim_{b\to+\infty} \frac{x^{1-p}}{1-p}\Big]_1^b = \lim_{b\to+\infty} \left[\frac{b^{1-p}}{1-p} - \frac{1}{1-p}\right]$$

If $p > 1$, then the exponent $1 - p$ is negative and $b^{1-p} \to 0$ as $b \to +\infty$; and if $p < 1$, then the exponent $1 - p$ is positive and $b^{1-p} \to +\infty$ as $b \to +\infty$. Thus, the integral converges if $p > 1$ and diverges otherwise. In the convergent case the value of the integral is

$$\int_1^{+\infty} \frac{dx}{x^p} = \left[0 - \frac{1}{1-p}\right] = \frac{1}{p-1} \quad (p > 1)$$ ◀

The following theorem summarizes this result.

**7.8.2 THEOREM**

$$\int_1^{+\infty} \frac{dx}{x^p} = \begin{cases} \dfrac{1}{p-1} & \text{if} \quad p > 1 \\ \text{diverges} & \text{if} \quad p \le 1 \end{cases}$$

**▶ Example 3** Evaluate $\displaystyle\int_0^{+\infty} (1-x)e^{-x}\,dx$.

***Solution.*** We begin by evaluating the indefinite integral using integration by parts. Setting $u = 1 - x$ and $dv = e^{-x}\,dx$ yields

$$\int (1-x)e^{-x}\,dx = -e^{-x}(1-x) - \int e^{-x}\,dx = -e^{-x} + xe^{-x} + e^{-x} + C = xe^{-x} + C$$

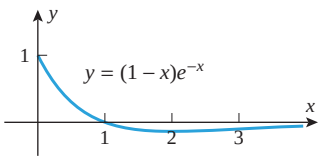
Thus,

$$\int_0^{+\infty} (1-x)e^{-x}\,dx = \lim_{b\to+\infty} \int_0^b (1-x)e^{-x}\,dx = \lim_{b\to+\infty} \left[xe^{-x}\right]_0^b = \lim_{b\to+\infty} \frac{b}{e^b}$$

The limit is an indeterminate form of type $\infty/\infty$, so we will apply L'Hôpital's rule by differentiating the numerator and denominator with respect to $b$. This yields

$$\int_0^{+\infty} (1-x)e^{-x}\,dx = \lim_{b\to+\infty} \frac{1}{e^b} = 0$$

We can interpret this to mean that the net signed area between the graph of $y = (1-x)e^{-x}$ and the interval $[0, +\infty)$ is 0 (Figure 7.8.5). ◀



The net signed area between the graph and the interval $[0, +\infty)$ is zero.

▲ **Figure 7.8.5**

If $f$ is nonnegative over the interval $(-\infty, +\infty)$, then the improper integral

$$\int_{-\infty}^{+\infty} f(x)\,dx$$

can be interpreted to be the area under the graph of $f$ over the interval $(-\infty, +\infty)$. The area is finite and equal to the value of the integral if the integral converges and is infinite if it diverges.

**7.8.3 DEFINITION** The *improper integral of f over the interval* $(-\infty, b]$ is defined to be

$$\int_{-\infty}^{b} f(x)\,dx = \lim_{a\to-\infty} \int_a^b f(x)\,dx \tag{2}$$

The integral is said to ***converge*** if the limit exists and ***diverge*** if it does not.

The *improper integral of f over the interval* $(-\infty, +\infty)$ is defined as

$$\int_{-\infty}^{+\infty} f(x)\,dx = \int_{-\infty}^{c} f(x)\,dx + \int_c^{+\infty} f(x)\,dx \tag{3}$$

where $c$ is any real number. The improper integral is said to ***converge*** if *both* terms converge and ***diverge*** if *either* term diverges.

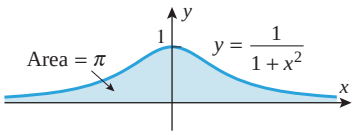
**▶ Example 4** Evaluate $\displaystyle\int_{-\infty}^{+\infty} \frac{dx}{1+x^2}$.

***Solution.*** We will evaluate the integral by choosing $c = 0$ in (3). With this value for $c$ we obtain

$$\int_0^{+\infty} \frac{dx}{1+x^2} = \lim_{b\to+\infty} \int_0^b \frac{dx}{1+x^2} = \lim_{b\to+\infty} \left[\tan^{-1} x\right]_0^b = \lim_{b\to+\infty} (\tan^{-1} b) = \frac{\pi}{2}$$

$$\int_{-\infty}^0 \frac{dx}{1+x^2} = \lim_{a\to-\infty} \int_a^0 \frac{dx}{1+x^2} = \lim_{a\to-\infty} \left[\tan^{-1} x\right]_a^0 = \lim_{a\to-\infty} (-\tan^{-1} a) = \frac{\pi}{2}$$

Although we usually choose $c = 0$ in (3), the choice does not matter because it can be proved that neither the convergence nor the value of the integral is affected by the choice of $c$.



▲ Figure 7.8.6

Thus, the integral converges and its value is

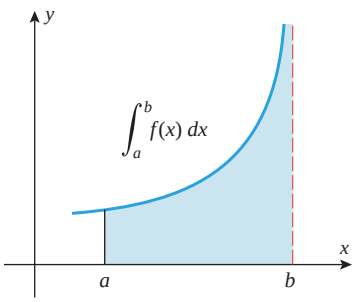
$$\int_{-\infty}^{+\infty} \frac{dx}{1+x^2} = \int_{-\infty}^{0} \frac{dx}{1+x^2} + \int_{0}^{+\infty} \frac{dx}{1+x^2} = \frac{\pi}{2} + \frac{\pi}{2} = \pi$$

Since the integrand is nonnegative on the interval $(-\infty, +\infty)$, the integral represents the area of the region shown in Figure 7.8.6. ◄

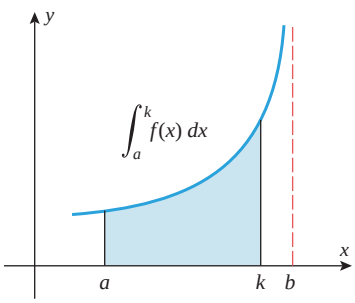
## INTEGRALS WHOSE INTEGRANDS HAVE INFINITE DISCONTINUITIES

Next we will consider improper integrals whose integrands have infinite discontinuities. We will start with the case where the interval of integration is a finite interval $[a, b]$ and the infinite discontinuity occurs at the right-hand endpoint.

To motivate an appropriate definition for such an integral let us consider the case where $f$ is nonnegative on $[a, b]$, so we can interpret the improper integral $\int_a^b f(x)\,dx$ as the area of the region in Figure 7.8.7*a*. The problem of finding the area of this region is complicated by the fact that it extends indefinitely in the positive $y$-direction. However, instead of trying to find the entire area at once, we can proceed indirectly by calculating the portion of the area over the interval $[a, k]$, where $a \le k < b$, and then letting $k$ approach $b$ to fill out the area of the entire region (Figure 7.8.7*b*). Motivated by this idea, we make the following definition.



(*a*)



(*b*)

▲ Figure 7.8.7

**7.8.4 DEFINITION** If $f$ is continuous on the interval $[a, b]$, except for an infinite discontinuity at $b$, then the ***improper integral of f over the interval [a, b]*** is defined as

$$\int_a^b f(x)\,dx = \lim_{k \to b^-} \int_a^k f(x)\,dx \tag{4}$$

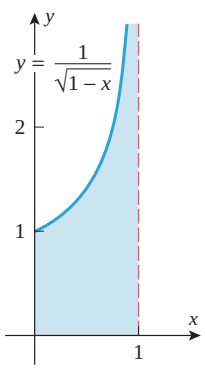
In the case where the indicated limit exists, the improper integral is said to ***converge***, and the limit is defined to be the value of the integral. In the case where the limit does not exist, the improper integral is said to ***diverge***, and it is not assigned a value.

► **Example 5** Evaluate $\displaystyle\int_0^1 \frac{dx}{\sqrt{1-x}}$.

***Solution.*** The integral is improper because the integrand approaches $+\infty$ as $x$ approaches the upper limit 1 from the left (Figure 7.8.8). From (4),

$$\int_0^1 \frac{dx}{\sqrt{1-x}} = \lim_{k \to 1^-} \int_0^k \frac{dx}{\sqrt{1-x}} = \lim_{k \to 1^-} \left[ -2\sqrt{1-x} \right]_0^k$$

$$= \lim_{k \to 1^-} \left[ -2\sqrt{1-k} + 2 \right] = 2 \quad ◄$$



▲ Figure 7.8.8

Improper integrals with an infinite discontinuity at the left-hand endpoint or inside the interval of integration are defined as follows.

**7.8.5 DEFINITION** If $f$ is continuous on the interval $[a, b]$, except for an infinite discontinuity at $a$, then the ***improper integral of f over the interval [a, b]*** is defined as

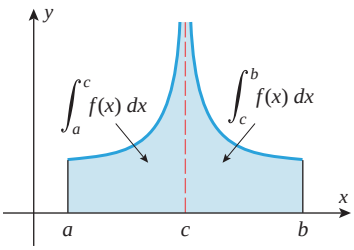
$$\int_a^b f(x)\,dx = \lim_{k \to a^+} \int_k^b f(x)\,dx \tag{5}$$

The integral is said to ***converge*** if the indicated limit exists and ***diverge*** if it does not.

If $f$ is continuous on the interval $[a, b]$, except for an infinite discontinuity at a point $c$ in $(a, b)$, then the ***improper integral of f over the interval [a, b]*** is defined as

$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx \tag{6}$$

where the two integrals on the right side are themselves improper. The improper integral on the left side is said to ***converge*** if *both* terms on the right side converge and ***diverge*** if *either* term on the right side diverges (Figure 7.8.9).



▲ **Figure 7.8.9**

**▶ Example 6** Evaluate

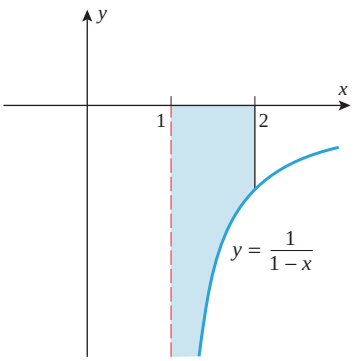
$$\text{(a)} \int_1^2 \frac{dx}{1-x} \qquad \text{(b)} \int_1^4 \frac{dx}{(x-2)^{2/3}}$$

***Solution (a).*** The integral is improper because the integrand approaches $-\infty$ as $x$ approaches the lower limit 1 from the right (Figure 7.8.10). From Definition 7.8.5 we obtain

$$\int_1^2 \frac{dx}{1-x} = \lim_{k \to 1^+} \int_k^2 \frac{dx}{1-x} = \lim_{k \to 1^+} \Big[-\ln|1-x|\Big]_k^2$$

$$= \lim_{k \to 1^+} \big[-\ln|-1| + \ln|1-k|\big] = \lim_{k \to 1^+} \ln|1-k| = -\infty$$

so the integral diverges.



▲ **Figure 7.8.10**

***Solution (b).*** The integral is improper because the integrand approaches $+\infty$ at $x = 2$, which is inside the interval of integration. From Definition 7.8.5 we obtain

$$\int_1^4 \frac{dx}{(x-2)^{2/3}} = \int_1^2 \frac{dx}{(x-2)^{2/3}} + \int_2^4 \frac{dx}{(x-2)^{2/3}} \tag{7}$$

and we must investigate the convergence of both improper integrals on the right. Since

$$\int_1^2 \frac{dx}{(x-2)^{2/3}} = \lim_{k \to 2^-} \int_1^k \frac{dx}{(x-2)^{2/3}} = \lim_{k \to 2^-} \Big[3(k-2)^{1/3} - 3(1-2)^{1/3}\Big] = 3$$

$$\int_2^4 \frac{dx}{(x-2)^{2/3}} = \lim_{k \to 2^+} \int_k^4 \frac{dx}{(x-2)^{2/3}} = \lim_{k \to 2^+} \Big[3(4-2)^{1/3} - 3(k-2)^{1/3}\Big] = 3\sqrt[3]{2}$$

we have from (7) that

$$\int_1^4 \frac{dx}{(x-2)^{2/3}} = 3 + 3\sqrt[3]{2} \quad \blacktriangleleft$$

**WARNING** It is sometimes tempting to apply the Fundamental Theorem of Calculus directly to an improper integral without taking the appropriate limits. To illustrate what can go wrong with this procedure, suppose we fail to recognize that the integral

$$\int_0^2 \frac{dx}{(x-1)^2} \tag{8}$$

is improper and mistakenly evaluate this integral as

$$-\frac{1}{x-1}\Big]_0^2 = -1-(1) = -2$$

This result is clearly incorrect because the integrand is never negative and hence the integral cannot be negative! To evaluate (8) correctly we should first write

$$\int_0^2 \frac{dx}{(x-1)^2} = \int_0^1 \frac{dx}{(x-1)^2} + \int_1^2 \frac{dx}{(x-1)^2}$$

and then treat each term as an improper integral. For the first term,

$$\int_0^1 \frac{dx}{(x-1)^2} = \lim_{k\to 1^-}\int_0^k \frac{dx}{(x-1)^2} = \lim_{k\to 1^-}\left[-\frac{1}{k-1}-1\right] = +\infty$$

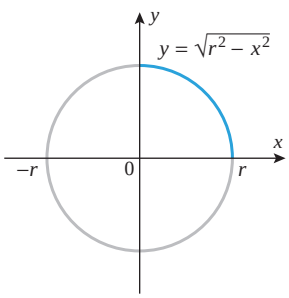
so (8) diverges.

## ARC LENGTH AND SURFACE AREA USING IMPROPER INTEGRALS

In Definitions 6.4.2 and 6.5.2 for arc length and surface area we required the function $f$ to be smooth (continuous first derivative) to ensure the integrability in the resulting formula. However, smoothness is overly restrictive since some of the most basic formulas in geometry involve functions that are not smooth but lead to convergent improper integrals. Accordingly, let us agree to extend the definitions of arc length and surface area to allow functions that are not smooth, but for which the resulting integral in the formula converges.

**▶ Example 7** Derive the formula for the circumference of a circle of radius $r$.

***Solution.*** For convenience, let us assume that the circle is centered at the origin, in which case its equation is $x^2+y^2=r^2$. We will find the arc length of the portion of the circle that lies in the first quadrant and then multiply by 4 to obtain the total circumference (Figure 7.8.11).



▲ Figure 7.8.11

Since the equation of the upper semicircle is $y=\sqrt{r^2-x^2}$, it follows from Formula (4) of Section 6.4 that the circumference $C$ is

$$C = 4\int_0^r \sqrt{1+(dy/dx)^2}\,dx = 4\int_0^r \sqrt{1+\left(-\frac{x}{\sqrt{r^2-x^2}}\right)^2}\,dx$$
$$= 4r\int_0^r \frac{dx}{\sqrt{r^2-x^2}}$$

This integral is improper because of the infinite discontinuity at $x=r$, and hence we evaluate it by writing

$$C = 4r\lim_{k\to r^-}\int_0^k \frac{dx}{\sqrt{r^2-x^2}}$$
$$= 4r\lim_{k\to r^-}\left[\sin^{-1}\left(\frac{x}{r}\right)\right]_0^k$$

Formula (77) in the Endpaper Integral Table

$$= 4r\lim_{k\to r^-}\left[\sin^{-1}\left(\frac{k}{r}\right)-\sin^{-1}0\right]$$
$$= 4r[\sin^{-1}1-\sin^{-1}0] = 4r\left(\frac{\pi}{2}-0\right) = 2\pi r \quad \blacktriangleleft$$

## ✔ QUICK CHECK EXERCISES 7.8 (See page 557 for answers.)

**1.** In each part, determine whether the integral is improper, and if so, explain why. Do not evaluate the integrals.

(a) $\displaystyle\int_{\pi/4}^{3\pi/4} \cot x\,dx$ (b) $\displaystyle\int_{\pi/4}^{\pi} \cot x\,dx$

(c) $\displaystyle\int_{0}^{+\infty} \frac{1}{x^2+1}\,dx$ (d) $\displaystyle\int_{1}^{+\infty} \frac{1}{x^2-1}\,dx$

**2.** Express each improper integral in Quick Check Exercise 1 in terms of one or more appropriate limits. Do not evaluate the limits.

**3.** The improper integral

$$\int_{1}^{+\infty} x^{-p}\,dx$$

converges to _____ provided _____.

**4.** Evaluate the integrals that converge.

(a) $\displaystyle\int_{0}^{+\infty} e^{-x}\,dx$ (b) $\displaystyle\int_{0}^{+\infty} e^{x}\,dx$

(c) $\displaystyle\int_{0}^{1} \frac{1}{x^3}\,dx$ (d) $\displaystyle\int_{0}^{1} \frac{1}{\sqrt[3]{x^2}}\,dx$

## EXERCISE SET 7.8 Graphing Utility C CAS

**1.** In each part, determine whether the integral is improper, and if so, explain why.

(a) $\displaystyle\int_{1}^{5} \frac{dx}{x-3}$ (b) $\displaystyle\int_{1}^{5} \frac{dx}{x+3}$ (c) $\displaystyle\int_{0}^{1} \ln x\,dx$

(d) $\displaystyle\int_{1}^{+\infty} e^{-x}\,dx$ (e) $\displaystyle\int_{-\infty}^{+\infty} \frac{dx}{\sqrt[3]{x-1}}$ (f) $\displaystyle\int_{0}^{\pi/4} \tan x\,dx$

**2.** In each part, determine all values of $p$ for which the integral is improper.

(a) $\displaystyle\int_{0}^{1} \frac{dx}{x^p}$ (b) $\displaystyle\int_{1}^{2} \frac{dx}{x-p}$ (c) $\displaystyle\int_{0}^{1} e^{-px}\,dx$

**3–32** Evaluate the integrals that converge.

**3.** $\displaystyle\int_{0}^{+\infty} e^{-2x}\,dx$

**4.** $\displaystyle\int_{-1}^{+\infty} \frac{x}{1+x^2}\,dx$

**5.** $\displaystyle\int_{3}^{+\infty} \frac{2}{x^2-1}\,dx$

**6.** $\displaystyle\int_{0}^{+\infty} xe^{-x^2}\,dx$

**7.** $\displaystyle\int_{e}^{+\infty} \frac{1}{x\ln^3 x}\,dx$

**8.** $\displaystyle\int_{2}^{+\infty} \frac{1}{x\sqrt{\ln x}}\,dx$

**9.** $\displaystyle\int_{-\infty}^{0} \frac{dx}{(2x-1)^3}$

**10.** $\displaystyle\int_{-\infty}^{3} \frac{dx}{x^2+9}$

**11.** $\displaystyle\int_{-\infty}^{0} e^{3x}\,dx$

**12.** $\displaystyle\int_{-\infty}^{0} \frac{e^x\,dx}{3-2e^x}$

**13.** $\displaystyle\int_{-\infty}^{+\infty} x\,dx$

**14.** $\displaystyle\int_{-\infty}^{+\infty} \frac{x}{\sqrt{x^2+2}}\,dx$

**15.** $\displaystyle\int_{-\infty}^{+\infty} \frac{x}{(x^2+3)^2}\,dx$

**16.** $\displaystyle\int_{-\infty}^{+\infty} \frac{e^{-t}}{1+e^{-2t}}\,dt$

**17.** $\displaystyle\int_{0}^{4} \frac{dx}{(x-4)^2}$

**18.** $\displaystyle\int_{0}^{8} \frac{dx}{\sqrt[3]{x}}$

**19.** $\displaystyle\int_{0}^{\pi/2} \tan x\,dx$

**20.** $\displaystyle\int_{0}^{4} \frac{dx}{\sqrt{4-x}}$

**21.** $\displaystyle\int_{0}^{1} \frac{dx}{\sqrt{1-x^2}}$

**22.** $\displaystyle\int_{-3}^{1} \frac{x\,dx}{\sqrt{9-x^2}}$

**23.** $\displaystyle\int_{\pi/3}^{\pi/2} \frac{\sin x}{\sqrt{1-2\cos x}}\,dx$

**24.** $\displaystyle\int_{0}^{\pi/4} \frac{\sec^2 x}{1-\tan x}\,dx$

**25.** $\displaystyle\int_{0}^{3} \frac{dx}{x-2}$

**26.** $\displaystyle\int_{-2}^{2} \frac{dx}{x^2}$

**27.** $\displaystyle\int_{-1}^{8} x^{-1/3}\,dx$

**28.** $\displaystyle\int_{0}^{1} \frac{dx}{(x-1)^{2/3}}$

**29.** $\displaystyle\int_{0}^{+\infty} \frac{1}{x^2}\,dx$

**30.** $\displaystyle\int_{1}^{+\infty} \frac{dx}{x\sqrt{x^2-1}}$

**31.** $\displaystyle\int_{0}^{1} \frac{dx}{\sqrt{x}(x+1)}$

**32.** $\displaystyle\int_{0}^{+\infty} \frac{dx}{\sqrt{x}(x+1)}$

**33–36 True–False** Determine whether the statement is true or false. Explain your answer.

**33.** $\displaystyle\int_{1}^{+\infty} x^{-4/3}\,dx$ converges to 3.

**34.** If $f$ is continuous on $[a, +\infty)$ and $\lim_{x\to+\infty} f(x) = 1$, then $\int_{a}^{+\infty} f(x)\,dx$ converges.

**35.** $\displaystyle\int_{1}^{2} \frac{1}{x(x-3)}\,dx$ is an improper integral.

**36.** $\displaystyle\int_{-1}^{1} \frac{1}{x^3}\,dx = 0$

**37–40** Make the $u$-substitution and evaluate the resulting definite integral.

**37.** $\displaystyle\int_{0}^{+\infty} \frac{e^{-\sqrt{x}}}{\sqrt{x}}\,dx;\ u = \sqrt{x}$ [*Note:* $u \to +\infty$ as $x \to +\infty$.]

**38.** $\displaystyle\int_{12}^{+\infty} \frac{dx}{\sqrt{x}(x+4)};\ u = \sqrt{x}$ [*Note:* $u \to +\infty$ as $x \to +\infty$.]

**39.** $\displaystyle\int_{0}^{+\infty} \frac{e^{-x}}{\sqrt{1-e^{-x}}}\,dx;\ u = 1 - e^{-x}$ [*Note:* $u \to 1$ as $x \to +\infty$.]

**40.** $\displaystyle\int_0^{+\infty} \frac{e^{-x}}{\sqrt{1-e^{-2x}}}\,dx;\ u = e^{-x}$

C **41–42** Express the improper integral as a limit, and then evaluate that limit with a CAS. Confirm the answer by evaluating the integral directly with the CAS. ■

**41.** $\displaystyle\int_0^{+\infty} e^{-x}\cos x\,dx$ **42.** $\displaystyle\int_0^{+\infty} xe^{-3x}\,dx$

C **43.** In each part, try to evaluate the integral exactly with a CAS. If your result is not a simple numerical answer, then use the CAS to find a numerical approximation of the integral.

(a) $\displaystyle\int_{-\infty}^{+\infty} \frac{1}{x^8+x+1}\,dx$ (b) $\displaystyle\int_0^{+\infty} \frac{1}{\sqrt{1+x^3}}\,dx$

(c) $\displaystyle\int_1^{+\infty} \frac{\ln x}{e^x}\,dx$ (d) $\displaystyle\int_1^{+\infty} \frac{\sin x}{x^2}\,dx$

C **44.** In each part, confirm the result with a CAS.

(a) $\displaystyle\int_0^{+\infty} \frac{\sin x}{\sqrt{x}}\,dx = \sqrt{\frac{\pi}{2}}$ (b) $\displaystyle\int_{-\infty}^{+\infty} e^{-x^2}\,dx = \sqrt{\pi}$

(c) $\displaystyle\int_0^1 \frac{\ln x}{1+x}\,dx = -\frac{\pi^2}{12}$

**45.** Find the length of the curve $y = (4 - x^{2/3})^{3/2}$ over the interval $[0, 8]$.

**46.** Find the length of the curve $y = \sqrt{4-x^2}$ over the interval $[0, 2]$.

**47–48** Use L'Hôpital's rule to help evaluate the improper integral. ■

**47.** $\displaystyle\int_0^1 \ln x\,dx$ **48.** $\displaystyle\int_1^{+\infty} \frac{\ln x}{x^2}\,dx$

**49.** Find the area of the region between the $x$-axis and the curve $y = e^{-3x}$ for $x \geq 0$.

**50.** Find the area of the region between the $x$-axis and the curve $y = 8/(x^2-4)$ for $x \geq 4$.

**51.** Suppose that the region between the $x$-axis and the curve $y = e^{-x}$ for $x \geq 0$ is revolved about the $x$-axis.

(a) Find the volume of the solid that is generated.

(b) Find the surface area of the solid.

**FOCUS ON CONCEPTS**

**52.** Suppose that $f$ and $g$ are continuous functions and that

$$0 \leq f(x) \leq g(x)$$

if $x \geq a$. Give a reasonable informal argument using areas to explain why the following results are true.

(a) If $\int_a^{+\infty} f(x)\,dx$ diverges, then $\int_a^{+\infty} g(x)\,dx$ diverges.

(b) If $\int_a^{+\infty} g(x)\,dx$ converges, then $\int_a^{+\infty} f(x)\,dx$ converges and $\int_a^{+\infty} f(x)\,dx \leq \int_a^{+\infty} g(x)\,dx$.

[*Note:* The results in this exercise are sometimes called ***comparison tests*** for improper integrals.]

**53–56** Use the results in Exercise 52. ■

**53.** (a) Confirm graphically and algebraically that

$$e^{-x^2} \leq e^{-x} \quad (x \geq 1)$$

(b) Evaluate the integral

$$\int_1^{+\infty} e^{-x}\,dx$$

(c) What does the result obtained in part (b) tell you about the integral

$$\int_1^{+\infty} e^{-x^2}\,dx?$$

**54.** (a) Confirm graphically and algebraically that

$$\frac{1}{2x+1} \leq \frac{e^x}{2x+1} \quad (x \geq 0)$$

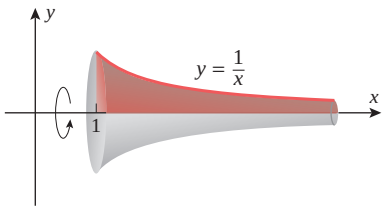
(b) Evaluate the integral

$$\int_0^{+\infty} \frac{dx}{2x+1}$$

(c) What does the result obtained in part (b) tell you about the integral

$$\int_0^{+\infty} \frac{e^x}{2x+1}\,dx?$$

**55.** Let $R$ be the region to the right of $x = 1$ that is bounded by the $x$-axis and the curve $y = 1/x$. When this region is revolved about the $x$-axis it generates a solid whose surface is known as ***Gabriel's Horn*** (for reasons that should be clear from the accompanying figure). Show that the solid has a finite volume but its surface has an infinite area. [*Note:* It has been suggested that if one could saturate the interior of the solid with paint and allow it to seep through to the surface, then one could paint an infinite surface with a finite amount of paint! What do you think?]



◀ **Figure Ex-55**

**56.** In each part, use Exercise 52 to determine whether the integral converges or diverges. If it converges, then use part (b) of that exercise to find an upper bound on the value of the integral.

(a) $\displaystyle\int_2^{+\infty} \frac{\sqrt{x^3+1}}{x}\,dx$ (b) $\displaystyle\int_2^{+\infty} \frac{x}{x^5+1}\,dx$

(c) $\displaystyle\int_0^{+\infty} \frac{xe^x}{2x+1}\,dx$

**FOCUS ON CONCEPTS**

**57.** Sketch the region whose area is

$$\int_0^{+\infty} \frac{dx}{1+x^2}$$

and use your sketch to show that

$$\int_0^{+\infty} \frac{dx}{1+x^2} = \int_0^1 \sqrt{\frac{1-y}{y}}\, dy$$

**58.** (a) Give a reasonable informal argument, based on areas, that explains why the integrals

$$\int_0^{+\infty} \sin x\, dx \quad \text{and} \quad \int_0^{+\infty} \cos x\, dx$$

diverge.

(b) Show that $\displaystyle\int_0^{+\infty} \frac{\cos\sqrt{x}}{\sqrt{x}}\, dx$ diverges.

**59.** In electromagnetic theory, the magnetic potential at a point on the axis of a circular coil is given by

$$u = \frac{2\pi NIr}{k} \int_a^{+\infty} \frac{dx}{(r^2+x^2)^{3/2}}$$

where $N$, $I$, $r$, $k$, and $a$ are constants. Find $u$.

C **60.** The *average speed*, $\bar{v}$, of the molecules of an ideal gas is given by

$$\bar{v} = \frac{4}{\sqrt{\pi}} \left(\frac{M}{2RT}\right)^{3/2} \int_0^{+\infty} v^3 e^{-Mv^2/(2RT)}\, dv$$

and the *root-mean-square speed*, $v_{\text{rms}}$, by

$$v_{\text{rms}}^2 = \frac{4}{\sqrt{\pi}} \left(\frac{M}{2RT}\right)^{3/2} \int_0^{+\infty} v^4 e^{-Mv^2/(2RT)}\, dv$$

where $v$ is the molecular speed, $T$ is the gas temperature, $M$ is the molecular weight of the gas, and $R$ is the gas constant.

(a) Use a CAS to show that

$$\int_0^{+\infty} x^3 e^{-a^2x^2}\, dx = \frac{1}{2a^4}, \quad a > 0$$

and use this result to show that $\bar{v} = \sqrt{8RT/(\pi M)}$.

(b) Use a CAS to show that

$$\int_0^{+\infty} x^4 e^{-a^2x^2}\, dx = \frac{3\sqrt{\pi}}{8a^5}, \quad a > 0$$

and use this result to show that $v_{\text{rms}} = \sqrt{3RT/M}$.

**61–62** Medication can be administered to a patient using a variety of methods. For a given method, let $c(t)$ denote the concentration of medication in the patient's bloodstream (measured in mg/L) $t$ hours after the dose is given. The area under the curve $c = c(t)$ over the time interval $[0, +\infty)$ indicates the "availability" of the medication for the patient's body. Determine which method provides the greater availability. ■

**61.** Method 1: $c_1(t) = 5(e^{-0.2t} - e^{-t})$;
Method 2: $c_2(t) = 4(e^{-0.2t} - e^{-3t})$

**62.** Method 1: $c_1(t) = 6(e^{-0.4t} - e^{-1.3t})$;
Method 2: $c_2(t) = 5(e^{-0.4t} - e^{-3t})$

**63.** In Exercise 25 of Section 6.6, we determined the work required to lift a 6000 lb satellite to an orbital position that is 1000 mi above the Earth's surface. The ideas discussed in that exercise will be needed here.

(a) Find a definite integral that represents the work required to lift a 6000 lb satellite to a position $b$ miles above the Earth's surface.

(b) Find a definite integral that represents the work required to lift a 6000 lb satellite an "infinite distance" above the Earth's surface. Evaluate the integral. [*Note:* The result obtained here is sometimes called the work required to "escape" the Earth's gravity.]

**64–65** A ***transform*** is a formula that converts or "transforms" one function into another. Transforms are used in applications to convert a difficult problem into an easier problem whose solution can then be used to solve the original difficult problem. The ***Laplace transform*** of a function $f(t)$, which plays an important role in the study of differential equations, is denoted by $\mathcal{L}\{f(t)\}$ and is defined by

$$\mathcal{L}\{f(t)\} = \int_0^{+\infty} e^{-st} f(t)\, dt$$

In this formula $s$ is treated as a constant in the integration process; thus, the Laplace transform has the effect of transforming $f(t)$ into a function of $s$. Use this formula in these exercises. ■

**64.** Show that

(a) $\mathcal{L}\{1\} = \dfrac{1}{s}, \ s > 0$ (b) $\mathcal{L}\{e^{2t}\} = \dfrac{1}{s-2}, \ s > 2$

(c) $\mathcal{L}\{\sin t\} = \dfrac{1}{s^2+1}, \ s > 0$

(d) $\mathcal{L}\{\cos t\} = \dfrac{s}{s^2+1}, \ s > 0.$

**65.** In each part, find the Laplace transform.

(a) $f(t) = t, \ s > 0$ (b) $f(t) = t^2, \ s > 0$

(c) $f(t) = \begin{cases} 0, & t < 3 \\ 1, & t \geq 3 \end{cases}, \quad s > 0$

C **66.** Later in the text, we will show that

$$\int_0^{+\infty} e^{-x^2}\, dx = \tfrac{1}{2}\sqrt{\pi}$$

Confirm that this is reasonable by using a CAS or a calculator with a numerical integration capability.

**67.** Use the result in Exercise 66 to show that

(a) $\displaystyle\int_{-\infty}^{+\infty} e^{-ax^2}\, dx = \sqrt{\frac{\pi}{a}}, \ a > 0$

(b) $\displaystyle\frac{1}{\sqrt{2\pi}\sigma} \int_{-\infty}^{+\infty} e^{-x^2/2\sigma^2}\, dx = 1, \ \sigma > 0.$

**68–69** A convergent improper integral over an infinite interval can be approximated by first replacing the infinite limit(s) of integration by finite limit(s), then using a numerical integration technique, such as Simpson's rule, to approximate the integral with finite limit(s). This technique is illustrated in these exercises. ■

**68.** Suppose that the integral in Exercise 66 is approximated by first writing it as

$$\int_0^{+\infty} e^{-x^2}\,dx = \int_0^K e^{-x^2}\,dx + \int_K^{+\infty} e^{-x^2}\,dx$$

then dropping the second term, and then applying Simpson's rule to the integral

$$\int_0^K e^{-x^2}\,dx$$

The resulting approximation has two sources of error: the error from Simpson's rule and the error

$$E = \int_K^{+\infty} e^{-x^2}\,dx$$

that results from discarding the second term. We call $E$ the ***truncation error***.

(a) Approximate the integral in Exercise 66 by applying Simpson's rule with $n = 10$ subdivisions to the integral

$$\int_0^3 e^{-x^2}\,dx$$

Round your answer to four decimal places and compare it to $\frac{1}{2}\sqrt{\pi}$ rounded to four decimal places.

(b) Use the result that you obtained in Exercise 52 and the fact that $e^{-x^2} \le \frac{1}{3}xe^{-x^2}$ for $x \ge 3$ to show that the truncation error for the approximation in part (a) satisfies $0 < E < 2.1 \times 10^{-5}$.

**69.** (a) It can be shown that

$$\int_0^{+\infty} \frac{1}{x^6+1}\,dx = \frac{\pi}{3}$$

Approximate this integral by applying Simpson's rule with $n = 20$ subdivisions to the integral

$$\int_0^4 \frac{1}{x^6+1}\,dx$$

Round your answer to three decimal places and compare it to $\pi/3$ rounded to three decimal places.

(b) Use the result that you obtained in Exercise 52 and the fact that $1/(x^6+1) < 1/x^6$ for $x \ge 4$ to show that the truncation error for the approximation in part (a) satisfies $0 < E < 2 \times 10^{-4}$.

**70.** For what values of $p$ does $\displaystyle\int_0^{+\infty} e^{px}\,dx$ converge?

**71.** Show that $\displaystyle\int_0^1 dx/x^p$ converges if $p < 1$ and diverges if $p \ge 1$.

C **72.** It is sometimes possible to convert an improper integral into a "proper" integral having the same value by making an appropriate substitution. Evaluate the following integral by making the indicated substitution, and investigate what happens if you evaluate the integral directly using a CAS.

$$\int_0^1 \sqrt{\frac{1+x}{1-x}}\,dx;\ u = \sqrt{1-x}$$

**73–74** Transform the given improper integral into a proper integral by making the stated $u$-substitution; then approximate the proper integral by Simpson's rule with $n = 10$ subdivisions. Round your answer to three decimal places. ■

**73.** $\displaystyle\int_0^1 \frac{\cos x}{\sqrt{x}}\,dx;\ u = \sqrt{x}$

**74.** $\displaystyle\int_0^1 \frac{\sin x}{\sqrt{1-x}}\,dx;\ u = \sqrt{1-x}$

**75. Writing** What is "improper" about an integral over an infinite interval? Explain why Definition 5.5.1 for $\int_a^b f(x)\,dx$ fails for $\int_a^{+\infty} f(x)\,dx$. Discuss a strategy for assigning a value to $\int_a^{+\infty} f(x)\,dx$.

**76. Writing** What is "improper" about a definite integral over an interval on which the integrand has an infinite discontinuity? Explain why Definition 5.5.1 for $\int_a^b f(x)\,dx$ fails if the graph of $f$ has a vertical asymptote at $x = a$. Discuss a strategy for assigning a value to $\int_a^b f(x)\,dx$ in this circumstance.

## ✔ QUICK CHECK ANSWERS 7.8

**1.** (a) proper (b) improper, since $\cot x$ has an infinite discontinuity at $x = \pi$ (c) improper, since there is an infinite interval of integration (d) improper, since there is an infinite interval of integration and the integrand has an infinite discontinuity at $x = 1$

**2.** (b) $\displaystyle\lim_{b\to\pi^-}\int_{\pi/4}^b \cot x\,dx$ (c) $\displaystyle\lim_{b\to+\infty}\int_0^b \frac{1}{x^2+1}\,dx$ (d) $\displaystyle\lim_{a\to1^+}\int_a^2 \frac{1}{x^2-1}\,dx + \lim_{b\to+\infty}\int_2^b \frac{1}{x^2-1}\,dx$ **3.** $\dfrac{1}{p-1};\ p > 1$

**4.** (a) 1 (b) diverges (c) diverges (d) 3

## CHAPTER 7 REVIEW EXERCISES

**1–6** Evaluate the given integral with the aid of an appropriate $u$-substitution. ■

**1.** $\displaystyle\int \sqrt{4+9x}\,dx$

**2.** $\displaystyle\int \frac{1}{\sec \pi x}\,dx$

**3.** $\displaystyle\int \sqrt{\cos x}\sin x\,dx$

**4.** $\displaystyle\int \frac{dx}{x\ln x}$

**5.** $\displaystyle\int x\tan^2(x^2)\sec^2(x^2)\,dx$

**6.** $\displaystyle\int_0^9 \frac{\sqrt{x}}{x+9}\,dx$

**7.** (a) Evaluate the integral

$$\int \frac{1}{\sqrt{2x-x^2}}\,dx$$

three ways: using the substitution $u = \sqrt{x}$, using the substitution $u = \sqrt{2-x}$, and completing the square.

(b) Show that the answers in part (a) are equivalent.

**8.** Evaluate the integral $\displaystyle\int_0^1 \frac{x^3}{\sqrt{x^2+1}}\,dx$
(a) using integration by parts
(b) using the substitution $u = \sqrt{x^2+1}$.

**9–12** Use integration by parts to evaluate the integral. ■

**9.** $\displaystyle\int xe^{-x}\,dx$ **10.** $\displaystyle\int x\sin 2x\,dx$

**11.** $\displaystyle\int \ln(2x+3)\,dx$ **12.** $\displaystyle\int_0^{1/2} \tan^{-1}(2x)\,dx$

**13.** Evaluate $\int 8x^4\cos 2x\,dx$ using tabular integration by parts.

**14.** A particle moving along the $x$-axis has velocity function $v(t) = t^2e^{-t}$. How far does the particle travel from time $t = 0$ to $t = 5$?

**15–20** Evaluate the integral. ■

**15.** $\displaystyle\int \sin^2 5\theta\,d\theta$ **16.** $\displaystyle\int \sin^3 2x\cos^2 2x\,dx$

**17.** $\displaystyle\int \sin x\cos 2x\,dx$ **18.** $\displaystyle\int_0^{\pi/6} \sin 2x\cos 4x\,dx$

**19.** $\displaystyle\int \sin^4 2x\,dx$ **20.** $\displaystyle\int x\cos^5(x^2)\,dx$

**21–26** Evaluate the integral by making an appropriate trigonometric substitution. ■

**21.** $\displaystyle\int \frac{x^2}{\sqrt{9-x^2}}\,dx$ **22.** $\displaystyle\int \frac{dx}{x^2\sqrt{16-x^2}}$

**23.** $\displaystyle\int \frac{dx}{\sqrt{x^2-1}}$ **24.** $\displaystyle\int \frac{x^2}{\sqrt{x^2-25}}\,dx$

**25.** $\displaystyle\int \frac{x^2}{\sqrt{9+x^2}}\,dx$ **26.** $\displaystyle\int \frac{\sqrt{1+4x^2}}{x}\,dx$

**27–32** Evaluate the integral using the method of partial fractions. ■

**27.** $\displaystyle\int \frac{dx}{x^2+3x-4}$ **28.** $\displaystyle\int \frac{dx}{x^2+8x+7}$

**29.** $\displaystyle\int \frac{x^2+2}{x+2}\,dx$ **30.** $\displaystyle\int \frac{x^2+x-16}{(x-1)(x-3)^2}\,dx$

**31.** $\displaystyle\int \frac{x^2}{(x+2)^3}\,dx$ **32.** $\displaystyle\int \frac{dx}{x^3+x}$

**33.** Consider the integral $\displaystyle\int \frac{1}{x^3-x}\,dx$.
(a) Evaluate the integral using the substitution $x = \sec\theta$. For what values of $x$ is your result valid?
(b) Evaluate the integral using the substitution $x = \sin\theta$. For what values of $x$ is your result valid?
(c) Evaluate the integral using the method of partial fractions. For what values of $x$ is your result valid?

**34.** Find the area of the region that is enclosed by the curves $y = (x-3)/(x^3+x^2)$, $y = 0$, $x = 1$, and $x = 2$.

**35–40** Use the Endpaper Integral Table to evaluate the integral. ■

**35.** $\displaystyle\int \sin 7x\cos 9x\,dx$ **36.** $\displaystyle\int (x^3-x^2)e^{-x}\,dx$

**37.** $\displaystyle\int x\sqrt{x-x^2}\,dx$ **38.** $\displaystyle\int \frac{dx}{x\sqrt{4x+3}}$

**39.** $\displaystyle\int \tan^2 2x\,dx$ **40.** $\displaystyle\int \frac{3x-1}{2+x^2}\,dx$

**41–42** Approximate the integral using (a) the midpoint approximation $M_{10}$, (b) the trapezoidal approximation $T_{10}$, and (c) Simpson's rule approximation $S_{20}$. In each case, find the exact value of the integral and approximate the absolute error. Express your answers to at least four decimal places. ■

**41.** $\displaystyle\int_1^3 \frac{1}{\sqrt{x+1}}\,dx$ **42.** $\displaystyle\int_{-1}^1 \frac{1}{1+x^2}\,dx$

**43–44** Use inequalities (12), (13), and (14) of Section 7.7 to find upper bounds on the errors in parts (a), (b), or (c) of the indicated exercise. ■

**43.** Exercise 41 **44.** Exercise 42

**45–46** Use inequalities (12), (13), and (14) of Section 7.7 to find a number $n$ of subintervals for (a) the midpoint approximation $M_n$, (b) the trapezoidal approximation $T_n$, and (c) Simpson's rule approximation $S_n$ to ensure the absolute error will be less than $10^{-4}$. ■

**45.** Exercise 41 **46.** Exercise 42

**47–50** Evaluate the integral if it converges. ■

**47.** $\displaystyle\int_0^{+\infty} e^{-x}\,dx$ **48.** $\displaystyle\int_{-\infty}^2 \frac{dx}{x^2+4}$

**49.** $\displaystyle\int_0^9 \frac{dx}{\sqrt{9-x}}$ **50.** $\displaystyle\int_0^1 \frac{1}{2x-1}\,dx$

**51.** Find the area that is enclosed between the $x$-axis and the curve $y = (\ln x - 1)/x^2$ for $x \geq e$.

**52.** Find the volume of the solid that is generated when the region between the $x$-axis and the curve $y = e^{-x}$ for $x \geq 0$ is revolved about the $y$-axis.

**53.** Find a positive value of $a$ that satisfies the equation

$$\int_0^{+\infty} \frac{1}{x^2+a^2}\,dx = 1$$

**54.** Consider the following methods for evaluating integrals: $u$-substitution, integration by parts, partial fractions, reduction formulas, and trigonometric substitutions. In each part, state the approach that you would try first to evaluate the integral. If none of them seems appropriate, then say so. You need not evaluate the integral.
(a) $\displaystyle\int x\sin x\,dx$ (b) $\displaystyle\int \cos x\sin x\,dx$

(cont.)

(c) $\int \tan^7 x\,dx$ (d) $\int \tan^7 x \sec^2 x\,dx$

(e) $\int \dfrac{3x^2}{x^3+1}\,dx$ (f) $\int \dfrac{3x^2}{(x+1)^3}\,dx$

(g) $\int \tan^{-1} x\,dx$ (h) $\int \sqrt{4-x^2}\,dx$

(i) $\int x\sqrt{4-x^2}\,dx$

**55–74** Evaluate the integral. ■

**55.** $\int \dfrac{dx}{(3+x^2)^{3/2}}$ **56.** $\int x\cos 3x\,dx$

**57.** $\int_0^{\pi/4} \tan^7\theta\,d\theta$ **58.** $\int \dfrac{\cos\theta}{\sin^2\theta - 6\sin\theta + 12}\,d\theta$

**59.** $\int \sin^2 2x\cos^3 2x\,dx$ **60.** $\int_0^4 \dfrac{1}{(x-3)^2}\,dx$

**61.** $\int e^{2x}\cos 3x\,dx$ **62.** $\int_{-1/\sqrt{2}}^{1/\sqrt{2}} (1-2x^2)^{3/2}\,dx$

**63.** $\int \dfrac{dx}{(x-1)(x+2)(x-3)}$ **64.** $\int_0^{1/3} \dfrac{dx}{(4-9x^2)^2}$

**65.** $\int_4^8 \dfrac{\sqrt{x-4}}{x}\,dx$ **66.** $\int_0^{\ln 2} \sqrt{e^x-1}\,dx$

**67.** $\int \dfrac{1}{\sqrt{e^x+1}}\,dx$ **68.** $\int \dfrac{dx}{x(x^2+x+1)}$

**69.** $\int_0^{1/2} \sin^{-1} x\,dx$ **70.** $\int \tan^5 4x\sec^4 4x\,dx$

**71.** $\int \dfrac{x+3}{\sqrt{x^2+2x+2}}\,dx$ **72.** $\int \dfrac{\sec^2\theta}{\tan^3\theta - \tan^2\theta}\,d\theta$

**73.** $\int_a^{+\infty} \dfrac{x}{(x^2+1)^2}\,dx$

**74.** $\int_0^{+\infty} \dfrac{dx}{a^2+b^2x^2}, \quad a, b > 0$

## CHAPTER 7 MAKING CONNECTIONS C CAS

**1.** Recall from Theorem 3.3.1 and the discussion preceding it that if $f'(x) > 0$, then the function $f$ is increasing and has an inverse function. Parts (a), (b), and (c) of this problem show that if this condition is satisfied and if $f'$ is continuous, then a definite integral of $f^{-1}$ can be expressed in terms of a definite integral of $f$.

(a) Use integration by parts to show that

$$\int_a^b f(x)\,dx = bf(b) - af(a) - \int_a^b xf'(x)\,dx$$

(b) Use the result in part (a) to show that if $y = f(x)$, then

$$\int_a^b f(x)\,dx = bf(b) - af(a) - \int_{f(a)}^{f(b)} f^{-1}(y)\,dy$$

(c) Show that if we let $\alpha = f(a)$ and $\beta = f(b)$, then the result in part (b) can be written as

$$\int_\alpha^\beta f^{-1}(x)\,dx = \beta f^{-1}(\beta) - \alpha f^{-1}(\alpha) - \int_{f^{-1}(\alpha)}^{f^{-1}(\beta)} f(x)\,dx$$

**2.** In each part, use the result in Exercise 1 to obtain the equation, and then confirm that the equation is correct by performing the integrations.

(a) $\displaystyle\int_0^{1/2} \sin^{-1} x\,dx = \tfrac{1}{2}\sin^{-1}\left(\tfrac{1}{2}\right) - \int_0^{\pi/6} \sin x\,dx$

(b) $\displaystyle\int_e^{e^2} \ln x\,dx = (2e^2 - e) - \int_1^2 e^x\,dx$

**3.** The ***Gamma function***, $\Gamma(x)$, is defined as

$$\Gamma(x) = \int_0^{+\infty} t^{x-1}e^{-t}\,dt$$

It can be shown that this improper integral converges if and only if $x > 0$.

(a) Find $\Gamma(1)$.

(b) Prove: $\Gamma(x+1) = x\Gamma(x)$ for all $x > 0$. [*Hint:* Use integration by parts.]

(c) Use the results in parts (a) and (b) to find $\Gamma(2)$, $\Gamma(3)$, and $\Gamma(4)$; and then make a conjecture about $\Gamma(n)$ for positive integer values of $n$.

(d) Show that $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$. [*Hint:* See Exercise 66 of Section 7.8.]

(e) Use the results obtained in parts (b) and (d) to show that $\Gamma\left(\frac{3}{2}\right) = \frac{1}{2}\sqrt{\pi}$ and $\Gamma\left(\frac{5}{2}\right) = \frac{3}{4}\sqrt{\pi}$.

**4.** Refer to the Gamma function defined in Exercise 3 to show that

(a) $\displaystyle\int_0^1 (\ln x)^n\,dx = (-1)^n\Gamma(n+1), \quad n > 0$

[*Hint:* Let $t = -\ln x$.]

(b) $\displaystyle\int_0^{+\infty} e^{-x^n}\,dx = \Gamma\left(\frac{n+1}{n}\right), \quad n > 0.$

[*Hint:* Let $t = x^n$. Use the result in Exercise 3(b).]

C **5.** A ***simple pendulum*** consists of a mass that swings in a vertical plane at the end of a massless rod of length $L$, as shown in the accompanying figure. Suppose that a simple pendulum is displaced through an angle $\theta_0$ and released from rest. It can be

shown that in the absence of friction, the time $T$ required for the pendulum to make one complete back-and-forth swing, called the ***period***, is given by

$$T = \sqrt{\frac{8L}{g}} \int_0^{\theta_0} \frac{1}{\sqrt{\cos\theta - \cos\theta_0}}\, d\theta \qquad (1)$$

where $\theta = \theta(t)$ is the angle the pendulum makes with the vertical at time $t$. The improper integral in (1) is difficult to evaluate numerically. By a substitution outlined below it can be shown that the period can be expressed as

$$T = 4\sqrt{\frac{L}{g}} \int_0^{\pi/2} \frac{1}{\sqrt{1 - k^2 \sin^2\phi}}\, d\phi \qquad (2)$$

where $k = \sin(\theta_0/2)$. The integral in (2) is called a ***complete elliptic integral of the first kind*** and is more easily evaluated by numerical methods.

(a) Obtain (2) from (1) by substituting

$$\cos\theta = 1 - 2\sin^2(\theta/2)$$
$$\cos\theta_0 = 1 - 2\sin^2(\theta_0/2)$$
$$k = \sin(\theta_0/2)$$

and then making the change of variable

$$\sin\phi = \frac{\sin(\theta/2)}{\sin(\theta_0/2)} = \frac{\sin(\theta/2)}{k}$$

(b) Use (2) and the numerical integration capability of your CAS to estimate the period of a simple pendulum for which $L = 1.5$ ft, $\theta_0 = 20°$, and $g = 32$ ft/s$^2$.

# 8 MATHEMATICAL MODELING WITH DIFFERENTIAL EQUATIONS

*In the 1920s, excavation of an archeological site in Folsom, New Mexico, uncovered a collection of prehistoric stone spearheads now known as "Folsom points." In 1950, carbon dating of charred bison bones found nearby confirmed that human hunters lived in the area between 9000 B.C. and 8000 B.C. We will study carbon dating in this chapter.*

Many fundamental laws of science and engineering can be expressed in terms of differential equations. We introduced the concept of a differential equation in Section 5.2, but in this chapter we will go into more detail. We will discuss some important mathematical models that involve differential equations, and we will discuss some methods for solving and approximating solutions of some of the basic types of differential equations. However, we will only be able to touch the surface of this topic, leaving many important topics in differential equations to courses that are devoted completely to the subject.

## 8.1 MODELING WITH DIFFERENTIAL EQUATIONS

*In this section we will introduce some basic terminology and concepts concerning differential equations. We will also discuss the general idea of modeling with differential equations, and we will encounter important models that can be applied to demography, medicine, ecology, and physics. In later sections of this chapter we will investigate methods that may be used to solve these differential equations.*

### TERMINOLOGY

Recall from Section 5.2 that a ***differential equation*** is an equation involving one or more derivatives of an unknown function. In this section we will denote the unknown function by $y = y(x)$ unless the differential equation arises from an applied problem involving time, in which case we will denote it by $y = y(t)$. The ***order*** of a differential equation is the order of the highest derivative that it contains. Some examples are given in Table 8.1.1. The last two equations in that table are expressed in "prime" notation, which does not specify the independent variable explicitly. However, you will usually be able to tell from the equation itself or from the context in which it arises whether to interpret $y'$ as $dy/dx$ or $dy/dt$.

**Table 8.1.1**

| DIFFERENTIAL EQUATION | ORDER |
|---|---|
| $\frac{dy}{dx} = 3y$ | 1 |
| $\frac{d^2y}{dx^2} - 6\frac{dy}{dx} + 8y = 0$ | 2 |
| $\frac{d^3y}{dt^3} - t\frac{dy}{dt} + (t^2 - 1)y = e^t$ | 3 |
| $y' - y = e^{2x}$ | 1 |
| $y'' + y' = \cos t$ | 2 |

### SOLUTIONS OF DIFFERENTIAL EQUATIONS

A function $y = y(x)$ is a ***solution*** of a differential equation on an open interval if the equation is satisfied identically on the interval when $y$ and its derivatives are substituted

into the equation. For example, $y = e^{2x}$ is a solution of the differential equation

$$\frac{dy}{dx} - y = e^{2x} \tag{1}$$

on the interval $(-\infty, +\infty)$, since substituting $y$ and its derivative into the left side of this equation yields

$$\frac{dy}{dx} - y = \frac{d}{dx}[e^{2x}] - e^{2x} = 2e^{2x} - e^{2x} = e^{2x}$$

for all real values of $x$. However, this is not the only solution on $(-\infty, +\infty)$; for example, the function

$$y = e^{2x} + Ce^{x} \tag{2}$$

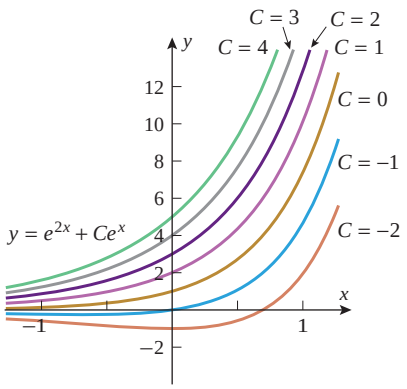
is also a solution for every real value of the constant $C$, since

$$\frac{dy}{dx} - y = \frac{d}{dx}[e^{2x} + Ce^{x}] - (e^{2x} + Ce^{x}) = (2e^{2x} + Ce^{x}) - (e^{2x} + Ce^{x}) = e^{2x}$$

After developing some techniques for solving equations such as (1), we will be able to show that *all* solutions of (1) on $(-\infty, +\infty)$ can be obtained by substituting values for the constant $C$ in (2). On a given interval, a solution of a differential equation from which all solutions on that interval can be derived by substituting values for arbitrary constants is called a ***general solution*** of the equation on the interval. Thus (2) is a general solution of (1) on the interval $(-\infty, +\infty)$.

The first-order equation (1) has a single arbitrary constant in its general solution (2). Usually, the general solution of an $n$th-order differential equation will contain $n$ arbitrary constants. This is plausible, since $n$ integrations are needed to recover a function from its $n$th derivative.

The graph of a solution of a differential equation is called an ***integral curve*** for the equation, so the general solution of a differential equation produces a family of integral curves corresponding to the different possible choices for the arbitrary constants. For example, Figure 8.1.1 shows some integral curves for (1), which were obtained by assigning values to the arbitrary constant in (2).



Integral curves for $\frac{dy}{dx} - y = e^{2x}$

▶ **Figure 8.1.1**

## INITIAL-VALUE PROBLEMS

When an applied problem leads to a differential equation, there are usually conditions in the problem that determine specific values for the arbitrary constants. As a rule of thumb, it requires $n$ conditions to determine values for all $n$ arbitrary constants in the general solution of an $n$th-order differential equation (one condition for each constant). For a first-order equation, the single arbitrary constant can be determined by specifying the value of the unknown function $y(x)$ at an arbitrary $x$-value $x_0$, say $y(x_0) = y_0$. This is called an ***initial condition***, and the problem of solving a first-order equation subject to an initial condition is called a ***first-order initial-value problem***. Geometrically, the initial condition $y(x_0) = y_0$ has the effect of isolating the integral curve that passes through the point $(x_0, y_0)$ from the complete family of integral curves.

► **Example 1** The solution of the initial-value problem

$$\frac{dy}{dx} - y = e^{2x}, \quad y(0) = 3$$

can be obtained by substituting the initial condition $x = 0$, $y = 3$ in the general solution (2) to find $C$. We obtain

$$3 = e^0 + Ce^0 = 1 + C$$

Thus, $C = 2$, and the solution of the initial-value problem, which is obtained by substituting this value of $C$ in (2), is

$$y = e^{2x} + 2e^x$$

Geometrically, this solution is realized as the integral curve in Figure 8.1.1 that passes through the point $(0, 3)$. ◄

Since many important principles in the physical and social sciences involve rates of change, it should not be surprising that such principles can often be modeled by differential equations. Here are some examples of the modeling process.

## UNINHIBITED POPULATION GROWTH

© AndreasReh/iStockphoto

*When the number of bacteria is small, an uninhibited population growth model can be used to model the growth of bacteria in a petri dish.*

One of the simplest models of population growth is based on the observation that when populations (people, plants, bacteria, and fruit flies, for example) are not constrained by environmental limitations, they tend to grow at a rate that is proportional to the size of the population—the larger the population, the more rapidly it grows.

To translate this principle into a mathematical model, suppose that $y = y(t)$ denotes the population at time $t$. At each point in time, the rate of increase of the population with respect to time is $dy/dt$, so the assumption that the rate of growth is proportional to the population is described by the differential equation

$$\frac{dy}{dt} = ky \tag{3}$$

where $k$ is a positive constant of proportionality that can usually be determined experimentally. Thus, if the population is known at some point in time, say $y = y_0$ at time $t = 0$, then a formula for the population $y(t)$ can be obtained by solving the initial-value problem

$$\frac{dy}{dt} = ky, \quad y(0) = y_0$$

## INHIBITED POPULATION GROWTH; LOGISTIC MODELS

The uninhibited population growth model was predicated on the assumption that the population $y = y(t)$ was not constrained by the environment. While this assumption is reasonable as long as the size of the population is relatively small, environmental effects become increasingly important as the population grows. In general, populations grow within ecological systems that can only support a certain number of individuals; the number $L$ of such individuals is called the ***carrying capacity*** of the system. When $y > L$, the population exceeds the capacity of the ecological system and tends to decrease toward $L$; when $y < L$, the population is below the capacity of the ecological system and tends to increase toward $L$; when $y = L$, the population is in balance with the capacity of the ecological system and tends to remain stable.

To translate this into a mathematical model, we must look for a differential equation in which $y > 0$, $L > 0$, and

$$\frac{dy}{dt} < 0 \quad \text{if} \quad \frac{y}{L} > 1, \qquad \frac{dy}{dt} > 0 \quad \text{if} \quad \frac{y}{L} < 1, \qquad \frac{dy}{dt} = 0 \quad \text{if} \quad \frac{y}{L} = 1$$

Moreover, when the population is far below the carrying capacity (i.e., $y/L \approx 0$), then the environmental constraints should have little effect, and the growth rate should behave like the uninhibited population model. Thus, we want

$$\frac{dy}{dt} \approx ky \quad \text{if} \quad \frac{y}{L} \approx 0$$

A simple differential equation that meets all of these requirements is

$$\frac{dy}{dt} = k\left(1 - \frac{y}{L}\right) y$$

where $k$ is a positive constant of proportionality. Thus if $k$ and $L$ can be determined experimentally, and if the population is known at some point, say $y(0) = y_0$, then a formula for the population $y(t)$ can be determined by solving the initial-value problem

$$\frac{dy}{dt} = k\left(1 - \frac{y}{L}\right) y, \quad y(0) = y_0 \tag{4}$$

This theory of population growth is due to the Belgian mathematician P. F. Verhulst (1804–1849), who introduced it in 1838 and described it as "logistic growth."* Thus, the differential equation in (4) is called the ***logistic differential equation***, and the growth model described by (4) is called the ***logistic model***.

## PHARMACOLOGY

When a drug (say, penicillin or aspirin) is administered to an individual, it enters the bloodstream and then is absorbed by the body over time. Medical research has shown that the amount of a drug that is present in the bloodstream tends to decrease at a rate that is proportional to the amount of the drug present—the more of the drug that is present in the bloodstream, the more rapidly it is absorbed by the body.

To translate this principle into a mathematical model, suppose that $y = y(t)$ is the amount of the drug present in the bloodstream at time $t$. At each point in time, the rate of change in $y$ with respect to $t$ is $dy/dt$, so the assumption that the rate of decrease is proportional to the amount $y$ in the bloodstream translates into the differential equation

$$\frac{dy}{dt} = -ky \tag{5}$$

where $k$ is a positive constant of proportionality that depends on the drug and can be determined experimentally. The negative sign is required because $y$ decreases with time. Thus, if the initial dosage of the drug is known, say $y = y_0$ at time $t = 0$, then a formula for $y(t)$ can be obtained by solving the initial-value problem

$$\frac{dy}{dt} = -ky, \quad y(0) = y_0$$

## SPREAD OF DISEASE

Suppose that a disease begins to spread in a population of $L$ individuals. Logic suggests that at each point in time the rate at which the disease spreads will depend on how many individuals are already affected and how many are not—as more individuals are affected, the opportunity to spread the disease tends to increase, but at the same time there are fewer individuals who are not affected, so the opportunity to spread the disease tends to decrease. Thus, there are two conflicting influences on the rate at which the disease spreads.

*Verhulst's model fell into obscurity for nearly a hundred years because he did not have sufficient census data to test its validity. However, interest in the model was revived during the 1930s when biologists used it successfully to describe the growth of fruit fly and flour beetle populations. Verhulst himself used the model to predict that an upper limit of Belgium's population would be approximately 9,400,000. In 2006 the population was about 10,379,000.

To translate this into a mathematical model, suppose that $y = y(t)$ is the number of individuals who have the disease at time $t$, so of necessity the number of individuals who do not have the disease at time $t$ is $L - y$. As the value of $y$ increases, the value of $L - y$ decreases, so the conflicting influences of the two factors on the rate of spread $dy/dt$ are taken into account by the differential equation

$$\frac{dy}{dt} = ky(L - y)$$

Show that the model for the spread of disease can be viewed as a logistic model with constant of proportionality $kL$ by rewriting (6) appropriately.

where $k$ is a positive constant of proportionality that depends on the nature of the disease and the behavior patterns of the individuals and can be determined experimentally. Thus, if the number of affected individuals is known at some point in time, say $y = y_0$ at time $t = 0$, then a formula for $y(t)$ can be obtained by solving the initial-value problem

$$\frac{dy}{dt} = ky(L - y), \quad y(0) = y_0 \tag{6}$$

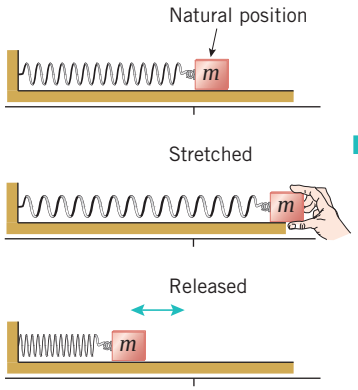
## NEWTON'S LAW OF COOLING

If a hot object is placed into a cool environment, the object will cool at a rate proportional to the difference in temperature between the object and the environment. Similarly, if a cold object is placed into a warm environment, the object will warm at a rate that is again proportional to the difference in temperature between the object and the environment. Together, these observations comprise a result known as *Newton's Law of Cooling*. (Newton's Law of Cooling appeared previously in the exercises of Section 2.2 and was mentioned briefly in Section 5.8.) To translate this into a mathematical model, suppose that $T = T(t)$ is the temperature of the object at time $t$ and that $T_e$ is the temperature of the environment, which is assumed to be constant. Since the rate of change $dT/dt$ is proportional to $T - T_e$, we have

$$\frac{dT}{dt} = k(T - T_e)$$

where $k$ is a constant of proportionality. Moreover, since $dT/dt$ is positive when $T < T_e$, and is negative when $T > T_e$, the sign of $k$ must be *negative*. Thus if the temperature of the object is known at some time, say $T = T_0$ at time $t = 0$, then a formula for the temperature $T(t)$ can be obtained by solving the initial-value problem

$$\frac{dT}{dt} = k(T - T_e), \quad T(0) = T_0 \tag{7}$$



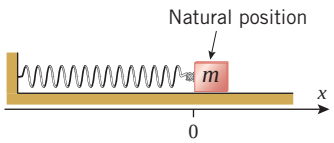
▲ Figure 8.1.2

## VIBRATIONS OF SPRINGS

We conclude this section with an engineering model that leads to a second-order differential equation.

As shown in Figure 8.1.2, consider a block of mass $m$ attached to the end of a horizontal spring. Assume that the block is then set into vibratory motion by pulling the spring beyond its natural position and releasing it at time $t = 0$. We will be interested in finding a mathematical model that describes the vibratory motion of the block over time.

To translate this problem into mathematical form, we introduce a horizontal $x$-axis whose positive direction is to the right and whose origin is at the right end of the spring when the spring is in its natural position (Figure 8.1.3). Our goal is to find a model for the coordinate $x = x(t)$ of the point of attachment of the block to the spring as a function of time. In developing this model, we will assume that the only force on the mass $m$ is the restoring force of the spring, and we will ignore the influence of other forces such as friction, air resistance, and so forth. Recall from Hooke's Law (Section 6.6) that when the connection point has coordinate $x(t)$, the restoring force is $-kx(t)$, where $k$ is the spring constant. [The negative sign is due to the fact that the restoring force is to the left when $x(t)$ is positive, and the restoring force is to the right when $x(t)$ is negative.] It follows from Newton's



▲ Figure 8.1.3

Second Law of Motion [Equation (5) of Section 6.6] that this restoring force is equal to the product of the mass $m$ and the acceleration $d^2x/dt^2$ of the mass. In other words, we have

$$m\frac{d^2x}{dt^2} = -kx$$

which is a second-order differential equation for $x$. If at time $t = 0$ the mass is released from rest at position $x(0) = x_0$, then a formula for $x(t)$ can be found by solving the initial-value problem

$$m\frac{d^2x}{dt^2} = -kx, \quad x(0) = x_0, \quad x'(0) = 0 \tag{8}$$

[If at time $t = 0$ the mass is given an initial velocity $v_0 \neq 0$, then the condition $x'(0) = 0$ must be replaced by $x'(0) = v_0$.]

## ✔ QUICK CHECK EXERCISES 8.1 (See page 568 for answers.)

**1.** Match each differential equation with its family of solutions.

(a) $x\dfrac{dy}{dx} = y$ _____ (i) $y = x^2 + C$

(b) $y'' = 4y$ _____ (ii) $y = C_1 \sin 2x + C_2 \cos 2x$

(c) $\dfrac{dy}{dx} = 2x$ _____ (iii) $y = C_1e^{2x} + C_2e^{-2x}$

(d) $\dfrac{d^2y}{dx^2} = -4y$ _____ (iv) $y = Cx$

**2.** If $y = C_1e^{2x} + C_2xe^{2x}$ is the general solution of a differential equation, then the order of the equation is _____, and a solution to the differential equation that satisfies the initial conditions $y(0) = 1$, $y'(0) = 4$ is given by $y =$ _____.

**3.** The graph of a differentiable function $y = y(x)$ passes through the point $(0, 1)$ and at every point $P(x, y)$ on the graph the tangent line is perpendicular to the line through $P$ and the origin. Find an initial-value problem whose solution is $y(x)$.

**4.** A glass of ice water with a temperature of 36°F is placed in a room with a constant temperature of 68°F. Assuming that Newton's Law of Cooling applies, find an initial-value problem whose solution is the temperature of water $t$ minutes after it is placed in the room. [*Note:* The differential equation will involve a constant of proportionality.]

## EXERCISE SET 8.1

**1.** Confirm that $y = 3e^{x^3}$ is a solution of the initial-value problem $y' = 3x^2y$, $y(0) = 3$.

**2.** Confirm that $y = \frac{1}{4}x^4 + 2\cos x + 1$ is a solution of the initial-value problem $y' = x^3 - 2\sin x$, $y(0) = 3$.

**3–4** State the order of the differential equation, and confirm that the functions in the given family are solutions. ■

**3.** (a) $(1 + x)\dfrac{dy}{dx} = y$; $y = c(1 + x)$

(b) $y'' + y = 0$; $y = c_1 \sin t + c_2 \cos t$

**4.** (a) $2\dfrac{dy}{dx} + y = x - 1$; $y = ce^{-x/2} + x - 3$

(b) $y'' - y = 0$; $y = c_1e^t + c_2e^{-t}$

**5–8 True–False** Determine whether the statement is true or false. Explain your answer. ■

**5.** The equation

$$\left(\frac{dy}{dx}\right)^2 = \frac{dy}{dx} + 2y$$

is an example of a second-order differential equation.

**6.** The differential equation

$$\frac{dy}{dx} = 2y + 1$$

has a solution that is constant.

**7.** We expect the general solution of the differential equation

$$\frac{d^3y}{dx^3} + 3\frac{d^2y}{dx^2} - \frac{dy}{dx} + 4y = 0$$

to involve three arbitrary constants.

**8.** If every solution to a differential equation can be expressed in the form $y = Ae^{x+b}$ for some choice of constants $A$ and $b$, then the differential equation must be of second order.

**9–14** In each part, verify that the functions are solutions of the differential equation by substituting the functions into the equation. ■

**9.** $y'' + y' - 2y = 0$

(a) $e^{-2x}$ and $e^x$

(b) $c_1e^{-2x} + c_2e^x$ ($c_1$, $c_2$ constants)

**10.** $y'' - y' - 6y = 0$
(a) $e^{-2x}$ and $e^{3x}$
(b) $c_1e^{-2x} + c_2e^{3x}$ ($c_1$, $c_2$ constants)

**11.** $y'' - 4y' + 4y = 0$
(a) $e^{2x}$ and $xe^{2x}$
(b) $c_1e^{2x} + c_2xe^{2x}$ ($c_1$, $c_2$ constants)

**12.** $y'' - 8y' + 16y = 0$
(a) $e^{4x}$ and $xe^{4x}$
(b) $c_1e^{4x} + c_2xe^{4x}$ ($c_1$, $c_2$ constants)

**13.** $y'' + 4y = 0$
(a) $\sin 2x$ and $\cos 2x$
(b) $c_1 \sin 2x + c_2 \cos 2x$ ($c_1$, $c_2$ constants)

**14.** $y'' + 4y' + 13y = 0$
(a) $e^{-2x} \sin 3x$ and $e^{-2x} \cos 3x$
(b) $e^{-2x}(c_1 \sin 3x + c_2 \cos 3x)$ ($c_1$, $c_2$ constants)

**15–20** Use the results of Exercises 9–14 to find a solution to the initial-value problem. ■

**15.** $y'' + y' - 2y = 0,\ y(0) = -1,\ y'(0) = -4$

**16.** $y'' - y' - 6y = 0,\ y(0) = 1,\ y'(0) = 8$

**17.** $y'' - 4y' + 4y = 0,\ y(0) = 2,\ y'(0) = 2$

**18.** $y'' - 8y' + 16y = 0,\ y(0) = 1,\ y'(0) = 1$

**19.** $y'' + 4y = 0,\ y(0) = 1,\ y'(0) = 2$

**20.** $y'' + 4y' + 13y = 0,\ y(0) = -1,\ y'(0) = -1$

**21–26** Find a solution to the initial-value problem. ■

**21.** $y' + 4x = 2,\ y(0) = 3$

**22.** $y'' + 6x = 0,\ y(0) = 1,\ y'(0) = 2$

**23.** $y' - y^2 = 0,\ y(1) = 2$ [*Hint:* Assume the solution has an inverse function $x = x(y)$. Find, and solve, a differential equation that involves $x'(y)$.]

**24.** $y' = 1 + y^2,\ y(0) = 0$ (See Exercise 23.)

**25.** $x^2y' + 2xy = 0,\ y(1) = 2$ [*Hint:* Interpret the left-hand side of the equation as the derivative of a product of two functions.]

**26.** $xy' + y = e^x,\ y(1) = 1 + e$ (See Exercise 25.)

## FOCUS ON CONCEPTS

**27.** (a) Suppose that a quantity $y = y(t)$ increases at a rate that is proportional to the square of the amount present, and suppose that at time $t = 0$, the amount present is $y_0$. Find an initial-value problem whose solution is $y(t)$.
(b) Suppose that a quantity $y = y(t)$ decreases at a rate that is proportional to the square of the amount present, and suppose that at a time $t = 0$, the amount present is $y_0$. Find an initial-value problem whose solution is $y(t)$.

**28.** (a) Suppose that a quantity $y = y(t)$ changes in such a way that $dy/dt = k\sqrt{y}$, where $k > 0$. Describe how $y$ changes in words.
(b) Suppose that a quantity $y = y(t)$ changes in such a way that $dy/dt = -ky^3$, where $k > 0$. Describe how $y$ changes in words.

**29.** (a) Suppose that a particle moves along an $s$-axis in such a way that its velocity $v(t)$ is always half of $s(t)$. Find a differential equation whose solution is $s(t)$.
(b) Suppose that an object moves along an $s$-axis in such a way that its acceleration $a(t)$ is always twice the velocity. Find a differential equation whose solution is $s(t)$.

**30.** Suppose that a body moves along an $s$-axis through a resistive medium in such a way that the velocity $v = v(t)$ decreases at a rate that is twice the square of the velocity.
(a) Find a differential equation whose solution is the velocity $v(t)$.
(b) Find a differential equation whose solution is the position $s(t)$.

**31.** Consider a solution $y = y(t)$ to the uninhibited population growth model.
(a) Use Equation (3) to explain why $y$ will be an increasing function of $t$.
(b) Use Equation (3) to explain why the graph $y = y(t)$ will be concave up.

**32.** Consider the logistic model for population growth.
(a) Explain why there are two constant solutions to this model.
(b) For what size of the population will the population be growing most rapidly?

**33.** Consider the model for the spread of disease.
(a) Explain why there are two constant solutions to this model.
(b) For what size of the infected population is the disease spreading most rapidly?

**34.** Explain why there is exactly one constant solution to the Newton's Law of Cooling model.

**35.** Show that if $c_1$ and $c_2$ are any constants, the function

$$x = x(t) = c_1 \cos\left(\sqrt{\frac{k}{m}}\, t\right) + c_2 \sin\left(\sqrt{\frac{k}{m}}\, t\right)$$

is a solution to the differential equation for the vibrating spring. (The corresponding motion of the spring is referred to as ***simple harmonic motion***.)

**36.** (a) Use the result of Exercise 35 to solve the initial-value problem in (8).
(b) Find the amplitude, period, and frequency of your answer to part (a), and interpret each of these in terms of the motion of the spring.

**37.** **Writing** Select one of the models in this section and write a paragraph that discusses conditions under which the model would not be appropriate. How might you modify the model to take those conditions into account?

## ✔ QUICK CHECK ANSWERS 8.1

1. (a) (iv) (b) (iii) (c) (i) (d) (ii) 2. 2; $e^{2x} + 2xe^{2x}$ 3. $\dfrac{dy}{dx} = -\dfrac{x}{y}$, $y(0) = 1$ 4. $\dfrac{dT}{dt} = k(T - 68)$, $T(0) = 36$

# 8.2 SEPARATION OF VARIABLES

*In this section we will discuss a method, called "separation of variables," that can be used to solve a large class of first-order differential equations of a particular form. We will use this method to investigate mathematical models for exponential growth and decay, including population models and carbon dating.*

## FIRST-ORDER SEPARABLE EQUATIONS

We will now consider a method of solution that can often be applied to first-order equations that are expressible in the form

$$h(y)\frac{dy}{dx} = g(x) \tag{1}$$

Some writers define a separable equation to be one that can be written in the form $dy/dx = G(x)H(y)$. Explain why this is equivalent to our definition.

Such first-order equations are said to be ***separable***. Some examples of separable equations are given in Table 8.2.1. The name "separable" arises from the fact that Equation (1) can be rewritten in the differential form

$$h(y)\,dy = g(x)\,dx \tag{2}$$

in which the expressions involving $x$ and $y$ appear on opposite sides. The process of rewriting (1) in form (2) is called ***separating variables***.

**Table 8.2.1**

| EQUATION | FORM (1) | $h(y)$ | $g(x)$ |
|---|---|---|---|
| $\dfrac{dy}{dx} = \dfrac{x}{y}$ | $y\dfrac{dy}{dx} = x$ | $y$ | $x$ |
| $\dfrac{dy}{dx} = x^2y^3$ | $\dfrac{1}{y^3}\dfrac{dy}{dx} = x^2$ | $\dfrac{1}{y^3}$ | $x^2$ |
| $\dfrac{dy}{dx} = y$ | $\dfrac{1}{y}\dfrac{dy}{dx} = 1$ | $\dfrac{1}{y}$ | $1$ |
| $\dfrac{dy}{dx} = y - \dfrac{y}{x}$ | $\dfrac{1}{y}\dfrac{dy}{dx} = 1 - \dfrac{1}{x}$ | $\dfrac{1}{y}$ | $1 - \dfrac{1}{x}$ |

To motivate a method for solving separable equations, assume that $h(y)$ and $g(x)$ are continuous functions of their respective variables, and let $H(y)$ and $G(x)$ denote antiderivatives of $h(y)$ and $g(x)$, respectively. Consider the equation that results if we integrate both sides of (2), the left side with respect to $y$ and the right side with respect to $x$. We then have

$$\int h(y)\,dy = \int g(x)\,dx \tag{3}$$

or, equivalently,

$$H(y) = G(x) + C \tag{4}$$

where $C$ denotes a constant. We claim that a differentiable function $y = y(x)$ is a solution to (1) if and only if $y$ satisfies Equation (4) for some choice of the constant $C$.

Suppose that $y = y(x)$ is a solution to (1). It then follows from the chain rule that

$$\frac{d}{dx}[H(y)] = \frac{dH}{dy}\frac{dy}{dx} = h(y)\frac{dy}{dx} = g(x) = \frac{dG}{dx} \tag{5}$$

Since the functions $H(y)$ and $G(x)$ have the same derivative with respect to $x$, they must differ by a constant (Theorem 4.8.3). It then follows that $y$ satisfies (4) for an appropriate choice of $C$. Conversely, if $y = y(x)$ is defined implicitly by Equation (4), then implicit differentiation shows that (5) is satisfied, and thus $y(x)$ is a solution to (1) (Exercise 67). Because of this, it is common practice to refer to Equation (4) as the "solution" to (1).

In summary, we have the following procedure for solving (1), called ***separation of variables***:

***Separation of Variables***

**Step 1.** Separate the variables in (1) by rewriting the equation in the differential form

$$h(y)\,dy = g(x)\,dx$$

**Step 2.** Integrate both sides of the equation in Step 1 (the left side with respect to $y$ and the right side with respect to $x$):

$$\int h(y)\,dy = \int g(x)\,dx$$

**Step 3.** If $H(y)$ is any antiderivative of $h(y)$ and $G(x)$ is any antiderivative of $g(x)$, then the equation

$$H(y) = G(x) + C$$

will generally define a family of solutions implicitly. In some cases it may be possible to solve this equation explicitly for $y$.

▶ **Example 1** Solve the differential equation

$$\frac{dy}{dx} = -4xy^2$$

and then solve the initial-value problem

$$\frac{dy}{dx} = -4xy^2, \quad y(0) = 1$$

For an initial-value problem in which the differential equation is separable, you can either use the initial condition to solve for $C$, as in Example 1, or replace the indefinite integrals in Step 2 by definite integrals (Exercise 68).

***Solution.*** For $y \neq 0$ we can write the differential equation in form (1) as

$$\frac{1}{y^2}\frac{dy}{dx} = -4x$$

Separating variables and integrating yields

$$\frac{1}{y^2}\,dy = -4x\,dx$$

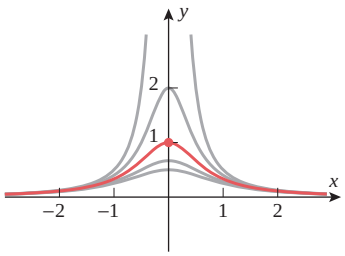
$$\int \frac{1}{y^2}\,dy = \int -4x\,dx$$

or

$$-\frac{1}{y} = -2x^2 + C$$

Solving for $y$ as a function of $x$, we obtain

$$y = \frac{1}{2x^2 - C}$$



Integral curves for $\dfrac{dy}{dx} = -4xy^2$

▲ Figure 8.2.1

The initial condition $y(0) = 1$ requires that $y = 1$ when $x = 0$. Substituting these values into our solution yields $C = -1$ (verify). Thus, a solution to the initial-value problem is

$$y = \frac{1}{2x^2 + 1} \tag{6}$$

Some integral curves and our solution of the initial-value problem are graphed in Figure 8.2.1. ◄

One aspect of our solution to Example 1 deserves special comment. Had the initial condition been $y(0) = 0$ instead of $y(0) = 1$, the method we used would have failed to yield a solution to the resulting initial-value problem (Exercise 25). This is due to the fact that we assumed $y \neq 0$ in order to rewrite the equation $dy/dx = -4xy^2$ in the form

$$\frac{1}{y^2}\frac{dy}{dx} = -4x$$

It is important to be aware of such assumptions when manipulating a differential equation algebraically.

► **Example 2** Solve the initial-value problem

$$(4y - \cos y)\frac{dy}{dx} - 3x^2 = 0, \quad y(0) = 0$$

***Solution.*** We can write the differential equation in form (1) as

$$(4y - \cos y)\frac{dy}{dx} = 3x^2$$

Separating variables and integrating yields

$$(4y - \cos y)\,dy = 3x^2\,dx$$

$$\int (4y - \cos y)\,dy = \int 3x^2\,dx$$

or

$$2y^2 - \sin y = x^3 + C \tag{7}$$

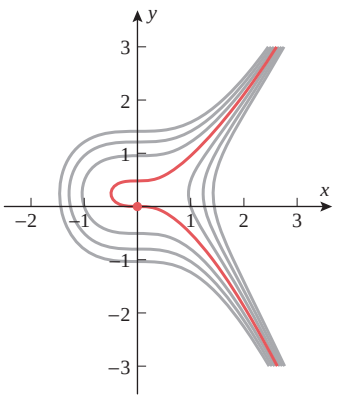
For the initial-value problem, the initial condition $y(0) = 0$ requires that $y = 0$ if $x = 0$. Substituting these values into (7) to determine the constant of integration yields $C = 0$ (verify). Thus, the solution of the initial-value problem is

$$2y^2 - \sin y = x^3$$

or

$$x = \sqrt[3]{2y^2 - \sin y} \quad \blacktriangleleft \tag{8}$$

The solution of an initial-value problem in $x$ and $y$ can sometimes be expressed explicitly as a function of $x$ [as in Formula (6) of Example 1], or explicitly as a function of $y$ [as in Formula (8) of Example 2]. However, sometimes the solution cannot be expressed in either such form, so the only option is to express it implicitly as an equation in $x$ and $y$.



Integral curves for $(4y - \cos y)\dfrac{dy}{dx} - 3x^2 = 0$

▲ Figure 8.2.2

Some integral curves and the solution of the initial-value problem in Example 2 are graphed in Figure 8.2.2.

Initial-value problems often result from geometrical questions, as in the following example.

► **Example 3** Find a curve in the $xy$-plane that passes through $(0, 3)$ and whose tangent line at a point $(x, y)$ has slope $2x/y^2$.

**TECHNOLOGY MASTERY**

Some computer algebra systems can graph implicit equations. Figure 8.2.2 shows the graphs of (7) for $C = 0, \pm 1, \pm 2$, and $\pm 3$. If you have a CAS that can graph implicit equations, try to duplicate this figure.

***Solution.*** Since the slope of the tangent line is $dy/dx$, we have

$$\frac{dy}{dx} = \frac{2x}{y^2} \tag{9}$$

and, since the curve passes through (0, 3), we have the initial condition

$$y(0) = 3$$

Equation (9) is separable and can be written as

$$y^2\,dy = 2x\,dx$$

so

$$\int y^2\,dy = \int 2x\,dx \quad \text{or} \quad \tfrac{1}{3}y^3 = x^2 + C$$

It follows from the initial condition that $y = 3$ if $x = 0$. Substituting these values into the last equation yields $C = 9$ (verify), so the equation of the desired curve is

$$\tfrac{1}{3}y^3 = x^2 + 9 \quad \text{or} \quad y = (3x^2 + 27)^{1/3} \quad \blacktriangleleft$$

## EXPONENTIAL GROWTH AND DECAY MODELS

The population growth and pharmacology models developed in Section 8.1 are examples of a general class of models called *exponential models*. In general, exponential models arise in situations where a quantity increases or decreases at a rate that is proportional to the amount of the quantity present. More precisely, we make the following definition.

**8.2.1 DEFINITION** A quantity $y = y(t)$ is said to have an ***exponential growth model*** if it increases at a rate that is proportional to the amount of the quantity present, and it is said to have an ***exponential decay model*** if it decreases at a rate that is proportional to the amount of the quantity present. Thus, for an exponential growth model, the quantity $y(t)$ satisfies an equation of the form

$$\frac{dy}{dt} = ky \quad (k > 0) \tag{10}$$

and for an exponential decay model, the quantity $y(t)$ satisfies an equation of the form

$$\frac{dy}{dt} = -ky \quad (k > 0) \tag{11}$$

The constant $k$ is called the ***growth constant*** or the ***decay constant***, as appropriate.

Equations (10) and (11) are separable since they have the form of (1), but with $t$ rather than $x$ as the independent variable. To illustrate how these equations can be solved, suppose that a positive quantity $y = y(t)$ has an exponential growth model and that we know the amount of the quantity at some point in time, say $y = y_0$ when $t = 0$. Thus, a formula for $y(t)$ can be obtained by solving the initial-value problem

$$\frac{dy}{dt} = ky, \quad y(0) = y_0$$

Separating variables and integrating yields

$$\int \frac{1}{y}\,dy = \int k\,dt$$

or (since $y > 0$)

$$\ln y = kt + C \tag{12}$$

The initial condition implies that $y = y_0$ when $t = 0$. Substituting these values in (12) yields $C = \ln y_0$ (verify). Thus,

$$\ln y = kt + \ln y_0$$

from which it follows that

$$y = e^{\ln y} = e^{kt + \ln y_0}$$

or, equivalently,

$$y = y_0 e^{kt} \tag{13}$$

We leave it for you to show that if $y = y(t)$ has an exponential decay model, and if $y(0) = y_0$, then

$$y = y_0 e^{-kt} \tag{14}$$

## INTERPRETING THE GROWTH AND DECAY CONSTANTS

The significance of the constant $k$ in Formulas (13) and (14) can be understood by reexamining the differential equations that gave rise to these formulas. For example, in the case of the exponential growth model, Equation (10) can be rewritten as

$$k = \frac{dy/dt}{y} \tag{15}$$

It is standard practice in applications to call (15) the *growth rate*, even though it is misleading (the growth rate is $dy/dt$). However, the practice is so common that we will follow it here.

which states that the growth rate as a fraction of the entire population remains constant over time, and this constant is $k$. For this reason, $k$ is called the ***relative growth rate*** of the population. It is usual to express the relative growth rate as a percentage. Thus, a relative growth rate of 3% per unit of time in an exponential growth model means that $k = 0.03$. Similarly, the constant $k$ in an exponential decay model is called the ***relative decay rate***.

▶ **Example 4** According to the U.S. Census Bureau, the world population in 2011 was 6.9 billion and growing at a rate of about 1.10% per year. Assuming an exponential growth model, estimate the world population at the beginning of the year 2030.

***Solution.*** We assume that the population at the beginning of 2011 was 6.9 billion and let

$t$ = time elapsed from the beginning of 2011 (in years)

$y$ = world population (in billions)

Since the beginning of 2011 corresponds to $t = 0$, it follows from the given data that

$$y_0 = y(0) = 6.9 \text{ billion}$$

Since the growth rate is 1.10% ($k = 0.011$), it follows from (13) that the world population at time $t$ will be

$$y(t) = y_0 e^{kt} = 6.9e^{0.011t} \tag{16}$$

In Example 4 the growth rate was given, so there was no need to calculate it. If the growth rate or decay rate is unknown, then it can be calculated using the initial condition and the value of $y$ at another point in time (Exercise 44).

Since the beginning of the year 2030 corresponds to an elapsed time of $t = 19$ years ($2030 - 2011 = 19$), it follows from (16) that the world population by the year 2030 will be

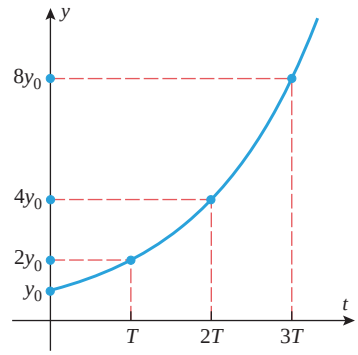
$$y(19) = 6.9e^{0.011(19)} \approx 8.5$$

which is a population of approximately 8.5 billion. ◀

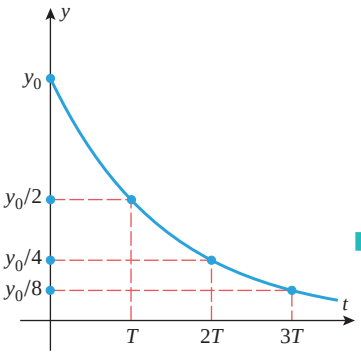
## DOUBLING TIME AND HALF-LIFE

If a quantity $y$ has an exponential growth model, then the time required for the original size to double is called the ***doubling time***, and if $y$ has an exponential decay model, then the time required for the original size to reduce by half is called the ***half-life***. As it turns out, doubling time and half-life depend only on the growth or decay rate and not on the amount present initially. To see why this is so, suppose that $y = y(t)$ has an exponential growth model

$$y = y_0 e^{kt} \tag{17}$$



Exponential growth model with doubling time $T$



Exponential decay model with half-life $T$

▲ **Figure 8.2.3**

and let $T$ denote the amount of time required for $y$ to double in size. Thus, at time $t = T$ the value of $y$ will be $2y_0$, and hence from (17)

$$2y_0 = y_0 e^{kT} \quad \text{or} \quad e^{kT} = 2$$

Taking the natural logarithm of both sides yields $kT = \ln 2$, which implies that the doubling time is

$$T = \frac{1}{k} \ln 2 \tag{18}$$

We leave it as an exercise to show that Formula (18) also gives the half-life of an exponential decay model. Observe that this formula does not involve the initial amount $y_0$, so that in an exponential growth or decay model, the quantity $y$ doubles (or reduces by half) every $T$ units (Figure 8.2.3).

▶ **Example 5** It follows from (18) that with a continued growth rate of 1.10% per year, the doubling time for the world population will be

$$T = \frac{1}{0.011} \ln 2 \approx 63$$

or approximately 63 years. Thus, with a continued 1.10% annual growth rate the population of 6.9 billion in 2011 will double to 13.8 billion by the year 2074 and will double again to 27.6 billion by 2137. ◀

## RADIOACTIVE DECAY

It is a fact of physics that radioactive elements disintegrate spontaneously in a process called ***radioactive decay***. Experimentation has shown that the rate of disintegration is proportional to the amount of the element present, which implies that the amount $y = y(t)$ of a radioactive element present as a function of time has an exponential decay model.

Every radioactive element has a specific half-life; for example, the half-life of radioactive carbon-14 is about 5730 years. Thus, from (18), the decay constant for this element is

$$k = \frac{1}{T} \ln 2 = \frac{\ln 2}{5730} \approx 0.000121$$

and this implies that if there are $y_0$ units of carbon-14 present at time $t = 0$, then the number of units present after $t$ years will be approximately

$$y(t) = y_0 e^{-0.000121t} \tag{19}$$

▶ **Example 6** If 100 grams of radioactive carbon-14 are stored in a cave for 1000 years, how many grams will be left at that time?

***Solution.*** From (19) with $y_0 = 100$ and $t = 1000$, we obtain

$$y(1000) = 100e^{-0.000121(1000)} = 100e^{-0.121} \approx 88.6$$

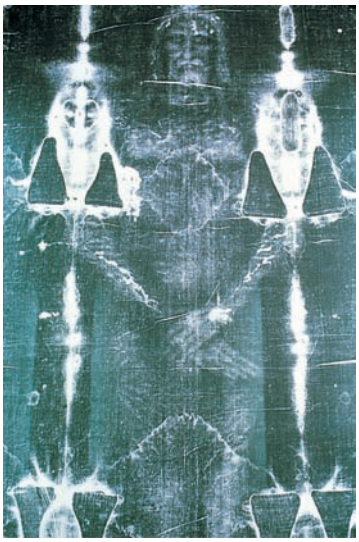
Thus, about 88.6 grams will be left. ◀

## CARBON DATING

When the nitrogen in the Earth's upper atmosphere is bombarded by cosmic radiation, the radioactive element carbon-14 is produced. This carbon-14 combines with oxygen to form carbon dioxide, which is ingested by plants, which in turn are eaten by animals. In this way all living plants and animals absorb quantities of radioactive carbon-14. In 1947 the American nuclear scientist W. F. Libby* proposed the theory that the percentage of

*W. F. Libby, "Radiocarbon Dating," *American Scientist*, Vol. 44, 1956, pp. 98–112.

carbon-14 in the atmosphere and in living tissues of plants is the same. When a plant or animal dies, the carbon-14 in the tissue begins to decay. Thus, the age of an artifact that contains plant or animal material can be estimated by determining what percentage of its original carbon-14 content remains. Various procedures, called ***carbon dating*** or ***carbon-14 dating***, have been developed for measuring this percentage.



Patrick Mesner/Liaison Agency, Inc./Getty Images
*The Shroud of Turin*

▶ **Example 7** In 1988 the Vatican authorized the British Museum to date a cloth relic known as the Shroud of Turin, possibly the burial shroud of Jesus of Nazareth. This cloth, which first surfaced in 1356, contains the negative image of a human body that was widely believed to be that of Jesus. The report of the British Museum showed that the fibers in the cloth contained between 92% and 93% of their original carbon-14. Use this information to estimate the age of the shroud.

***Solution.*** From (19), the fraction of the original carbon-14 that remains after $t$ years is

$$\frac{y(t)}{y_0} = e^{-0.000121t}$$

Taking the natural logarithm of both sides and solving for $t$, we obtain

$$t = -\frac{1}{0.000121} \ln\left(\frac{y(t)}{y_0}\right)$$

Thus, taking $y(t)/y_0$ to be 0.93 and 0.92, we obtain

$$t = -\frac{1}{0.000121} \ln(0.93) \approx 600$$

$$t = -\frac{1}{0.000121} \ln(0.92) \approx 689$$

This means that when the test was done in 1988, the shroud was between 600 and 689 years old, thereby placing its origin between 1299 A.D. and 1388 A.D. Thus, if one accepts the validity of carbon-14 dating, the Shroud of Turin cannot be the burial shroud of Jesus of Nazareth. ◀

## ✔ QUICK CHECK EXERCISES 8.2 (See page 579 for answers.)

**1.** Solve the first-order separable equation

$$h(y)\frac{dy}{dx} = g(x)$$

by completing the following steps:

Step 1. Separate the variables by writing the equation in the differential form _____.

Step 2. Integrate both sides of the equation in Step 1: _____.

Step 3. If $H(y)$ is any antiderivative of $h(y)$, $G(x)$ is any antiderivative of $g(x)$, and $C$ is an unspecified constant, then, as suggested by Step 2, the equation _____ will generally define a family of solutions to $h(y)\,dy/dx = g(x)$ implicitly.

**2.** Suppose that a quantity $y = y(t)$ has an exponential growth model with growth constant $k > 0$.

(a) $y(t)$ satisfies a first-order differential equation of the form $dy/dt =$ _____.

(b) In terms of $k$, the doubling time of the quantity is _____.

(c) If $y_0 = y(0)$ is the initial amount of the quantity, then an explicit formula for $y(t)$ is given by $y(t) =$ _____.

**3.** Suppose that a quantity $y = y(t)$ has an exponential decay model with decay constant $k > 0$.

(a) $y(t)$ satisfies a first-order differential equation of the form $dy/dt =$ _____.

(b) In terms of $k$, the half-life of the quantity is _____.

(c) If $y_0 = y(0)$ is the initial amount of the quantity, then an explicit formula for $y(t)$ is given by $y(t) =$ _____.

**4.** The initial-value problem

$$\frac{dy}{dx} = -\frac{x}{y}, \quad y(0) = 1$$

has solution $y(x) =$ _____.

## EXERCISE SET 8.2 Graphing Utility CAS

**1–10** Solve the differential equation by separation of variables. Where reasonable, express the family of solutions as explicit functions of $x$.

**1.** $\dfrac{dy}{dx} = \dfrac{y}{x}$

**2.** $\dfrac{dy}{dx} = 2(1 + y^2)x$

**3.** $\dfrac{\sqrt{1+x^2}}{1+y}\dfrac{dy}{dx} = -x$

**4.** $(1 + x^4)\dfrac{dy}{dx} = \dfrac{x^3}{y}$

**5.** $(2 + 2y^2)y' = e^x y$

**6.** $y' = -xy$

**7.** $e^{-y}\sin x - y'\cos^2 x = 0$

**8.** $y' - (1 + x)(1 + y^2) = 0$

**9.** $\dfrac{dy}{dx} - \dfrac{y^2 - y}{\sin x} = 0$

**10.** $y - \dfrac{dy}{dx}\sec x = 0$

**11–14** Solve the initial-value problem by separation of variables.

**11.** $y' = \dfrac{3x^2}{2y + \cos y}, \quad y(0) = \pi$

**12.** $y' - xe^y = 2e^y, \quad y(0) = 0$

**13.** $\dfrac{dy}{dt} = \dfrac{2t + 1}{2y - 2}, \quad y(0) = -1$

**14.** $y'\cosh^2 x - y\cosh 2x = 0, \quad y(0) = 3$

**15.** (a) Sketch some typical integral curves of the differential equation $y' = y/2x$.
(b) Find an equation for the integral curve that passes through the point $(2, 1)$.

**16.** (a) Sketch some typical integral curves of the differential equation $y' = -x/y$.
(b) Find an equation for the integral curve that passes through the point $(3, 4)$.

**17–18** Solve the differential equation and then use a graphing utility to generate five integral curves for the equation.

**17.** $(x^2 + 4)\dfrac{dy}{dx} + xy = 0$

**18.** $(\cos y)y' = \cos x$

**19–20** Solve the differential equation. If you have a CAS with implicit plotting capability, use the CAS to generate five integral curves for the equation.

**19.** $y' = \dfrac{x^2}{1 - y^2}$

**20.** $y' = \dfrac{y}{1 + y^2}$

**21–24 True–False** Determine whether the statement is true or false. Explain your answer.

**21.** Every differential equation of the form $y' = f(y)$ is separable.

**22.** A differential equation of the form

$$h(x)\frac{dy}{dx} = g(y)$$

is not separable.

**23.** If a radioactive element has a half-life of 1 minute, and if a container holds 32 g of the element at 1:00 P.M., then the amount remaining at 1:05 P.M. will be 1 g.

**24.** If a population is growing exponentially, then the time it takes the population to quadruple is independent of the size of the population.

**25.** Suppose that the initial condition in Example 1 had been $y(0) = 0$. Show that none of the solutions generated in Example 1 satisfy this initial condition, and then solve the initial-value problem

$$\frac{dy}{dx} = -4xy^2, \quad y(0) = 0$$

Why does the method of Example 1 fail to produce this particular solution?

**26.** Find all ordered pairs $(x_0, y_0)$ such that if the initial condition in Example 1 is replaced by $y(x_0) = y_0$, the solution of the resulting initial-value problem is defined for all real numbers.

**27.** Find an equation of a curve with $x$-intercept 2 whose tangent line at any point $(x, y)$ has slope $xe^{-y}$.

**28.** Use a graphing utility to generate a curve that passes through the point $(1, 1)$ and whose tangent line at $(x, y)$ is perpendicular to the line through $(x, y)$ with slope $-2y/(3x^2)$.

**29.** Suppose that an initial population of 10,000 bacteria grows exponentially at a rate of 2% per hour and that $y = y(t)$ is the number of bacteria present $t$ hours later.
(a) Find an initial-value problem whose solution is $y(t)$.
(b) Find a formula for $y(t)$.
(c) How long does it take for the initial population of bacteria to double?
(d) How long does it take for the population of bacteria to reach 45,000?

**30.** A cell of the bacterium *E. coli* divides into two cells every 20 minutes when placed in a nutrient culture. Let $y = y(t)$ be the number of cells that are present $t$ minutes after a single cell is placed in the culture. Assume that the growth of the bacteria is approximated by an exponential growth model.
(a) Find an initial-value problem whose solution is $y(t)$.
(b) Find a formula for $y(t)$. *(cont.)*

(c) How many cells are present after 2 hours?
(d) How long does it take for the number of cells to reach 1,000,000?

**31.** Radon-222 is a radioactive gas with a half-life of 3.83 days. This gas is a health hazard because it tends to get trapped in the basements of houses, and many health officials suggest that homeowners seal their basements to prevent entry of the gas. Assume that $5.0 \times 10^7$ radon atoms are trapped in a basement at the time it is sealed and that $y(t)$ is the number of atoms present $t$ days later.
(a) Find an initial-value problem whose solution is $y(t)$.
(b) Find a formula for $y(t)$.
(c) How many atoms will be present after 30 days?
(d) How long will it take for 90% of the original quantity of gas to decay?

**32.** Polonium-210 is a radioactive element with a half-life of 140 days. Assume that 10 milligrams of the element are placed in a lead container and that $y(t)$ is the number of milligrams present $t$ days later.
(a) Find an initial-value problem whose solution is $y(t)$.
(b) Find a formula for $y(t)$.
(c) How many milligrams will be present after 10 weeks?
(d) How long will it take for 70% of the original sample to decay?

**33.** Suppose that 100 fruit flies are placed in a breeding container that can support at most 10,000 flies. Assuming that the population grows exponentially at a rate of 2% per day, how long will it take for the container to reach capacity?

**34.** Suppose that the town of Grayrock had a population of 10,000 in 2006 and a population of 12,000 in 2011. Assuming an exponential growth model, in what year will the population reach 20,000?

**35.** A scientist wants to determine the half-life of a certain radioactive substance. She determines that in exactly 5 days a 10.0-milligram sample of the substance decays to 3.5 milligrams. Based on these data, what is the half-life?

**36.** Suppose that 30% of a certain radioactive substance decays in 5 years.
(a) What is the half-life of the substance in years?
(b) Suppose that a certain quantity of this substance is stored in a cave. What percentage of it will remain after $t$ years?

**FOCUS ON CONCEPTS**

**37.** (a) Make a conjecture about the effect on the graphs of $y = y_0e^{kt}$ and $y = y_0e^{-kt}$ of varying $k$ and keeping $y_0$ fixed. Confirm your conjecture with a graphing utility.
(b) Make a conjecture about the effect on the graphs of $y = y_0e^{kt}$ and $y = y_0e^{-kt}$ of varying $y_0$ and keeping $k$ fixed. Confirm your conjecture with a graphing utility.

**38.** (a) What effect does increasing $y_0$ and keeping $k$ fixed have on the doubling time or half-life of an exponential model? Justify your answer.
(b) What effect does increasing $k$ and keeping $y_0$ fixed have on the doubling time and half-life of an exponential model? Justify your answer.

**39.** (a) There is a trick, called the ***Rule of 70***, that can be used to get a quick estimate of the doubling time or half-life of an exponential model. According to this rule, the doubling time or half-life is roughly 70 divided by the percentage growth or decay rate. For example, we showed in Example 5 that with a continued growth rate of 1.10% per year the world population would double every 63 years. This result agrees with the Rule of 70, since $70/1.10 \approx 63.6$. Explain why this rule works.
(b) Use the Rule of 70 to estimate the doubling time of a population that grows exponentially at a rate of 1% per year.
(c) Use the Rule of 70 to estimate the half-life of a population that decreases exponentially at a rate of 3.5% per hour.
(d) Use the Rule of 70 to estimate the growth rate that would be required for a population growing exponentially to double every 10 years.

**40.** Find a formula for the tripling time of an exponential growth model.

**41.** In 1950, a research team digging near Folsom, New Mexico, found charred bison bones along with some leaf-shaped projectile points (called the "Folsom points") that had been made by a Paleo-Indian hunting culture. It was clear from the evidence that the bison had been cooked and eaten by the makers of the points, so that carbon-14 dating of the bones made it possible for the researchers to determine when the hunters roamed North America. Tests showed that the bones contained between 27% and 30% of their original carbon-14. Use this information to show that the hunters lived roughly between 9000 B.C. and 8000 B.C.

**42.** (a) Use a graphing utility to make a graph of $p_{\text{rem}}$ versus $t$, where $p_{\text{rem}}$ is the percentage of carbon-14 that remains in an artifact after $t$ years.
(b) Use the graph to estimate the percentage of carbon-14 that would have to have been present in the 1988 test of the Shroud of Turin for it to have been the burial shroud of Jesus of Nazareth (see Example 7).

**43.** (a) It is currently accepted that the half-life of carbon-14 might vary $\pm 40$ years from its nominal value of 5730 years. Does this variation make it possible that the Shroud of Turin dates to the time of Jesus of Nazareth (see Example 7)?
(b) Review the subsection of Section 3.5 entitled Error Propagation, and then estimate the percentage error that

results in the computed age of an artifact from an $r\%$ error in the half-life of carbon-14.

**44.** Suppose that a quantity $y$ has an exponential growth model $y = y_0e^{kt}$ or an exponential decay model $y = y_0e^{-kt}$, and it is known that $y = y_1$ if $t = t_1$. In each case find a formula for $k$ in terms of $y_0$, $y_1$, and $t_1$, assuming that $t_1 \neq 0$.

**45.** (a) Show that if a quantity $y = y(t)$ has an exponential model, and if $y(t_1) = y_1$ and $y(t_2) = y_2$, then the doubling time or the half-life $T$ is

$$T = \left| \frac{(t_2 - t_1)\ln 2}{\ln(y_2/y_1)} \right|$$

(b) In a certain 1-hour period the number of bacteria in a colony increases by 25%. Assuming an exponential growth model, what is the doubling time for the colony?

**46.** Suppose that $P$ dollars is invested at an annual interest rate of $r \times 100\%$. If the accumulated interest is credited to the account at the end of the year, then the interest is said to be *compounded annually*; if it is credited at the end of each 6-month period, then it is said to be *compounded semiannually*; and if it is credited at the end of each 3-month period, then it is said to be *compounded quarterly*. The more frequently the interest is compounded, the better it is for the investor since more of the interest is itself earning interest.

(a) Show that if interest is compounded $n$ times a year at equally spaced intervals, then the value $A$ of the investment after $t$ years is

$$A = P\left(1 + \frac{r}{n}\right)^{nt}$$

(b) One can imagine interest to be compounded each day, each hour, each minute, and so forth. Carried to the limit one can conceive of interest compounded at each instant of time; this is called ***continuous compounding***. Thus, from part (a), the value $A$ of $P$ dollars after $t$ years when invested at an annual rate of $r \times 100\%$, compounded continuously, is

$$A = \lim_{n \to +\infty} P\left(1 + \frac{r}{n}\right)^{nt}$$

Use the fact that $\lim_{x \to 0}(1 + x)^{1/x} = e$ to prove that $A = Pe^{rt}$.

(c) Use the result in part (b) to show that money invested at continuous compound interest increases at a rate proportional to the amount present.

**47.** (a) If \$1000 is invested at 8% per year compounded continuously (Exercise 46), what will the investment be worth after 5 years?

(b) If it is desired that an investment at 8% per year compounded continuously should have a value of \$10,000 after 10 years, how much should be invested now?

(c) How long does it take for an investment at 8% per year compounded continuously to double in value?

**48.** What is the effective annual interest rate for an interest rate of $r\%$ per year compounded continuously?

**49.** Assume that $y = y(t)$ satisfies the logistic equation with $y_0 = y(0)$ the initial value of $y$.

(a) Use separation of variables to derive the solution

$$y = \frac{y_0 L}{y_0 + (L - y_0)e^{-kt}}$$

(b) Use part (a) to show that $\lim_{t \to +\infty} y(t) = L$.

**50.** Use your answer to Exercise 49 to derive a solution to the model for the spread of disease [Equation (6) of Section 8.1].

**51.** The graph of a solution to the logistic equation is known as a ***logistic curve***, and if $y_0 > 0$, it has one of four general shapes, depending on the relationship between $y_0$ and $L$. In each part, assume that $k = 1$ and use a graphing utility to plot a logistic curve satisfying the given condition.

(a) $y_0 > L$ (b) $y_0 = L$

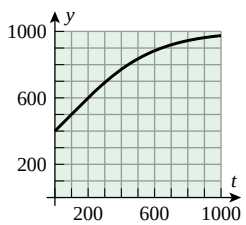
(c) $L/2 \leq y_0 < L$ (d) $0 < y_0 < L/2$

**52–53** The graph of a logistic model

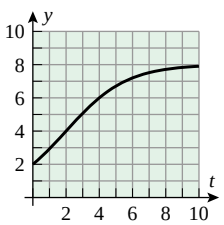
$$y = \frac{y_0 L}{y_0 + (L - y_0)e^{-kt}}$$

is shown. Estimate $y_0$, $L$, and $k$.

**52.**



**53.**



**54.** Plot a solution to the initial-value problem

$$\frac{dy}{dt} = 0.98\left(1 - \frac{y}{5}\right)y, \quad y_0 = 1$$

**55.** Suppose that the growth of a population $y = y(t)$ is given by the logistic equation

$$y = \frac{60}{5 + 7e^{-t}}$$

(a) What is the population at time $t = 0$?

(b) What is the carrying capacity $L$?

(c) What is the constant $k$?

(d) When does the population reach half of the carrying capacity?

(e) Find an initial-value problem whose solution is $y(t)$.

**56.** Suppose that the growth of a population $y = y(t)$ is given by the logistic equation

$$y = \frac{1000}{1 + 999e^{-0.9t}}$$

(a) What is the population at time $t = 0$?

(b) What is the carrying capacity $L$?

(c) What is the constant $k$?

(cont.)

(d) When does the population reach 75% of the carrying capacity?

(e) Find an initial-value problem whose solution is $y(t)$.

**57.** Suppose that a university residence hall houses 1000 students. Following the semester break, 20 students in the hall return with the flu, and 5 days later 35 students have the flu.

(a) Use the result of Exercise 50 to find the number of students who will have the flu $t$ days after returning to school.

(b) Make a table that illustrates how the flu spreads day to day over a 2-week period.

(c) Use a graphing utility to generate a graph that illustrates how the flu spreads over a 2-week period.

**58.** Suppose that at time $t = 0$ an object with temperature $T_0$ is placed in a room with constant temperature $T_a$. If $T_0 < T_a$, then the temperature of the object will increase, and if $T_0 > T_a$, then the temperature will decrease. Assuming that Newton's Law of Cooling applies, show that in both cases the temperature $T(t)$ at time $t$ is given by

$$T(t) = T_a + (T_0 - T_a)e^{-kt}$$

where $k$ is a positive constant.

**59.** A cup of water with a temperature of 95°C is placed in a room with a constant temperature of 21°C.

(a) Assuming that Newton's Law of Cooling applies, use the result of Exercise 58 to find the temperature of the water $t$ minutes after it is placed in the room. [*Note:* The solution will involve a constant of proportionality.]

(b) How many minutes will it take for the water to reach a temperature of 51°C if it cools to 85°C in 1 minute?

**60.** A glass of lemonade with a temperature of 40°F is placed in a room with a constant temperature of 70°F, and 1 hour later its temperature is 52°F. Show that $t$ hours after the lemonade is placed in the room its temperature is approximated by $T = 70 - 30e^{-0.5t}$.

**61.** A rocket, fired upward from rest at time $t = 0$, has an initial mass of $m_0$ (including its fuel). Assuming that the fuel is consumed at a constant rate $k$, the mass $m$ of the rocket, while fuel is being burned, will be given by $m = m_0 - kt$. It can be shown that if air resistance is neglected and the fuel gases are expelled at a constant speed $c$ relative to the rocket, then the velocity $v$ of the rocket will satisfy the equation

$$m\frac{dv}{dt} = ck - mg$$

where $g$ is the acceleration due to gravity.

(a) Find $v(t)$ keeping in mind that the mass $m$ is a function of $t$.

(b) Suppose that the fuel accounts for 80% of the initial mass of the rocket and that all of the fuel is consumed in 100 s. Find the velocity of the rocket in meters per second at the instant the fuel is exhausted. [*Note:* Take $g = 9.8$ m/s$^2$ and $c = 2500$ m/s.]

**62.** A bullet of mass $m$, fired straight up with an initial velocity of $v_0$, is slowed by the force of gravity and a drag force of air resistance $kv^2$, where $k$ is a positive constant. As the bullet moves upward, its velocity $v$ satisfies the equation

$$m\frac{dv}{dt} = -(kv^2 + mg)$$

where $g$ is the constant acceleration due to gravity.

(a) Show that if $x = x(t)$ is the height of the bullet above the barrel opening at time $t$, then

$$mv\frac{dv}{dx} = -(kv^2 + mg)$$

(b) Express $x$ in terms of $v$ given that $x = 0$ when $v = v_0$.

(c) Assuming that

$$v_0 = 988 \text{ m/s}, \quad g = 9.8 \text{ m/s}^2$$
$$m = 3.56 \times 10^{-3} \text{ kg}, \quad k = 7.3 \times 10^{-6} \text{ kg/m}$$

use the result in part (b) to find out how high the bullet rises. [*Hint:* Find the velocity of the bullet at its highest point.]

**63–64** Suppose that a tank containing a liquid is vented to the air at the top and has an outlet at the bottom through which the liquid can drain. It follows from ***Torricelli's law*** in physics that if the outlet is opened at time $t = 0$, then at each instant the depth of the liquid $h(t)$ and the area $A(h)$ of the liquid's surface are related by

$$A(h)\frac{dh}{dt} = -k\sqrt{h}$$

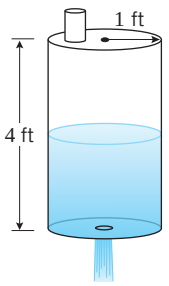
where $k$ is a positive constant that depends on such factors as the viscosity of the liquid and the cross-sectional area of the outlet. Use this result in these exercises, assuming that $h$ is in feet, $A(h)$ is in square feet, and $t$ is in seconds. ■

**63.** Suppose that the cylindrical tank in the accompanying figure is filled to a depth of 4 feet at time $t = 0$ and that the constant in Torricelli's law is $k = 0.025$.

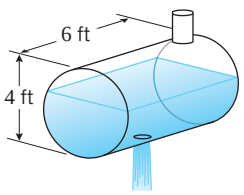
(a) Find $h(t)$.

(b) How many minutes will it take for the tank to drain completely?

**64.** Follow the directions of Exercise 63 for the cylindrical tank in the accompanying figure, assuming that the tank is filled to a depth of 4 feet at time $t = 0$ and that the constant in Torricelli's law is $k = 0.025$.



▲ Figure Ex-63



▲ Figure Ex-64

**65.** Suppose that a particle moving along the $x$-axis encounters a resisting force that results in an acceleration of $a = dv/dt = -\frac{1}{32}v^2$. If $x = 0$ cm and $v = 128$ cm/s at time $t = 0$, find the velocity $v$ and position $x$ as a function of $t$ for $t \geq 0$.

**66.** Suppose that a particle moving along the $x$-axis encounters a resisting force that results in an acceleration of $a = dv/dt = -0.02\sqrt{v}$. Given that $x = 0$ cm and $v = 9$ cm/s at time $t = 0$, find the velocity $v$ and position $x$ as a function of $t$ for $t \geq 0$.

**FOCUS ON CONCEPTS**

**67.** Use implicit differentiation to prove that any differentiable function defined implicitly by Equation (4) will be a solution to (1).

**68.** Prove that a solution to the initial-value problem

$$h(y)\frac{dy}{dx} = g(x), \quad y(x_0) = y_0$$

is defined implicitly by the equation

$$\int_{y_0}^{y} h(r)\,dr = \int_{x_0}^{x} g(s)\,ds$$

**69.** Let $L$ denote a tangent line at $(x, y)$ to a solution of Equation (1), and let $(x_1, y_1)$, $(x_2, y_2)$ denote any two points on $L$. Prove that Equation (2) is satisfied by $dy = \Delta y = y_2 - y_1$ and $dx = \Delta x = x_2 - x_1$.

**70. Writing** A student objects to the method of separation of variables because it often produces an equation in $x$ and $y$ instead of an explicit function $y = f(x)$. Discuss the pros and cons of this student's position.

**71. Writing** A student objects to Step 2 in the method of separation of variables because one side of the equation is integrated with respect to $x$ while the other side is integrated with respect to $y$. Answer this student's objection. [*Hint:* Recall the method of integration by substitution.]

## ✔ QUICK CHECK ANSWERS 8.2

**1.** Step 1: $h(y)\,dy = g(x)\,dx$; Step 2: $\int h(y)\,dy = \int g(x)\,dx$; Step 3: $H(y) = G(x) + C$ **2.** (a) $ky$ (b) $\dfrac{\ln 2}{k}$ (c) $y_0e^{kt}$ **3.** (a) $-ky$ (b) $\dfrac{\ln 2}{k}$ (c) $y_0e^{-kt}$ **4.** $y = \sqrt{1 - x^2}$

# 8.3 SLOPE FIELDS; EULER'S METHOD

*In this section we will reexamine the concept of a slope field and we will discuss a method for approximating solutions of first-order equations numerically. Numerical approximations are important in cases where the differential equation cannot be solved exactly.*

## FUNCTIONS OF TWO VARIABLES

We will be concerned here with first-order equations that are expressed with the derivative by itself on one side of the equation. For example,

$$y' = x^3 \quad \text{and} \quad y' = \sin(xy)$$

In applied problems involving time, it is usual to use $t$ as the independent variable, in which case one would be concerned with equations of the form $y' = f(t, y)$, where $y' = dy/dt$.

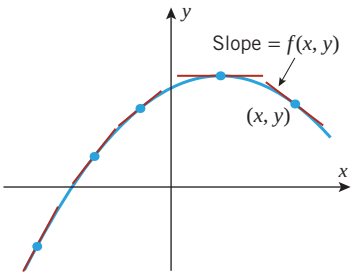
The first of these equations involves only $x$ on the right side, so it has the form $y' = f(x)$. However, the second equation involves both $x$ and $y$ on the right side, so it has the form $y' = f(x, y)$, where the symbol $f(x, y)$ stands for a function of the two variables $x$ and $y$. Later in the text we will study functions of two variables in more depth, but for now it will suffice to think of $f(x, y)$ as a formula that produces a unique output when values of $x$ and $y$ are given as inputs. For example, if

$$f(x, y) = x^2 + 3y$$

and if the inputs are $x = 2$ and $y = -4$, then the output is

$$f(2, -4) = 2^2 + 3(-4) = 4 - 12 = -8$$

## SLOPE FIELDS



At each point $(x, y)$ on an integral curve of $y' = f(x, y)$, the tangent line has slope $f(x, y)$.

▲ Figure 8.3.1

In Section 5.2 we introduced the concept of a slope field in the context of differential equations of the form $y' = f(x)$; the same principles apply to differential equations of the form

$$y' = f(x, y)$$

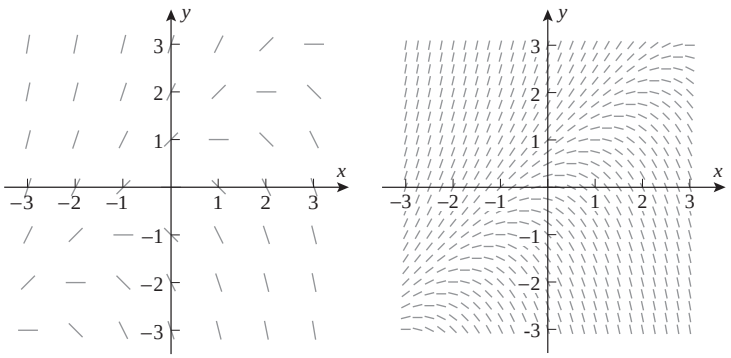
To see why this is so, let us review the basic idea. If we interpret $y'$ as the slope of a tangent line, then the differential equation states that at each point $(x, y)$ on an integral curve, the slope of the tangent line is equal to the value of $f$ at that point (Figure 8.3.1). For example, suppose that $f(x, y) = y - x$, in which case we have the differential equation

$$y' = y - x \tag{1}$$

A geometric description of the set of integral curves can be obtained by choosing a rectangular grid of points in the $xy$-plane, calculating the slopes of the tangent lines to the integral curves at the gridpoints, and drawing small segments of the tangent lines through those points. The resulting picture is called a ***slope field*** or a ***direction field*** for the differential equation because it shows the "slope" or "direction" of the integral curves at the gridpoints. The more gridpoints that are used, the better the description of the integral curves. For example, Figure 8.3.2 shows two slope fields for (1)—the first was obtained by hand calculation using the 49 gridpoints shown in the accompanying table, and the second, which gives a clearer picture of the integral curves, was obtained using 625 gridpoints and a CAS.

VALUES OF $f(x, y) = y - x$

| | $y = -3$ | $y = -2$ | $y = -1$ | $y = 0$ | $y = 1$ | $y = 2$ | $y = 3$ |
|---|---|---|---|---|---|---|---|
| $x = -3$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
| $x = -2$ | −1 | 0 | 1 | 2 | 3 | 4 | 5 |
| $x = -1$ | −2 | −1 | 0 | 1 | 2 | 3 | 4 |
| $x = 0$ | −3 | −2 | −1 | 0 | 1 | 2 | 3 |
| $x = 1$ | −4 | −3 | −2 | −1 | 0 | 1 | 2 |
| $x = 2$ | −5 | −4 | −3 | −2 | −1 | 0 | 1 |
| $x = 3$ | −6 | −5 | −4 | −3 | −2 | −1 | 0 |



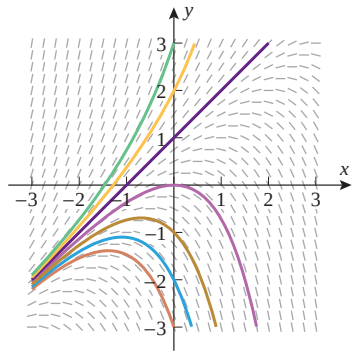
▲ Figure 8.3.2

It so happens that Equation (1) can be solved exactly using a method we will introduce in Section 8.4. We leave it for you to confirm that the general solution of this equation is

$$y = x + 1 + Ce^x \tag{2}$$

Confirm that the first slope field in Figure 8.3.2 is consistent with the accompanying table in that figure.

Figure 8.3.3 shows some of the integral curves superimposed on the slope field. Note that it was not necessary to have the general solution to construct the slope field. Indeed, slope fields are important precisely because they can be constructed in cases where the differential equation cannot be solved exactly.



▲ Figure 8.3.3

## EULER'S METHOD

Consider an initial-value problem of the form

$$y' = f(x, y), \quad y(x_0) = y_0$$

The slope field for the differential equation $y' = f(x, y)$ gives us a way to visualize the solution of the initial-value problem, since the graph of the solution is the integral curve that passes through the point $(x_0, y_0)$. The slope field will also help us to develop a method for approximating the solution to the initial-value problem numerically.

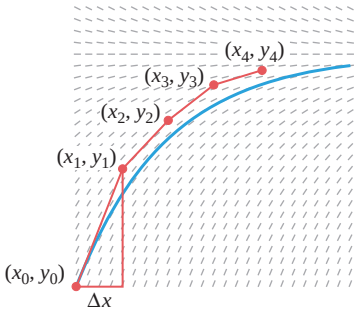
We will not attempt to approximate $y(x)$ for all values of $x$; rather, we will choose some small increment $\Delta x$ and focus on approximating the values of $y(x)$ at a succession of $x$-values spaced $\Delta x$ units apart, starting from $x_0$. We will denote these $x$-values by

$$x_1 = x_0 + \Delta x, \quad x_2 = x_1 + \Delta x, \quad x_3 = x_2 + \Delta x, \quad x_4 = x_3 + \Delta x, \ldots$$

and we will denote the approximations of $y(x)$ at these points by

$$y_1 \approx y(x_1), \quad y_2 \approx y(x_2), \quad y_3 \approx y(x_3), \quad y_4 \approx y(x_4), \ldots$$

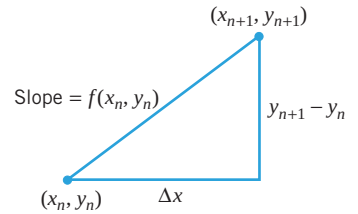
The technique that we will describe for obtaining these approximations is called ***Euler's Method***. Although there are better approximation methods available, many of them use Euler's Method as a starting point, so the underlying concepts are important to understand.



▲ Figure 8.3.4

The basic idea behind Euler's Method is to start at the known initial point $(x_0, y_0)$ and draw a line segment in the direction determined by the slope field until we reach the point $(x_1, y_1)$ with $x$-coordinate $x_1 = x_0 + \Delta x$ (Figure 8.3.4). If $\Delta x$ is small, then it is reasonable to expect that this line segment will not deviate much from the integral curve $y = y(x)$, and thus $y_1$ should closely approximate $y(x_1)$. To obtain the subsequent approximations, we repeat the process using the slope field as a guide at each step. Starting at the endpoint $(x_1, y_1)$, we draw a line segment determined by the slope field until we reach the point $(x_2, y_2)$ with $x$-coordinate $x_2 = x_1 + \Delta x$, and from that point we draw a line segment determined by the slope field to the point $(x_3, y_3)$ with $x$-coordinate $x_3 = x_2 + \Delta x$, and so forth. As indicated in Figure 8.3.4, this procedure produces a polygonal path that tends to follow the integral curve closely, so it is reasonable to expect that the $y$-values $y_2, y_3, y_4, \ldots$ will closely approximate $y(x_2), y(x_3), y(x_4), \ldots$.

To explain how the approximations $y_1, y_2, y_3, \ldots$ can be computed, let us focus on a typical line segment. As indicated in Figure 8.3.5, assume that we have found the point $(x_n, y_n)$, and we are trying to determine the next point $(x_{n+1}, y_{n+1})$, where $x_{n+1} = x_n + \Delta x$. Since the slope of the line segment joining the points is determined by the slope field at the starting point, the slope is $f(x_n, y_n)$, and hence



▲ Figure 8.3.5

$$\frac{y_{n+1} - y_n}{x_{n+1} - x_n} = \frac{y_{n+1} - y_n}{\Delta x} = f(x_n, y_n)$$

which we can rewrite as

$$y_{n+1} = y_n + f(x_n, y_n)\Delta x$$

This formula, which is the heart of Euler's Method, tells us how to use each approximation to compute the next approximation.

***Euler's Method***

To approximate the solution of the initial-value problem

$$y' = f(x, y), \quad y(x_0) = y_0$$

proceed as follows:

**Step 1.** Choose a nonzero number $\Delta x$ to serve as an ***increment*** or ***step size*** along the $x$-axis, and let

$$x_1 = x_0 + \Delta x, \quad x_2 = x_1 + \Delta x, \quad x_3 = x_2 + \Delta x, \ldots$$

**Step 2.** Compute successively

$$\begin{aligned} y_1 &= y_0 + f(x_0, y_0)\Delta x \\ y_2 &= y_1 + f(x_1, y_1)\Delta x \\ y_3 &= y_2 + f(x_2, y_2)\Delta x \\ &\vdots \\ y_{n+1} &= y_n + f(x_n, y_n)\Delta x \end{aligned}$$

The numbers $y_1, y_2, y_3, \ldots$ in these equations are the approximations of $y(x_1)$, $y(x_2)$, $y(x_3)$, ....

▶ **Example 1** Use Euler's Method with a step size of 0.1 to make a table of approximate values of the solution of the initial-value problem

$$y' = y - x, \quad y(0) = 2 \tag{3}$$

over the interval $0 \le x \le 1$.

***Solution.*** In this problem we have $f(x, y) = y - x$, $x_0 = 0$, and $y_0 = 2$. Moreover, since the step size is 0.1, the $x$-values at which the approximate values will be obtained are

$$x_1 = 0.1, \quad x_2 = 0.2, \quad x_3 = 0.3, \ldots, \quad x_9 = 0.9, \quad x_{10} = 1$$

The first three approximations are

$$\begin{aligned} y_1 &= y_0 + f(x_0, y_0)\Delta x = 2 + (2 - 0)(0.1) = 2.2 \\ y_2 &= y_1 + f(x_1, y_1)\Delta x = 2.2 + (2.2 - 0.1)(0.1) = 2.41 \\ y_3 &= y_2 + f(x_2, y_2)\Delta x = 2.41 + (2.41 - 0.2)(0.1) = 2.631 \end{aligned}$$

Here is a way of organizing all 10 approximations rounded to five decimal places:

EULER'S METHOD FOR $y' = y - x$, $y(0) = 2$ WITH $\Delta x = 0.1$

| $n$ | $x_n$ | $y_n$ | $f(x_n, y_n)\Delta x$ | $y_{n+1} = y_n + f(x_n, y_n)\Delta x$ |
|---|---|---|---|---|
| 0 | 0 | 2.00000 | 0.20000 | 2.20000 |
| 1 | 0.1 | 2.20000 | 0.21000 | 2.41000 |
| 2 | 0.2 | 2.41000 | 0.22100 | 2.63100 |
| 3 | 0.3 | 2.63100 | 0.23310 | 2.86410 |
| 4 | 0.4 | 2.86410 | 0.24641 | 3.11051 |
| 5 | 0.5 | 3.11051 | 0.26105 | 3.37156 |
| 6 | 0.6 | 3.37156 | 0.27716 | 3.64872 |
| 7 | 0.7 | 3.64872 | 0.29487 | 3.94359 |
| 8 | 0.8 | 3.94359 | 0.31436 | 4.25795 |
| 9 | 0.9 | 4.25795 | 0.33579 | 4.59374 |
| 10 | 1.0 | 4.59374 | — | — |

Observe that each entry in the last column becomes the next entry in the third column. This is reminiscent of Newton's Method in which each successive approximation is used to find the next. ◀

## ACCURACY OF EULER'S METHOD

As a rule of thumb, the absolute error in an approximation produced by Euler's Method is proportional to the step size. Thus, reducing the step size by half reduces the absolute and percentage errors by roughly half. However, reducing the step size increases the amount of computation, thereby increasing the potential for more roundoff error. Such matters are discussed in courses on differential equations or numerical analysis.

It follows from (3) and the initial condition $y(0) = 2$ that the exact solution of the initial-value problem in Example 1 is

$$y = x + 1 + e^x$$

Thus, in this case we can compare the approximate values of $y(x)$ produced by Euler's Method with decimal approximations of the exact values (Table 8.3.1). In Table 8.3.1 the ***absolute error*** is calculated as

$$|\text{exact value} - \text{approximation}|$$

and the ***percentage error*** as

$$\frac{|\text{exact value} - \text{approximation}|}{|\text{exact value}|} \times 100\%$$

Notice that the absolute error tends to increase as $x$ moves away from $x_0$.

**Table 8.3.1**

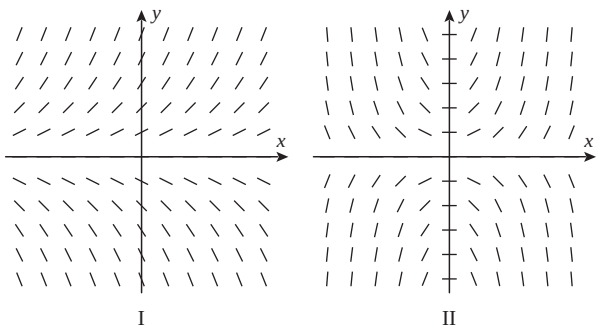
| $x$ | EXACT SOLUTION | EULER APPROXIMATION | ABSOLUTE ERROR | PERCENTAGE ERROR |
|---|---|---|---|---|
| 0 | 2.00000 | 2.00000 | 0.00000 | 0.00 |
| 0.1 | 2.20517 | 2.20000 | 0.00517 | 0.23 |
| 0.2 | 2.42140 | 2.41000 | 0.01140 | 0.47 |
| 0.3 | 2.64986 | 2.63100 | 0.01886 | 0.71 |
| 0.4 | 2.89182 | 2.86410 | 0.02772 | 0.96 |
| 0.5 | 3.14872 | 3.11051 | 0.03821 | 1.21 |
| 0.6 | 3.42212 | 3.37156 | 0.05056 | 1.48 |
| 0.7 | 3.71375 | 3.64872 | 0.06503 | 1.75 |
| 0.8 | 4.02554 | 3.94359 | 0.08195 | 2.04 |
| 0.9 | 4.35960 | 4.25795 | 0.10165 | 2.33 |
| 1.0 | 4.71828 | 4.59374 | 0.12454 | 2.64 |

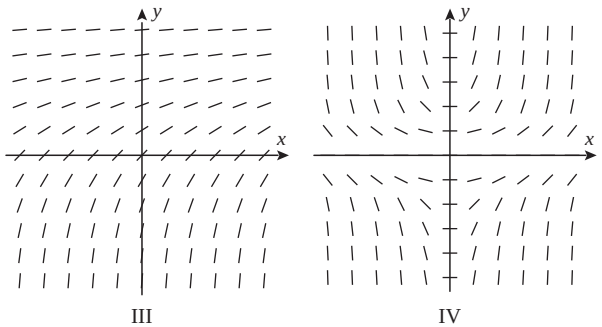
## ✔ QUICK CHECK EXERCISES 8.3 (See page 586 for answers.)

**1.** Match each differential equation with its slope field.

(a) $y' = 2xy^2$ _____ (b) $y' = e^{-y}$ _____

(c) $y' = y$ _____ (d) $y' = 2xy$ _____

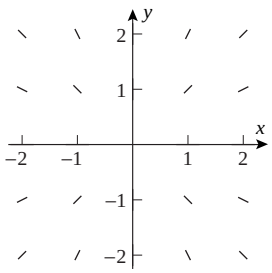




▲ **Figure Ex-1**

**2.** The slope field for $y' = y/x$ at the 16 gridpoints $(x, y)$, where $x = -2, -1, 1, 2$ and $y = -2, -1, 1, 2$ is shown in

the accompanying figure. Use this slope field and geometric reasoning to find the integral curve that passes through the point (1, 2).



◀ **Figure Ex-2**

**3.** When using Euler's Method on the initial-value problem $y' = f(x, y)$, $y(x_0) = y_0$, we obtain $y_{n+1}$ from $y_n$, $x_n$, and $\Delta x$ by means of the formula $y_{n+1} =$ _____.

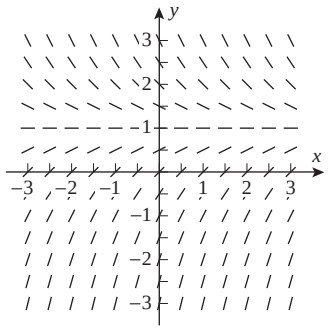
**4.** Consider the initial-value problem $y' = y$, $y(0) = 1$.
(a) Use Euler's Method with two steps to approximate $y(1)$.
(b) What is the exact value of $y(1)$?

## EXERCISE SET 8.3 Graphing Utility

**1.** Sketch the slope field for $y' = xy/4$ at the 25 gridpoints $(x, y)$, where $x = -2, -1, \ldots, 2$ and $y = -2, -1, \ldots, 2$.

**2.** Sketch the slope field for $y' + y = 2$ at the 25 gridpoints $(x, y)$, where $x = 0, 1, \ldots, 4$ and $y = 0, 1, \ldots, 4$.

**3.** A slope field for the differential equation $y' = 1 - y$ is shown in the accompanying figure. In each part, sketch the graph of the solution that satisfies the initial condition.
(a) $y(0) = -1$ (b) $y(0) = 1$ (c) $y(0) = 2$



◀ **Figure Ex-3**

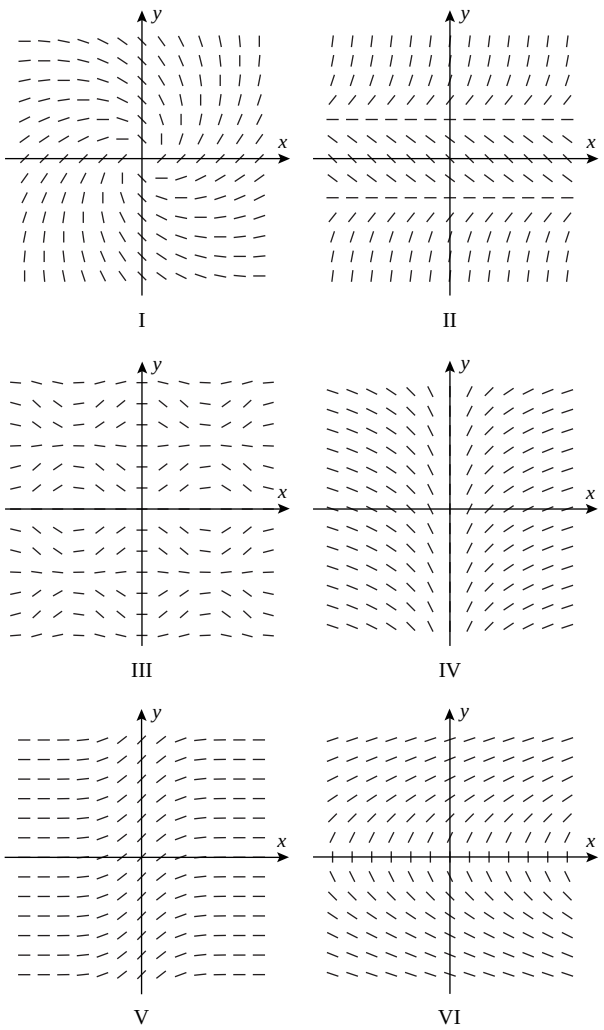
**4.** Solve the initial-value problems in Exercise 3, and use a graphing utility to confirm that the integral curves for these solutions are consistent with the sketches you obtained from the slope field.

### FOCUS ON CONCEPTS

**5.** Use the slope field in Exercise 3 to make a conjecture about the behavior of the solutions of $y' = 1 - y$ as $x \to +\infty$, and confirm your conjecture by examining the general solution of the equation.

**6.** In parts (a)–(f), match the differential equation with the slope field, and explain your reasoning.
(a) $y' = 1/x$ (b) $y' = 1/y$
(c) $y' = e^{-x^2}$ (d) $y' = y^2 - 1$

(e) $y' = \dfrac{x + y}{x - y}$ (f) $y' = (\sin x)(\sin y)$



▲ **Figure Ex-6**

**7–10** Use Euler's Method with the given step size $\Delta x$ or $\Delta t$ to approximate the solution of the initial-value problem over the stated interval. Present your answer as a table and as a graph.

**7.** $dy/dx = \sqrt[3]{y},\ y(0) = 1,\ 0 \le x \le 4,\ \Delta x = 0.5$

**8.** $dy/dx = x - y^2,\ y(0) = 1,\ 0 \le x \le 2,\ \Delta x = 0.25$

**9.** $dy/dt = \cos y,\ y(0) = 1,\ 0 \le t \le 2,\ \Delta t = 0.5$

**10.** $dy/dt = e^{-y},\ y(0) = 0,\ 0 \le t \le 1,\ \Delta t = 0.1$

**11.** Consider the initial-value problem

$$y' = \sin \pi t, \quad y(0) = 0$$

Use Euler's Method with five steps to approximate $y(1)$.

**12–15 True–False** Determine whether the statement is true or false. Explain your answer.

**12.** If the graph of $y = f(x)$ is an integral curve for a slope field, then so is any vertical translation of this graph.

**13.** Every integral curve for the slope field $dy/dx = e^{xy}$ is the graph of an increasing function of $x$.

**14.** Every integral curve for the slope field $dy/dx = e^{y}$ is concave up.

**15.** If $p(y)$ is a cubic polynomial in $y$, then the slope field $dy/dx = p(y)$ has an integral curve that is a horizontal line.

## FOCUS ON CONCEPTS

**16.** (a) Show that the solution of the initial-value problem $y' = e^{-x^2}$, $y(0) = 0$ is

$$y(x) = \int_0^x e^{-t^2}\,dt$$

(b) Use Euler's Method with $\Delta x = 0.05$ to approximate the value of

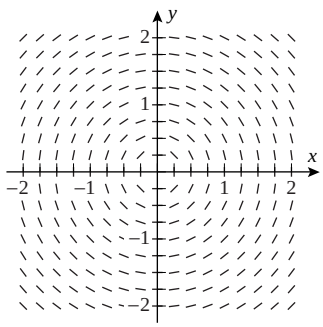
$$y(1) = \int_0^1 e^{-t^2}\,dt$$

and compare the answer to that produced by a calculating utility with a numerical integration capability.

**17.** The accompanying figure shows a slope field for the differential equation $y' = -x/y$.

(a) Use the slope field to estimate $y\left(\frac{1}{2}\right)$ for the solution that satisfies the given initial condition $y(0) = 1$.

(b) Compare your estimate to the exact value of $y\left(\frac{1}{2}\right)$.



◀ **Figure Ex-17**

**18.** Refer to slope field II in Quick Check Exercise 1.

(a) Does the slope field appear to have a horizontal line as an integral curve?

(b) Use the differential equation for the slope field to verify your answer to part (a).

**19.** Refer to the slope field in Exercise 3 and consider the integral curve through $(0, -1)$.

(a) Use the slope field to estimate where the integral curve intersects the $x$-axis.

(b) Compare your estimate in part (a) with the exact value of the $x$-intercept for the integral curve.

**20.** Consider the initial-value problem

$$\frac{dy}{dx} = \frac{\sqrt{y}}{2}, \quad y(0) = 1$$

(a) Use Euler's Method with step sizes of $\Delta x = 0.2$, 0.1, and 0.05 to obtain three approximations of $y(1)$.

(b) Find $y(1)$ exactly.

**21.** A slope field of the form $y' = f(y)$ is said to be ***autonomous***.

(a) Explain why the tangent segments along any horizontal line will be parallel for an autonomous slope field.

(b) The word *autonomous* means "independent." In what sense is an autonomous slope field independent?

(c) Suppose that $G(y)$ is an antiderivative of $1/[f(y)]$ and that $C$ is a constant. Explain why any differentiable function defined implicitly by $G(y) - x = C$ will be a solution to the equation $y' = f(y)$.

**22.** (a) Solve the equation $y' = \sqrt{y}$ and show that every nonconstant solution has a graph that is everywhere concave up.

(b) Explain how the conclusion in part (a) may be obtained directly from the equation $y' = \sqrt{y}$ without solving.

**23.** (a) Find a slope field whose integral curve through $(1, 1)$ satisfies $xy^3 - x^2y = 0$ by differentiating this equation implicitly.

(b) Prove that if $y(x)$ is any integral curve of the slope field in part (a), then $x[y(x)]^3 - x^2y(x)$ will be a constant function.

(c) Find an equation that implicitly defines the integral curve through $(-1, -1)$ of the slope field in part (a).

**24.** (a) Find a slope field whose integral curve through $(0, 0)$ satisfies $xe^y + ye^x = 0$ by differentiating this equation implicitly.

(b) Prove that if $y(x)$ is any integral curve of the slope field in part (a), then $xe^{y(x)} + y(x)e^x$ will be a constant function.

(c) Find an equation that implicitly defines the integral curve through $(1, 1)$ of the slope field in part (a).

**25.** Consider the initial-value problem $y' = y,\ y(0) = 1$, and let $y_n$ denote the approximation of $y(1)$ using Euler's Method with $n$ steps.
(a) What would you conjecture is the exact value of $\lim_{n\to+\infty} y_n$? Explain your reasoning.
(b) Find an explicit formula for $y_n$ and use it to verify your conjecture in part (a).

**26. Writing** Explain the connection between Euler's Method and the local linear approximation discussed in Section 3.5.

**27. Writing** Given a slope field, what features of an integral curve might be discussed from the slope field? Apply your ideas to the slope field in Exercise 3.

# 8.4 FIRST-ORDER DIFFERENTIAL EQUATIONS AND APPLICATIONS

*In this section we will discuss a general method that can be used to solve a large class of first-order differential equations. We will use this method to solve differential equations related to the problems of mixing liquids and free fall retarded by air resistance.*

## FIRST-ORDER LINEAR EQUATIONS

The simplest first-order equations are those that can be written in the form

$$\frac{dy}{dx} = q(x) \tag{1}$$

Such equations can often be solved by integration. For example, if

$$\frac{dy}{dx} = x^3 \tag{2}$$

then

$$y = \int x^3\,dx = \frac{x^4}{4} + C$$

is the general solution of (2) on the interval $(-\infty, +\infty)$. More generally, a first-order differential equation is called ***linear*** if it is expressible in the form

$$\frac{dy}{dx} + p(x)y = q(x) \tag{3}$$

Equation (1) is the special case of (3) that results when the function $p(x)$ is identically 0. Some other examples of first-order linear differential equations are

$$\frac{dy}{dx} + x^2 y = e^x, \qquad \frac{dy}{dx} + (\sin x)y + x^3 = 0, \qquad \frac{dy}{dx} + 5y = 2$$

$p(x) = x^2, q(x) = e^x$ $\quad$ $p(x) = \sin x, q(x) = -x^3$ $\quad$ $p(x) = 5, q(x) = 2$

We will assume that the functions $p(x)$ and $q(x)$ in (3) are continuous on a common interval, and we will look for a general solution that is valid on that interval. One method for doing this is based on the observation that if we define $\mu = \mu(x)$ by

$$\mu = e^{\int p(x)\,dx} \tag{4}$$

then

$$\frac{d\mu}{dx} = e^{\int p(x)\,dx} \cdot \frac{d}{dx}\int p(x)\,dx = \mu p(x)$$

Thus,

$$\frac{d}{dx}(\mu y) = \mu\frac{dy}{dx} + \frac{d\mu}{dx}y = \mu\frac{dy}{dx} + \mu p(x)y \tag{5}$$

If (3) is multiplied through by $\mu$, it becomes

$$\mu\frac{dy}{dx} + \mu p(x)y = \mu q(x)$$

Combining this with (5) we have

$$\frac{d}{dx}(\mu y) = \mu q(x) \tag{6}$$

This equation can be solved for $y$ by integrating both sides with respect to $x$ and then dividing through by $\mu$ to obtain

$$y = \frac{1}{\mu}\int \mu q(x)\,dx \tag{7}$$

which is a general solution of (3) on the interval. The function $\mu$ in (4) is called an ***integrating factor*** for (3), and this method for finding a general solution of (3) is called the ***method of integrating factors***. Although one could simply memorize Formula (7), we recommend solving first-order linear equations by actually carrying out the steps used to derive this formula:

***The Method of Integrating Factors***

**Step 1.** Calculate the integrating factor

$$\mu = e^{\int p(x)\,dx}$$

Since any $\mu$ will suffice, we can take the constant of integration to be zero in this step.

**Step 2.** Multiply both sides of (3) by $\mu$ and express the result as

$$\frac{d}{dx}(\mu y) = \mu q(x)$$

**Step 3.** Integrate both sides of the equation obtained in Step 2 and then solve for $y$. Be sure to include a constant of integration in this step.

▶ **Example 1** Solve the differential equation

$$\frac{dy}{dx} - y = e^{2x}$$

***Solution.*** Comparing the given equation to (3), we see that we have a first-order linear equation with $p(x) = -1$ and $q(x) = e^{2x}$. These coefficients are continuous on the interval $(-\infty, +\infty)$, so the method of integrating factors will produce a general solution on this interval. The first step is to compute the integrating factor. This yields

$$\mu = e^{\int p(x)\,dx} = e^{\int(-1)\,dx} = e^{-x}$$

Next we multiply both sides of the given equation by $\mu$ to obtain

$$e^{-x}\frac{dy}{dx} - e^{-x}y = e^{-x}e^{2x}$$

which we can rewrite as

$$\frac{d}{dx}[e^{-x}y] = e^{x}$$

Integrating both sides of this equation with respect to $x$ we obtain

$$e^{-x}y = e^{x} + C$$

Finally, solving for $y$ yields the general solution

$$y = e^{2x} + Ce^{x} \quad \blacktriangleleft$$

Confirm that the solution obtained in Example 1 agrees with that obtained by substituting the integrating factor into Formula (7).

A differential equation of the form

$$P(x)\frac{dy}{dx} + Q(x)y = R(x)$$

can be solved by dividing through by $P(x)$ to put the equation in the form of (3) and then applying the method of integrating factors. However, the resulting solution will only be valid on intervals where $p(x) = Q(x)/P(x)$ and $q(x) = R(x)/P(x)$ are both continuous.

**▶ Example 2** Solve the initial-value problem

$$x\frac{dy}{dx} - y = x, \quad y(1) = 2$$

***Solution.*** This differential equation can be written in the form of (3) by dividing through by $x$. This yields

$$\frac{dy}{dx} - \frac{1}{x}y = 1 \tag{8}$$

where $q(x) = 1$ is continuous on $(-\infty, +\infty)$ and $p(x) = -1/x$ is continuous on $(-\infty, 0)$ and $(0, +\infty)$. Since we need $p(x)$ and $q(x)$ to be continuous on a common interval, and since our initial condition requires a solution for $x = 1$, we will find a general solution of (8) on the interval $(0, +\infty)$. On this interval we have $|x| = x$, so that

$$\int p(x)\,dx = -\int \frac{1}{x}\,dx = -\ln|x| = -\ln x$$

Taking the constant of integration to be 0

Thus, an integrating factor that will produce a general solution on the interval $(0, +\infty)$ is

$$\mu = e^{\int p(x)\,dx} = e^{-\ln x} = e^{\ln(1/x)} = \frac{1}{x}$$

Multiplying both sides of Equation (8) by this integrating factor yields

$$\frac{1}{x}\frac{dy}{dx} - \frac{1}{x^2}y = \frac{1}{x}$$

or

$$\frac{d}{dx}\left[\frac{1}{x}y\right] = \frac{1}{x}$$

It is not accidental that the initial-value problem in Example 2 has a unique solution. If the coefficients of (3) are continuous on an open interval that contains the point $x_0$, then for any $y_0$ there will be a unique solution of (3) on that interval that satisfies the initial condition $y(x_0) = y_0$ [Exercise 29(b)].

Therefore, on the interval $(0, +\infty)$,

$$\frac{1}{x}y = \int \frac{1}{x}\,dx = \ln x + C$$

from which it follows that

$$y = x \ln x + Cx \tag{9}$$

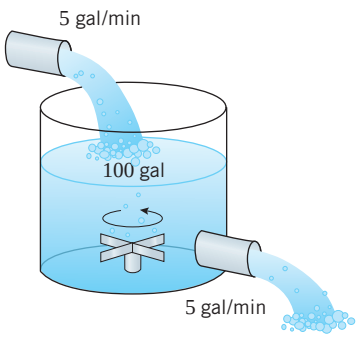
The initial condition $y(1) = 2$ requires that $y = 2$ if $x = 1$. Substituting these values into (9) and solving for $C$ yields $C = 2$ (verify), so the solution of the initial-value problem is

$$y = x \ln x + 2x \quad \blacktriangleleft$$

We conclude this section with some applications of first-order differential equations.

## MIXING PROBLEMS

In a typical mixing problem, a tank is filled to a specified level with a solution that contains a known amount of some soluble substance (say salt). The thoroughly stirred solution is allowed to drain from the tank at a known rate, and at the same time a solution with a known concentration of the soluble substance is added to the tank at a known rate that may or may not differ from the draining rate. As time progresses, the amount of the soluble substance in the tank will generally change, and the usual mixing problem seeks to determine the amount of the substance in the tank at a specified time. This type of problem serves as a model for many kinds of problems: discharge and filtration of pollutants in a river, injection and absorption of medication in the bloodstream, and migrations of species into and out of an ecological system, for example.



▲ Figure 8.4.1

▶ **Example 3** At time $t = 0$, a tank contains 4 lb of salt dissolved in 100 gal of water. Suppose that brine containing 2 lb of salt per gallon of brine is allowed to enter the tank at a rate of 5 gal/min and that the mixed solution is drained from the tank at the same rate (Figure 8.4.1). Find the amount of salt in the tank after 10 minutes.

***Solution.*** Let $y(t)$ be the amount of salt (in pounds) after $t$ minutes. We are given that $y(0) = 4$, and we want to find $y(10)$. We will begin by finding a differential equation that is satisfied by $y(t)$. To do this, observe that $dy/dt$, which is the rate at which the amount of salt in the tank changes with time, can be expressed as

$$\frac{dy}{dt} = \text{rate in} - \text{rate out} \tag{10}$$

where *rate in* is the rate at which salt enters the tank and *rate out* is the rate at which salt leaves the tank. But the rate at which salt enters the tank is

$$\text{rate in} = (2 \text{ lb/gal}) \cdot (5 \text{ gal/min}) = 10 \text{ lb/min}$$

Since brine enters and drains from the tank at the same rate, the volume of brine in the tank stays constant at 100 gal. Thus, after $t$ minutes have elapsed, the tank contains $y(t)$ lb of salt per 100 gal of brine, and hence the rate at which salt leaves the tank at that instant is

$$\text{rate out} = \left(\frac{y(t)}{100} \text{ lb/gal}\right) \cdot (5 \text{ gal/min}) = \frac{y(t)}{20} \text{ lb/min}$$

Therefore, (10) can be written as

$$\frac{dy}{dt} = 10 - \frac{y}{20} \qquad \text{or} \qquad \frac{dy}{dt} + \frac{y}{20} = 10$$

which is a first-order linear differential equation satisfied by $y(t)$. Since we are given that $y(0) = 4$, the function $y(t)$ can be obtained by solving the initial-value problem

$$\frac{dy}{dt} + \frac{y}{20} = 10, \quad y(0) = 4$$

The integrating factor for the differential equation is

$$\mu = e^{\int (1/20)\,dt} = e^{t/20}$$

If we multiply the differential equation through by $\mu$, then we obtain

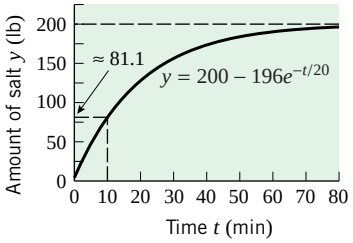
$$\frac{d}{dt}(e^{t/20}y) = 10e^{t/20}$$

$$e^{t/20}y = \int 10e^{t/20}\,dt = 200e^{t/20} + C$$

$$y(t) = 200 + Ce^{-t/20} \tag{11}$$

The initial condition states that $y = 4$ when $t = 0$. Substituting these values into (11) and solving for $C$ yields $C = -196$ (verify), so

$$y(t) = 200 - 196e^{-t/20} \tag{12}$$



▲ **Figure 8.4.2**

The graph of (12) is shown in Figure 8.4.2. At time $t = 10$ the amount of salt in the tank is

$$y(10) = 200 - 196e^{-0.5} \approx 81.1 \text{ lb} \quad \blacktriangleleft$$

Notice that it follows from (11) that

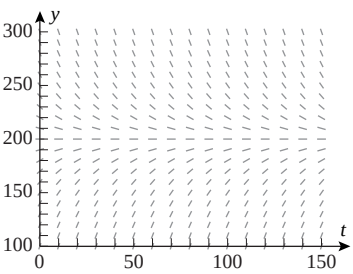
$$\lim_{t \to +\infty} y(t) = 200$$

for all values of $C$, so regardless of the amount of salt that is present in the tank initially, the amount of salt in the tank will eventually stabilize at 200 lb. This can also be seen geometrically from the slope field for the differential equation shown in Figure 8.4.3. This slope field suggests the following: If the amount of salt present in the tank is greater than 200 lb initially, then the amount of salt will decrease steadily over time toward a limiting value of 200 lb; and if the amount of salt is less than 200 lb initially, then it will increase steadily toward a limiting value of 200 lb. The slope field also suggests that if the amount present initially is exactly 200 lb, then the amount of salt in the tank will stay constant at 200 lb. This can also be seen from (11), since $C = 0$ in this case (verify).

The graph shown in Figure 8.4.2 suggests that $y(t) \to 200$ as $t \to +\infty$. This means that over an extended period of time the amount of salt in the tank tends toward 200 lb. Give an informal physical argument to explain why this result is to be expected.

## A MODEL OF FREE-FALL MOTION RETARDED BY AIR RESISTANCE

In Section 5.7 we considered the free-fall model of an object moving along a vertical axis near the surface of the Earth. It was assumed in that model that there is no air resistance and that the only force acting on the object is the Earth's gravity. Our goal here is to find a model that takes air resistance into account. For this purpose we make the following assumptions:



▲ **Figure 8.4.3**

- The object moves along a vertical $s$-axis whose origin is at the surface of the Earth and whose positive direction is up (Figure 5.7.7).
- At time $t = 0$ the height of the object is $s_0$ and the velocity is $v_0$.
- The only forces on the object are the force $F_G = -mg$ of the Earth's gravity acting down and the force $F_R$ of air resistance acting opposite to the direction of motion. The force $F_R$ is called the ***drag force***.

In the case of free-fall motion retarded by air resistance, the net force acting on the object is

$$F_G + F_R = -mg + F_R$$

and the acceleration is $d^2s/dt^2$, so Newton's Second Law of Motion [Equation (5) of Section 6.6] implies that

$$-mg + F_R = m\frac{d^2s}{dt^2} \tag{13}$$

Experimentation has shown that the force $F_R$ of air resistance depends on the shape of the object and its speed—the greater the speed, the greater the drag force. There are many possible models for air resistance, but one of the most basic assumes that the drag force $F_R$ is proportional to the velocity of the object, that is,

$$F_R = -cv$$

where $c$ is a positive constant that depends on the object's shape and properties of the air.* (The minus sign ensures that the drag force is opposite to the direction of motion.) Substituting this in (13) and writing $d^2s/dt^2$ as $dv/dt$, we obtain

$$-mg - cv = m\frac{dv}{dt}$$

Dividing by $m$ and rearranging we obtain

$$\frac{dv}{dt} + \frac{c}{m}v = -g$$

which is a first-order linear differential equation in the unknown function $v = v(t)$ with $p(t) = c/m$ and $q(t) = -g$ [see (3)]. For a specific object, the coefficient $c$ can be determined experimentally, so we will assume that $m$, $g$, and $c$ are known constants. Thus, the velocity function $v = v(t)$ can be obtained by solving the initial-value problem

$$\frac{dv}{dt} + \frac{c}{m}v = -g, \quad v(0) = v_0 \tag{14}$$

Once the velocity function is found, the position function $s = s(t)$ can be obtained by solving the initial-value problem

$$\frac{ds}{dt} = v(t), \quad s(0) = s_0 \tag{15}$$

In Exercise 25 we will ask you to solve (14) and show that

$$v(t) = e^{-ct/m}\left(v_0 + \frac{mg}{c}\right) - \frac{mg}{c} \tag{16}$$

Note that

$$\lim_{t \to +\infty} v(t) = -\frac{mg}{c} \tag{17}$$

(verify). Thus, the speed $|v(t)|$ does not increase indefinitely, as in free fall; rather, because of the air resistance, it approaches a finite limiting speed $v_\tau$ given by

$$v_\tau = \left|-\frac{mg}{c}\right| = \frac{mg}{c} \tag{18}$$

This is called the ***terminal speed*** of the object, and (17) is called its ***terminal velocity***.

**REMARK** Intuition suggests that near the limiting velocity, the velocity $v(t)$ changes very slowly; that is, $dv/dt \approx 0$. Thus, it should not be surprising that the limiting velocity can be obtained informally from (14) by setting $dv/dt = 0$ in the differential equation and solving for $v$. This yields

$$v = -\frac{mg}{c}$$

which agrees with (17).

*Other common models assume that $F_R = -cv^2$ or, more generally, $F_R = -cv^p$ for some value of $p$.
